 Wellington, J. B. B., Elstree.
 Werner, A., Dublin.

A cordial vote of thanks was passed to Mr. F. A. Bridge (London), General Secretary and Treasurer, for his labours in connection with the Convention.

Mr. Bridge suitably acknowledged the compliment.
 A meeting of the newly elected Council was then held.
 Sir Howard and Lady Grubb gave a garden party on Wednesday afternoon in the Zoological Gardens in connection with the Photographic Convention. The function was favoured with fine weather, and light refreshments were served in a number of tents erected on the grounds. During the afternoon a charming programme of music was performed by the band of the Dublin Metropolitan Police. The group of members of the Convention was afterwards photographed by Mr. Alfred Werner, and is reproduced as a supplement to this issue.

The annual dinner of the Convention was held in the Gresham Hotel in the evening. Dr. Joly presided, and to his right were Sir Howard Grubb, Mr. W. E. Wilson, Colonel Plunkett, Mr. Moss, and Mr. Bothamley. To his left were the President of the Royal College of Physicians (Dr. Wm. Smyly), Sir Charles Cameron, Colonel Plunkett, and Dr. Robert Browne. The company was large.

The usual loyal toasts having been honoured,
 Sir Charles Cameron proposed the toast of "The Photographic Convention of the United Kingdom." He said that the art was widely diffused, and had numerous applications. In no profession was the value of photography more valuable than in the medical and surgical profession, where, in the form of the Röntgen Rays, it had worked wonders.

Mr. Bridge responded, and in conclusion he gave the toast of "The Photographic Society of Ireland."

Dr. Scott responded.
 Mr. C. H. Bothamley gave the toast of "The President, Professor Joly," and eulogised the work done by Dr. Joly in the world of science.

Count Plunkett gave the toast of "The Press," which was responded to by Mr. George E. Brown (THE BRITISH JOURNAL OF PHOTOGRAPHY).

Colonel Plunkett gave the toast of "The Ladies," which was responded to by Mrs. Catherine Weed Ward.

During the evening many excellent musical contributions were given. Mr. Clarke Barry's band supplied a programme of music during the dinner, and after dinner Mr. Gerald Ewing and Mr. Fred Jeffs contributed notably to the enjoyment of the company by some excellent songs. The latter also amused his hearers very much as a *raconteur*. The remarkable sleight-of-hand performances of Mr. W. E. Cooper ("Presto") further diversified the entertainment very agreeably, and formed a distinct feature of a thoroughly enjoyable evening.

On Thursday an excursion was made to Bray and the Dargle, and in the evening an illustrated lecture was delivered in Trinity College by Dr. E. MacDonald Cosgrave on "Old Dublin." Friday's excursion was to Drogheda and Monasterboice, and on the evening of that day a paper was read by Mr. T. Thorne Baker. Saturday is always a miscellaneous day at the Convention, and was spent in brief excursions in and around Dublin. A number of conventioners prolonged their visit to Ireland for some time, and on Saturday betook themselves to Killarney and other parts of the country.

THE USE OF EXTREMELY RAPID PLATES.

(A Paper read before the Photographic Convention on July 15.)

The attainment of any given object is invariably attended by some counterbalancing disadvantage, and this is perhaps truer of no case than that of dry plates, in which certain qualities must be sacrificed in order to endow the plates with excessive speed. Every so-called photographic season has its pet "rage," and the nature of each new rage is made evident to the manufacturer by the special requests of his clients. Thus three years ago gaslight development papers were very much in vogue, two years ago everyone was deeply interested in orthochromatic photography, and nowadays every photographer requires the very fastest plate he or she can possibly get hold of.

The use of plates possessing very great speed is only advisable when the object in view justifies it. Thus the photography of children in the studio is an example; the photographing of such subjects as sports on a dull day; and in focal-plane shutter work it is obvious that a high-speed plate is practically essential. The indiscriminate use of very rapid plates is certainly inadvisable, as it is very difficult to get with them the variety of classes of negatives one can obtain with slow plates. This will be clear from the following points of difference which exist between slow and rapid plates.

The Properties of Slow and Fast Plates.

A slow plate, i.e., one of from 50 to 75 H. and D. (ferrous oxalate), has very little tendency to fog in development. It has a fine grain, and is therefore capable of giving considerable density in a short time, as with small granules of silver bromide the developer can readily reduce to metallic silver the entire granule. The slow plate further has a steep gradation curve—that is to say, contrasts come very readily, whilst details in the shadows only appear with full exposure, and, what is more important yet, reversal takes place only after very considerable over-exposure.

With plates in which no effort has been spared to obtain a speed of from 150 to 300 H. and D. (ferrous oxalate) almost all these condi-

tions are reversed. Thus the plates have distinct—i.e., easily measurable—tendencies to fog in development. They have a comparatively coarse grain, and hence density is only obtained on prolonged development, as, the grains being large, the developer can with difficulty reduce to metallic silver the entire granule. The rapid plate has a long scale of gradation in its characteristic curve, and consequently tends to give soft results, with a wide range of tone, rather than contrasty pictures; and finally, reversal takes place fairly soon after the maximum normal exposure has been received.

The latitude of a plate being directly proportional to its opacity, a very rapid plate should, theoretically, possess very little. In practice, however, as I hope to show later on, an extraordinary amount of latitude is possessed by many makes of very fast plates, although of course we have a wider margin with slow varieties.

Gelatine as a Factor in Speed.

The chemistry of the very fast plate, so far as it is known, is of great interest, and is briefly as follows:—

The emulsion consists of granules of silver bromide and silver iodide imbedded in gelatine, the bromide being in the greater proportion. It is questionable whether any interaction takes place between the iodide and the gelatine, but a recognised compound of silver-gelatino-bromide is formed. A certain quantity of ammonia is employed in the emulsification, and silver bromide is soluble in this, so that the gelatine surrounding the granules of silver haloids is partially saturated with an ammoniacal solution of silver bromide. Hence the gelatine itself becomes sensitised, and owing to the sensitiveness thus acquired it at once becomes a factor in the production of fog during development.

The faster the plate, the more readily is bromide absorbed by the gelatine. This may be taken as a general axiom. And until some fresh methods of manufacture are devised the rapid plate will always

have greater tendencies than the slow plate to (i.) large grain, (ii.) fogging of the gelatine surrounding the granules, (iii.) steady gradation, and (iv.) lack of density in the deep shadows.

Speed and Colour-Sensitiveness.

It is well known that a slow plate is only sensitive to violet and blue rays of light; thus, very slow emulsions, such as those containing silver chloride and bromide, are chiefly affected by the region of the spectrum lying between the H. and F. Fraunhofer lines. As, however, the emulsion becomes treated with iodide, and receives more and more digestion, or assimilation of pseudo-digestion I had perhaps better say, the sensitiveness extends further and further through the bluish-green, green and yellow, and finally on through the orange and red even into the invisible infra-red. I would like it to be understood now that I am speaking only of what may be termed the *normal* exposures; with ridiculously long over-exposure even a slow plate can be made to appear sensitive to green and orange rays of light, but the portion of it exposed to the blue region will by this time have suffered reversal.

It will be clear from this that a very fast plate must, in order to give it its full chance, so to speak, be treated with all the reverence due to an orthochromatic plate. I have endeavoured to show this sensitiveness to the whole spectrum graphically by means of photographic negatives taken on a slow plate (150 H. and D.), and a fast plate (400 H. and D.), of the spectrum of the arc light, coloured spectrograph first. You will see by the slide shown on the screen two negatives of the spectrum as already stated; the upper one is on the slow plate, the lower one on the rapid plate. In the latter you will observe that the O on the scale is visible, and the O position is practically at the end of the visible red. The top spectrograph is one showing a few lines; thus the D line is situated at 4 on the scale, and it is just visible even in the rapid plate. Although compared with its sensitiveness to violet and ultra-violet light the rapid plate is very slightly affected by red, it is obvious that continued exposure to direct rays from a dark-room lamp is quite sufficient to fog the plate, and we shall therefore return to this subject again a little later on.

Meantime, I think it will be interesting to see the effect of sunlight during varying conditions of weather on a plate sensitive to the whole spectrum, as by estimating the density of successive portions of the negative curves can be plotted out showing the varying quantities of red and green light in fine weather, rain, direct sunshine, etc. These variations, although slight, have nevertheless to be sometimes considered in making an exposure with a plate influenced by them.

Having now in the view the chief characteristics, good and bad, of a rapid emulsion, we are in a position to consider the methods of treatment which will lead to the best results.

Darkroom Illumination.

The red-sensitiveness of rapid plates being borne in mind, it is always a wise precaution to employ a red lamp in the dark-room instead of a yellow or orange illumination, and if red glass be used it should be examined carefully by means of a pocket spectro-scope to see that no green light is transmitted, as is so often the case with so-called ruby glass. The man who works hard, and therefore spends a good deal of time in the dark-room, will require an illumination as brilliant as can be obtained consistent with safety, and for that purpose I can confidently recommend the following mixture for use in tank-lamps—the ideal lamps for lighting the dark-room:—

Tartrazine	3 parts.
Titan scarlet	2 parts.

This mixture is dissolved in water varying in quantity according to the thickness of the cell. The colour should be such that a little pure yellow and orange passes through the solution, but the maximum luminosity is in the pure red beyond C.

Another very good dye for tank lamps, which passes more orange and yellow, and therefore gives a more pleasant illumination, as far as the eye is concerned, is mandarin orange, and I think Messrs. Chas. Zimmerman supply this for the purpose. Care has to be taken with this dye that it is used in sufficient quantity, as too weak a solution is quite useless.

If the dark-slides are not loaded in the dark, it is a safeguard to turn one's back on the red light and thus shield the plates from the direct rays. It will always be found that the greatest danger of fogging a plate by light is in the manipulations which precede development, and not those which follow it.

A Black Backing for a Rapid Plate.

The question of backing is of considerable importance with rapid plates, as halation is readily produced with them. It is obvious that a plate which lacks opacity owing to the size of the granules of silver bromide will give halation more readily than an opaque plate; but even when a fast plate appears just as opaque to the eye as a medium-speed one, there is still the possibility of its being slightly more translucent. The backing applied must not be of the sienna type, as in a long exposure, especially on a coloured subject, the reflected red rays, which of course should not exist theoretically, will affect

the plate; an Indian Ink backing, or any of the forms of dead-black media, is preferable, or similarly a deep red. The backing should be allowed to dry thoroughly before the plates are either put into the dark-slides or wrapped up for storage, as damp is one of the most formidable antagonists to the keeping qualities (in stock) of a quick emulsion.

Speed Numbers of Rapid Plates.

A good deal might be said with regard to exposure. Exposure depends upon speed, and speed is usually ascertained by the manufacturer, and the manufacturer is not always believed. It is supposed by a great many that a manufacturer claims a high speed for a plate because it brings him business, but this is entirely a fallacy. Putting a wrong speed number on a box of plates conveys a wrong idea of their speed to the user, who merely makes an error in the exposure, and is consequently dissatisfied with the results.

What I should more particularly like to draw attention to is the method in which plate speeds should be obtained by the manufacturer, and the way in which the numbers given should be interpreted by the user. The most reliable means of determining the speed of a plate is that devised by Messrs. Hürter and Driffield, but they chose as the standard developer ferrous oxalate—a reducer which is only used very rarely by the present-day photographer, as it is entirely unsuited to modern rapid plates. The use, therefore, of ferrous oxalate, whilst being almost necessary in the case of accurate research or laboratory work, is not advisable when determining the speed for the photographer, as the speed, so-called, of a plate is almost double with pyrogallol or metol that it is with ferrous oxalate. Pyrogallol, with ammonia and with sodium carbonate and metol-hydroquinone, are the developers chiefly used by photographers for the majority of their work, and therefore the speed number referring to such developers, which is approximately 9.5ths the ferrous oxalate number, should unquestionably be given.

Bromide and Speed Numbers.

Another point is the use of bromide. Potassium bromide in the developer slightly destroys the latent image, but it does so quite impartially, hence the shadows suffer, comparatively, more than the high-lights, as the same amount of sub-bromide is reconverted in each. But bromide is used in practically all developers, and it should therefore be used in the solution employed to determine the speed number of a plate. I am again referring to the "practical" speed number, and not to the number obtained only for scientific guidance.

The best guide for the practical man is to give him a speed number which can be taken as applied to the developer he is likely to use in his work; and if speed numbers were obtained by the Hürter and Driffield methods, using a pyro-soda or metol-hydroquinone developer with an average quantity of bromide, and some simple tables or actinometer arranged to calculate the exposure from such numbers, the most accurate practical results would, I feel sure, be obtained.

Gradation Rendering.

The use of extremely rapid plates for purposes where a very wide range of tone is required is perfectly legitimate, and soft negatives—the blacks of which are not opaque to block the detail—are readily obtainable; not only because the gradation obtainable is steady and even, but also because the extra speed enables the half-tones to receive longer comparative exposure, as one can afford the time, even in the studio.

In the slides I will ask the lanternist to put on the screen, we see H. and D. strips, the characteristic curves of three plates, slow, ideal, and rapid, and if we take any ordinate P, P, P., and compare on this line the amount of density obtainable for the same exposure, we find the slow gives the greater and the rapid the less density. This is, however, true only after a good exposure has been received, and in the next slide we see the practical comparisons. The slow plate gives the less density, the rapid plate the more, up to a certain point in the exposure, and after this point the rapid plate develops up soft and not too opaque, while the slow plate gives great density and consequent harshness.

Pyro The Developer for Rapid Plates.

The Development of Rapid Plates.

In considering the development of very rapid plates, it is necessary to bear in mind the tendency to fog, the coarseness of the grain, the difficulty (comparative) with which density is obtained in the high-lights owing to premature reversal (the word "premature" is again used comparatively). The development of a plate is worked by means of three levers, if we may call them such. The density giver or developing reducer, the accelerator or gradation producer, and the restrainer, which at the same time ensures cleanliness. The restrainer, which is of course usually bromide, is a lever which is apt to be wrongly worked, for the reason that unless added at the commencement of development it does not partially cut out the latent image, i.e., practically reduce the effect of the exposure—when added after the image has once become visible it merely slows development, thus enabling the ingredients of the latter to be modified before too much danger is done.

The best negatives on rapid plates are therefore obtained by considering what substances best fulfil the conditions imposed upon them. Such developers as metol or metol-hydroquinone are hardly divisible; amidol similarly is not worthy of consideration; aikonon, if used carefully, will give good results; but after a considerable amount of experimenting, pyrogallol has proved the most valuable all-round reducing agent. The pyro-ammonia developer is good, because so much bromide may be employed with it; the pyro-soda developer is good because, besides its clean-working properties, it enables one to control the development so easily, and to produce any class of negative whatever at will.

Restrainers for Developers of Rapid Plates.

The photographer who aims at artistic results finds it necessary to modify a normal developer in order to produce a sufficiently soft result with plates of medium rapidity; but when using rapid plates the gradation comes of itself, and our aim is more especially to produce sufficient vigour in the high-lights. Moreover, an extremely fast plate is, or should be, used on occasions when the circumstances of the exposure render it likely that every available bit of speed will be required, and therefore if we can possibly manage to work without bromide the full advantage of rapidity may be obtained.

A developer which is unequalled for use with such plates as the Ford "Monarch," the Cadett "Lightning," the Barnet "Red Seal," the Gem "Salon," etc., is one in which bromide is replaced by sodium citrate and sodium sulphite, which ensures cleanliness without reducing the effective exposure. It is a pyro-soda developer, and the reducing solution is made by dissolving 30 grammes of pyrogallol, 25 grammes of citric acid, and 150 grammes of sodium sulphite in 1,000 ccs. of water; the accelerator is merely a 25 per cent. solution of sodium carbonate. The great charm about this developer is the evenness of gradation which it gives, and negatives with a very wide range of tone are readily obtainable with it, in which the deepest shadows can be printed through.

Summer Dangers—Over Exposure and Warm Developer.

One of the chief difficulties, however, with plates of high speed is their exposure. The easiest mistake to make is to over-expose, and as the characteristic curve of the emulsion evidences a tendency for reversal at an early stage of over-exposure, the constituents of the developer are best arranged so as to give abnormal density; the abnormal density giving power, of course neutralises the flatness of the negative, or rather its tendency for flatness.

Development in summer is a subject which deserves special consideration. We have seen that the rapid plate has a tendency to give fog, especially if forced at all, during development. But the

fog-producing factor is enormously increased with a rise of temperature, the increase being unfortunately very unreasonable in : : " And the faster the plate the more unreasonable still is this proportion, so that it is essential, in order to treat the plates fairly, to keep not only solutions, but dishes, and the dark-room at as cool a temperature as possible.

Fixing Precautions.

A fairly weak fixing solution is required in order to avoid the partial solution of the least-exposed parts of the picture, and in order to prevent development from proceeding after removal of the plate from the developer, a small amount of acidity is desirable in the fixing bath. A very satisfactory solution will be obtained by dissolving 5 oz. of sodium thiosulphate and 60 grs. of acetone sulphite in a pint of water. If speed has been obtained by long digestion of the emulsion, and a tendency for frilling produced in consequence, the introduction of a small quantity of alum into the fixing bath may be necessary.

After-Treatment of Rapid Plates.

It is hardly my duty to-night to give practical suggestions for everyday work to members of the Photographic Convention, and I have therefore said little about development; but I would like to say a few words in connection with the intensification of over-exposed and flat negatives. The grain of the negative being large already, we require a method of intensification which will give us the greatest possible strengthening of the image concurrent with the least increase possible of the size of the granules (rehalogenising with subsequent partial reduction is therefore undesirable). Moreover, it is generally necessary to clear the unexposed and least-exposed portions of the negative previously to intensification in order to clear these parts from development fog. I have found that it is possible to substitute one operation for the two by simply employing an intensifier which will reduce in density the least-exposed parts of the negative, whilst it adds to the density of the more exposed parts. Such a result can be produced by bleaching the negative in a solution of mercuric chloride and ammonium chloride, with subsequent treatment with a re-blackening agent which readily dissolves Ag Cl, such as ammonium or sodium thiosulphate. Beyond these remarks, I have little else to say. On an occasion like the present, when the reading of a paper has been preceded by a long and fatiguing excursion on a very warm day, a lengthy mass of information on a strictly technical subject is not diplomatic on the part of its reader. But the little I have said will, I trust, have proved interesting, being founded, as it is, on the results of a long experience with the preparation and use of extremely rapid plates.

T. THORNE BAKER.

The following discussion ensued:—

Mr. C. H. Bothamley expressed his pleasure that a paper so full of practical suggestion had been brought before the Convention, and described the reasons given by one of the oldest conventioners, the late Mr. Frederick York, for preferring a plate with thin films, well backed, and of only medium sensitiveness, for general work. In many cases of architectural interiors, where the exposures were, for the most part, too short to give full detail in the shadows, Mr. Bothamley had found the great value of the same class of plate.

Professor J. Alfred Scott, M.D., said that in his own photography, which was entirely for lecture-illustration, by means of lantern slides, he had found extremely rapid plates unsatisfactory. There was inability to fog, thinness of image, with large grain, which was increased by intensification, and, of course, greatly exaggerated on the screen. Many of his subjects were zoological—ochreous-coloured animals, in yellowish surroundings—and he got the most satisfactory results by using plates of medium sensitiveness, and developing until the negative was exceedingly dense.

Mr. H. Snowden Ward said that he thought that examination of the safe-light by spectroscopy would not appeal to the ordinary working photographer, who might better test his light by exposing the sensitive surface to be worked with it, for the longest time and at the shortest distance that would occur in practice, with part of the surface shielded from the light, so that subsequent development would show whether the unexposed part was fogged. He hoped that, perhaps for the next Convention, Mr. Thorne Baker would amplify his suggestions re those combinations of development and intensification whereby the advantages of the very rapid plate and the slow plate might to some extent be secured at the same time, and specially commended the remarks on the effect of temperature upon development.

Mr. F. A. Bridge supported Mr. Ward's recommendation of test by exposure rather than by spectroscopy, and mentioned several classes of work for which the thin plate, well backed, and not of excessive sensitiveness, was decidedly the best. With extreme contrasts, and also when sufficient exposure was impossible (as in underground workings), it was the best plate one could use. But—and this was very important—it must be a plate that would stand "playing with" in development.

Mr. Hedley M. Smith, of Paris, said he thought that the paper should have been entitled "The Disadvantages of Extremely Rapid Plates," for they had more disadvantages than virtues. In his own work, and in dealing with the work of thousands of amateurs, he had found that an emulsion of medium sensitiveness was almost invariably the best. Extreme rapidity was a real advantage only in a very few cases, and then only in most competent hands.

Professor John Joly, F.R.S. (president), said that extreme rapidity had been of great value in some recent scientific work. The views of the corona of the unclipped sun, which were brought out by successive processes of intensification on plates exposed through deep colour-screens transmitting red, were a case in point. Another was the report from America that the "canals" of Mars had been photographed, and if this were confirmed, it would make a new "record" for the photographic method of observation. Hitherto, though the plate, by its cumulative action, excelled the eye in recording very faint luminosities, the eye had excelled the plate in detecting faint differences of luminosity. If the Martian "canals" had been photographed, the plate would have recorded what only a few highly-trained eyes (as those of Schiaparelli) had been able to see.

A curious question in relation to sensitive plates arose from the recent demonstration of the universal bombardment of electrons. It seemed impossible to escape from this bombardment, which penetrated even boxes of thick lead, and which had the property of ionising the air and all bodies with which it came in contact. As this ionisation affected plates in the same way as light did, it seemed marvellous that all extremely sensitive plates were not spontaneously fogged. It might be because the fading of the latent image (which had been proved to occur) was as rapid as the ionising, but the point was an interesting one, and worthy of investigation.

In reply, Mr. T. Thorne Baker dealt with several of the questions raised. He recommended, in the case of the subjects mentioned by Dr. Scott, that the development of the extremely rapid plates should be incomplete, and be followed by intensification with mercury and hypo, to secure density without very large grains.

BURROUGHS WELLCOME AND CO.'S QUARTER CENTURY COMMEMORATION.

THE Wellcome Club and Institute at Dartford, Kent, was a scene of great activity and brilliancy on Saturday last. The occasion was the visit of the President, Council, and Members of the Society of Chemical Industry of the British Empire and America, and a fête commemorating a quarter century's work of the firm of Burroughs Wellcome and Co. A most elaborate programme had been arranged, including a display by the private fire brigade of the Institute, aquatic sports, a luncheon to over two thousand guests and employees in a huge marquee, athletic sports, maypole dances, dinner in another marquee, fireworks and illuminations, and an open-air concert.

The weather was propitious, and the splendidly organised arrangements went without a hitch, thus speaking well for the *esprit de corps* apparent on every side in this model firm, which can be likened more to a great happy family, numbering over thirteen hundred, than to an ordinary business house. At the luncheon many guests distinguished in the world of pharmacy and medicine were present. Mr. H. S. Wellcome presided, and the toasts were received with great enthusiasm. Congratulatory telegrams were received during the morning from branches at Berlin, Montreal, Shanghai, Calcutta, Amsterdam, New York, Brussels, Switzerland, Vienna, Sydney, the West Indies, and Milan, and after luncheon Mr. Wellcome presented the cup of the Wholesale Chemists and Druggists Cricket Championship to the Wellcome Cricket Club, who had won it five years in succession. In the staff club house of the Institute an exhibition of historic medicine cases proved of great interest. They included one of the "Tabloid" medicine chests carried through "Darkest Africa" by the late Sir H. M. Stanley; one of the medicine cases specially designed for and supplied to the hospital ship "Maine"; also the saddle-bag medicine cases used by Dr. J. W. B. Wellcome, in pioneer days of Minnesota and Dakota, during the great Sioux Indian wars, etc., etc.

In the gymnasium an exhibition of photographs was on view. This exhibition, organised by the photographic club of the Wellcome Club and Institute, consisted entirely of pictures by club members and employees, and the work was of a high average. Egyptian and Soudanese photographs, photographs of St. Louis Exposition, and some typical pioneer Western American and Mexican habitations and views were exhibited by Mr. Henry S. Wellcome, and the winning photographs at the Chemists' Exhibitions 1903, 1904, and 1905:—The Bread Winners—1st prize, 1903, H. W. Lane; Early Morning in a Pine Wood—1st Prize, 1904, E. F. Harrison; The Artists' Valley—1st prize, 1905, H. W. Lane, were also shown. The club's permanent collection, consisting of pictures purchased by Mr. Wellcome from previous photographic exhibitions and presented to the club to form a representative show, included several fine pictures by H. W. Lane, W. H. Fawkes, H. W. Gray, E. F. Harrison, and H. H. Crosbie.

An arts and crafts exhibition, consisting entirely of work by club members and employees, was also interesting. It included over 300 entries in the following classes:—Needlework, Fancy Work, Model Carving, Fretwork, Poker Work, Machinery, Vegetables, Flowers, Fruit, Cookery, Painting, Drawing, Table Decoration, Scientific apparatus, etc., etc.

Altogether, the firm of Burroughs Wellcome and Co. can be congratulated on a most successful commemoration function, and we look forward to seeing this house of original ideas and sound business methods, go on flourishing and repeating Saturday's entertainment on even a larger scale every succeeding quarter of a century with that regularity and despatch which characterises every other phase of its organisation.

PHOTOGRAPHS OF ROYALTY.

A WRITER in the "Book and News Trades' Gazette" discusses at some length the relative popularity of Royalty and stage favourites as subjects for picture postcards. He says:—"The portrait postcard claims much attention both from publishers and retailers, but the latter are, I think, inclined to give too much of their attention to one description of portrait postcards. I refer to the stage celebrity portrait, but recognise that these are very greatly in demand, and therefore merit some amount of attention, and many will, perhaps think that it is impossible to give too much heed to such cards. They are to a certain extent right, but there is no reason why other portrait cards should be neglected. In their anxiety to supply the extraordinary demand for pictures of actors and actresses many retailers have ignored the portraits of members of the English Royal family. Taking Miss Marie Studholme as a representative for stage celebrities and King Edward VII. for the Royal family, I make bold to say that, if retailers gave equal prominence to the two portraits in their window displays, the bigger demand would be for the photograph of the King. Every true Britisher respects him—in fact, I might say loves him—while foreigners and colonialists would always welcome the opportunity of purchasing a portrait of the world's greatest Sovereign. Pictures of prominent actors and actresses, while only appealing to a section of the public, have sold in unthought-of numbers, so that it is hard to imagine how big would be the demand for a picture of the King of England, who can also lay claim to being the King of Diplomats and the King of Sportsmen, if his portrait was well shown by all retailers of pictorial postcards. The Queen would not be one bit less popular, while portraits of the other members of the Royal family would also sell well. But there is no need to confine these remarks to members of the English Royal family; a ready sale could be found for portraits of all the crowned heads of Europe if retailers would only see that they are properly shown. I make the statement knowing full well that those newsgents and stationers who have given such cards a trial have been more than pleased with the result."

NATIONAL PORTRAIT GALLERY.—In their annual report the trustees of the National Portrait Gallery remark that much of the increased popularity which has been gained for the National Portrait Gallery during the last few years has been to a great extent due to the noble series of portraits painted and presented by Mr. Watts, and "they wish to place on record their sense of the debt owed by them and this country to their late distinguished colleague for his public spirit and generosity." The pressure on the existing wall-space in the galleries suitable for the hanging of pictures, and the difficulties in maintaining the historical and chronological arrangement of the collection continue to increase. The trustees have been in communication with the Army Council as to the possibility of some portion of the site now occupied by St. George's Barracks becoming available for an extension of the gallery; but up to the present date the trustees do not find themselves in a position to think that there is any immediate prospect of the much-needed extension to the National Portrait Gallery taking place.

THE R.P.S. AFFILIATION.—The judges have made the following awards in the third Lantern Slide Competition:—Plaque, E. Seymour (Watford C.I.C.) for his slide entitled "Currants"; plaque, G. J. T. Walford (Southend-on-Sea P.S.) for his slide entitled "A Norman Triforium"; plaque, J. Walker (Birkenhead P.A.) for his slide entitled "After a Shower"; first certificate, South London P.S. (2.65 points); second, Southampton C.C. (1.95); third, North Middlesex P.S. (1.91). The executive committee has selected for circulation among the affiliated societies a number of slides from those sent in for competition.

Photo-Mechanical Notes.

"True Scale" Photo-Lithography.

A good deal of attention is being paid at present to reproductions of same size from originals in black and white from the paper drawings themselves, as, for example, maps and plans or engineers' drawings. Most of the new Ordnance maps are produced in this way, the original map being drawn on Whatman paper in quite opaque ink. This drawing is then placed in contact with a zinc plate, sensitised with a film of bichromated fish glue, and exposed from ten minutes to four hours, according to the light. This plate is then developed, giving a negative image on the zinc plate, the ground of the drawing being represented by insoluble fish glue, and the lines by bare zinc. After drying, the plate is inked over with a greasy ink, and then placed in very weak hydrochloric acid, and rubbed gently with a wad of cotton wool; this brings away the insoluble fish glue and the ink on top, but does not remove the ink from the lines, thus giving the desired positive ready for printing in the usual lithographic way.

The process outlined above has been patented by Conductor Andyke, of the Government of India Survey, and a full account of the process is to be found in the Report of the Survey of India Office for 1899-1900, page 26 of the Appendix.

Recently Messrs. Klimsch, of Frankfort-on-the-Main, have patented a modification of the above process (3,608 of 1904), which consists in treating the bare lines of the zinc after the negative image is obtained by some chemical to remove what they term the "alteration product," which they say is formed when bichromated fish glue is placed in contact with metal, even though the glue is not rendered insoluble.

However, there does not seem to be any trouble in working the process without this modification, provided a suitable ink is used, and is allowed to remain on the metal long enough before development is attempted. Such an ink can be simply made by taking bitumen four parts by weight, lithographic printing ink in sticks one part, and dissolving in benzole until completely homogeneous, and then thinning with turpentine to the requisite consistency for rolling on the plate. The time it should be allowed to remain on, before development, is at least four hours to be certain of getting good results when developing.

If, however, it is desired to develop at once, then, after the fish-glue negative image is on the zinc, it should be dried, and the plate plunged for an instant in iron chloride solution at 5 deg. Réaumur. The plate must not be left in longer than just sufficient to blacken the bare zinc lines, otherwise the iron stains the fish glue, and it is difficult to rub it away. Or, instead of iron, a very weak solution of tin chloride may be used, say one grain to the ounce of water. Considerable knack is required in using either of these solutions, so that if the time can be spared it is simpler not to use them, but merely to allow the inked-up plate to rest over night, or for some hours.

PROCESS in India obtains extremely good representation in the "Empress" magazine, edited by A. J. Parker, and printed by Messrs. Thacker, Spink, and Co., of Calcutta. A copy which just reaches our table shows the very full half-tone illustration adopted in the production of the magazine. Some half-dozen pages are occupied by pictures of the recent earthquake in Northern India, and the final effect of photography, block-making, and printing is such as many a journal produced in London would be glad to equal. We are interested in learning that the "Empress" has been using process blocks since 1898, and that all the photo-mechanical work is done in the office by a native and Eurasian staff.

New Materials.

The Barnet Roll Film. Made by Elliott and Sons, Limited, Barnet, Herts.

With the desire to make the roll films of their manufacture completely responsive to the demands of the great army of photographers who pin their faith to this form of sensitive material, Messrs. Elliott have now issued a revised edition of the film, in which are embodied the two very distinct advantages of orthochromatism and flatness in the finished state. The latter quality, be it observed, refers to the superficial contour of the film, not to the character of the negatives, which, in our experience, are endowed with desirable brilliancy and vigour. No user of the film can fail to appreciate the gain in ease of manipulation which a flat film confers in comparison with one that curls. The added iso properties are probably overlooked altogether by a large proportion of those who go forth photographing and to photograph; but the minority, who have proved the benefits of a film sensitised for the green and yellow, will thank Messrs. Elliott for this gratuitous boon. We need not say more, except that in its other properties the new Barnet film sustains us in the good opinion we had of its progenitor, and we note its appearance as another instance of the watchfulness exercised in the production of the various "Barnet" manufactures. For the convenience of our scientific friends we give sensitometric measurements by C. E. Kenneth Mees, B.Sc.:—

Inertia (H. and D., pyro-soda), .289.

$\gamma \propto$ (density-giving power), 2.68.

K (velocity constant of development with standard ferrous oxalate), .060.

Opacity (to blue light—an index to latitude), 17.

t_f (time of development for standard gradation of 1), $7\frac{1}{2}$ minutes.

Colour ratio $\frac{\text{Blue sensitiveness}}{\text{Yellow sensitiveness}} = 11.2$

The roll film is issued in the usual sizes at the standard price

AN interesting little catalogue of photo jewellery has been sent us by Messrs. F. Helmrich and Co., Wholesale and Export Jewellery and Fancy Goods Merchants, of 37, Walbrook, London, E.C. Screw top photo pendants, miniature rims with velvet backs, lockets, brooches, and necklets, in great variety are listed in various styles and finish, rolled gold, silver, or nine carat gold. Judging from the illustrations with which the catalogue is embellished, some very chaste designs in this popular form of trinket are to be obtained from Messrs. Helmrich at very reasonable prices. In addition to these metal frames, etc., a selection of excellent wood and ornamental photo frames are illustrated also at low figures, while postcard albums and series of picture postcards are likewise included. Every photographer and dealer interested in these remunerative side lines should send for a copy of this catalogue, which will be sent free from the above address.

ROYAL PHOTOGRAPHIC SOCIETY.—The Council has appointed as a committee to abstract from English and foreign journals and to report upon materials and apparatus sent to the "Journal" for review:—(Abstracts) Messrs. T. Thorne Baker, F.C.S., George E. Brown, F.I.C., A. J. Bull, E. J. Denney, F.I.C., A. Haddon, H. Holcroft, M.A., F.C.S., C. E. K. Mees, B.Sc., A. J. Newton, H. H. O'Farrell, Welborne Piper, A.R.I.B.A., Dr. Prevost, Messrs. F. F. Renwick, E. A. Robins, S. E. Sheppard, B.Sc., E. J. Wali, and Major-General J. Waterhouse, I.A. (Reviews) Messrs. S. D. Chalmers, M.A., C. E. K. Mees, B.Sc., A. J. Newton, and S. E. Sheppard, B.Sc.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes."

The following applications for patents were made between July 3 and July 8:—

PRINTING FRAMES.—No. 13,817. Improvements in photographic printing frames. John Lewis, 24, Temple Row, Birmingham.

BLOCKING OUT.—No. 13,846. Improvements in the method of blocking out certain parts of photographs, drawings, etc. Cecil Haldy and Taylor Garnett, Evans, and Co., 51, Deansgate Arcade, Manchester.

STEREOSCOPY.—No. 13,862. A stereoscopic magic lantern. Charles Hartley Clements, 8, Euston Square, London.

COLOUR PROCESS.—No. 14,023. Improved chemical colour printing process. Peter Oscar Serck, 12, Charlwood Race, Belgrave Road, London.

ENLARGING.—No. 14,052. An improved stand for use in bromide printing, and for enlarging, reducing, or copying photographs. Arthur Jas. Lambert and Charles Henry Land, 8, Quality Court, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

TRIPOD.—No. 18,718, 1904. The full patent specification of a tripod recently reviewed in our pages is now published. The claims are for:—1. The improved means for connecting the legs to the tripod head, consisting of swivel blocks connected at preferably equal distances apart near the outer edge of the underside of the tripod head, links connecting the upper ends of the legs to the swivel blocks and head, and tightening screws for holding the legs, links, and blocks in the required position. 2. The combination with a tripod leg of a swivel point that may be fixed in a vertical or an approximately vertical position, with the leg in a position more or less inclined. 3. The combination with tripod legs, links, and swivel blocks of extension bars such as *k* and block *x* for the purpose of occasional extension. 4. The general

combination and arrangement of parts constituting means for enabling a tripod head to be placed and fixed in either a horizontal position or a vertical position, or at any angle between a horizontal and a vertical position. The construction of the chief novelty in the tripod, the swivel block connecting each leg to the tripod head, will be clear from the figure. William Butler, 20, Crosby Road, Birkdale, Southport.

CELLULOID.—No. 11,512, 1905. Protection is claimed for a process of preparing celluloid by dissolving borneol in a solvent for nitro-

cellulose, mixing intimately the dissolved borneol with the nitro cellulose, and eliminating the solvent after the mixture has become homogeneous. Auguste Behal, 4, Avenue de l'Observatoire Paris.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—

PHOTOGRAPHIC MOUNT.—No. 12,273, 1905. Cheney.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
22.....	Hull Photographic Society	Outing to Stamford Bridge.
22.....	Birmingham Photo. Society. ...	Half-day Excursion to Sutton Park.
22.....	Cricklewood Photo. Society	Trip to Chalfont St. Peter's.
22.....	South London Photo. Society....	Outing to Chingford Marshes.
23.....	Wallasey Amat. Photo. Soc.....	"Lenses." Mr. W. Hayes.
21.....	Everton Camera Club.....	Evening Outing to Fazakerley.
25.....	Birmingham Photo. Society.....	{ Exhibition of Pictures taken on Excursion to the River Thames.
25.....	Manchester Amat. Photo. Soc. ...	{ "Woodland Photography." Mr. J. D. Berwick.
26.....	Everton Camera Club	Evening Outing to Fazakerley.
26.....	North Middlesex Photo. Soc....	{ "Further Words on Toning Bromide Papers." Mr. A. G. Lawson.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the annual meeting of the L. and P. P. A., on June 29, the following were elected officers for the ensuing year:—Trustees—A. Haddon, T. E. Freshwater. Committee—R. Beckett, S. H. Fry, T. K. Grant, E. Human, R. J. Kindon, D. W. Hart, J. S. Teape, J. E. Ellam. Hon. curator and lanternist—E. T. Wright. Hon. librarian—W. J. Marshall. Hon. secretary and treasurer—H. C. Rapson, 13, Shaftesbury Road, Hornsey Rise, N., to whom all communications should be addressed. Meetings are held every Thursday evening at 8 o'clock at the White Swan, Tudor Street (room open at 7 o'clock). During July and August all meetings are open for general discussion.

ABERDEEN PHOTOGRAPHIC ASSOCIATION.—The annual excursion of this association took place on Saturday last. There was a large muster of the members and their friends, and the party journeyed by train to Stonehaven.

SOUTHAMPTON CAMERA CLUB.—The members of this society to the number of about fifty, enjoyed a repetition of last season's launch trip up the Beaulieu River. At the ordinary meeting of the club at headquarters on Monday evening, Mr. C. D. Kay gave a demonstration of the carbon process. Mr. S. G. Kimber, the club secretary, expounded the beauties and advantages of the platinum process.

THE OPTICAL CONVENTION.—We owe an apology to our readers for our omission to print the discussion of Mr. Rosenhain's paper on "Possible Directions of Progress in the Production of Optical Glass," but an authorised text of the discussion proves unobtainable from the Papers Committee, and we therefore refer our readers interested in the subject to the official report of the Convention, which will doubtless be issued in due course.

A NEW PHOTOGRAPHIC FLASH-LIGHT.—The studio flash-light of a French photographer consists of a large parabolic reflector of aluminium, with a series of incandescent lamps around its edge, and in the centre an arc lamp with three carbons—one fixed and two movable. The small lamps enable the photographer to pose the subject. When this is done, pressure on a rubber bulb draws the movable carbons across the fixed one, producing an arc for the fiftieth of a second, and closing a circuit which energises an electro magnet pulling the carbons away. The brilliant flash is said to give life-like portraits.

News and Notes.

INDUSTRIAL ALCOHOL.—In accordance with the recent promise of the Chancellor of the Exchequer, a memorandum explanatory of the Revenue Bill has been issued by the Treasury. The main object of the Bill is to give legal effect to the recommendations of the Departmental Committee appointed last year by the Chancellor of the Exchequer to consider questions relating to the use of spirits for industrial purposes. In order to lessen the cost of using spirits for industrial purposes in this country, it is proposed—1. That an allowance should be given to cover the cost of the Excise restrictions in respect of all spirit used for industrial purposes, whether it is methylated spirit or pure spirit, used under Section 8 of the Finance Act, 1902. 2. That the first grade of methylated spirit need not be so completely denatured as it is at present, and that the minimum amount of wood naphtha required for methylation should be reduced by one-half. 3. That the cost of the necessary supervision required in the use of spirits under Section 8 of the Finance Act, 1902, should not fall upon the manufacturer, except in special cases; and that foreign methylic alcohol used under Section 8 of the Finance Act, 1902, should no longer be subject to the surtax even though it be purified so as to be potable. It is also proposed that the restrictions on the retail sale of the second grade of methylated spirit should be somewhat relaxed.

"TABLOID" PYRO-METOL PRIZE COMPETITION.—The prizes offered by Burroughs, Wellcome, and Co. for negatives developed with "Tabloid" Pyro-Metol Developer have been awarded as follows:—1st prize, S. G. Kimber, Southampton, £5 5s., for "Unjil the Daybreak"; 2nd prize, Clarence Ponting, Scarborough, £3 3s., for "Roses"; 3rd prize, Mrs. G. A. Barton, Birmingham, £2 2s., for "Bottin." Works submitted by the following competitors are highly commended, and Burroughs, Wellcome, and Co. have purchased the negatives of their respective pictures:—Adolphe Abrahams, Cambridge, "Throwing the Hammer" and "The Hurdle Race"; Geo. L. A. Blair, Paisley, "Sunset"; F. Cecil Cobb, Margate, "Look Out"; J. MacLennan, Aberdeen, N.B., "The Harbour, Aberdeen"; A. H. Ross, Dundee, "Blossom"; A. F. Morrow, Tooting, "In Norway"; Clarence Ponting, Scarborough (in addition to "Roses" which wins a prize), "Reflections."

THE FUTURE OF THE CAMERA CLUB.—At the extraordinary general meeting of the Camera Club Company which, as announced in our last, was held on Monday, the existence of the Camera Club as a separate entity was practically doomed, for it was decided, unanimously, to amalgamate with the Blenheim Club, of St. James's Square. Some interesting details were given as to the Camera Club; here are, it appears, 212 town members and 193 country members, and of this 400 odd only about 50 were found who took sufficient interest in the existence of the club to turn up to consider the proposals which had been put forward for consideration. In the first place, it was announced that the second suggestion "to make a whip, and increase the amount of subscriptions for the year 1906, and possibly subsequent years," was withdrawn, the reason being that already eight resignations had been received, apparently on account of this suggestion, since the circular had been sent out. It appears that there is still enough money available to carry the club on till the end of August, and that, if everything is sold up, all liabilities will be discharged. The journal, in any case, is to be given up as not proving remunerative. The Blenheim Club has a membership of 1,600 and they are, so far as the negotiations have proceeded, prepared to absorb the Camera Club without entrance

fee, provided at least 300 members of the latter club are willing to join. The annual subscription to the Blenheim is seven guineas; but if the 300 members will join they are to be admitted for five guineas, at any rate for the first year, if they pay the subscription in advance. A committee was empowered to issue another circular to all the members, laying before them the proposition, and asking for support. We think it is extremely unlikely that the general body of Camera Club members will dissent, considering that the photographic character will practically disappear; although it was stated that the Blenheim will build a studio and fit up dark rooms, to the former of which, by-the-by, ladies would not be admitted. Another point is that the distance limit for town and country members for the Blenheim is much greater than for the Camera Club, and, therefore, this would mean an increase of subscription for many. Presumably so far the negotiations have been between the committees of the two clubs, and it remains to be seen whether the rank and file of the members of the Blenheim will endorse their committee's action.

Commercial & Legal Intelligence

THE CROOKE-IRVING CASE.—An important case came before the Court of Session, Edinburgh, at the end of last month, and was reported at length in "The Scotsman" of June 28 and 29. Lord Ardwall reserved judgment, and our report of the case should have appeared last week, had not great demands upon our space crowded it out. The action was brought by Mr. William Crooke, the well-known Edinburgh photographer, against the Scots Pictorial Publishing Company for infringement of his copyright in a portrait of Sir Henry Irving. Mr. Crooke claimed damages £2,000 and delivery of all copies made, or failing delivery, payment of £1,000 further damages. In the case the points raised were more of facts than of law. Briefly, as we gather from the Scottish papers, the case was this: Last year Mr. Clement Shorter, the editor of the "Sphere" and the "Tatler," prevailed upon Sir Henry to sit for a portrait of himself for the "Sphere," and they went together to Mr. Crooke's for the purpose. The copyright in this portrait was to be Mr. Shorter's. Then, at Mr. Crooke's solicitation, Sir Henry gave him a sitting for himself, the copyright in this portrait being Mr. Crooke's. Several portraits were taken, and some were rejected by the sitter as not being satisfactory. The question seems to have been whether the picture reproduced by the defendants was the one taken for Mr. Shorter or the one in which the copyright is held by Mr. Crooke. The one side asserted it was, and the other averred it was not. Sir Henry was in the wintess-box for about an hour under examination and cross-examination. Lord Ardwall, in giving judgment for the two defendants in the case, and finding them entitled to expenses, gave his opinion at some length. His Lordship said the principal question which fell to be disposed of in this action was whether the pursuer was the true proprietor of the copyright of the large full-length photograph of which the portraits in the "Sphere," the "Dundee Advertiser," and the "Society Pictorial" were reproductions. It seemed settled that if a person went to a photographer and asked for a sitting he was entitled to the copyright of the photographs then taken, it being presumed that he was liable and intended to pay for them. On the other hand, it seemed that if a photographer invited some celebrated person to give him a sitting, and the person agreed to do so, the copyright to the photographs was the photographer's, even though the sitter should afterwards pay for copies. Further, if a third person

employed a photographer to take the likeness of another person, whether that person were a celebrated person or not, and arranged for a sitting accordingly, the photographs taken at such sitting belonged to the third person, and he was liable to pay for the sitting. His Lordship had come without any difficulty to the conclusion that the truth of the matter was that the sitting at which the photograph in question was taken was a sitting given at the request of Mr. Shorter, as acting for the "Sphere" newspaper, and that he was *prima facie* entitled to the copyright of all the photographs taken at that sitting unless it could be shown that Sir Henry Irving or Mr. Shorter himself agreed to the copyright of any of the photographs becoming the property of the photographer or other person. That, his Lordship thought, had not been shown with regard to the photograph in question. On the contrary, his Lordship held it proved that it was taken for Mr. Shorter, and that he was the person entitled to the copyright thereof. The next question was whether the copyright of the photograph in question, though taken at Mr. Shorter's sitting, had become the pursuer's property by agreement with Mr. Shorter or Sir Henry Irving, and the first inquiry into the facts which now arose was at what stage of the sitting was the photograph in question taken. There was a slight conflict of evidence between Sir Henry Irving and Mr. Crooke on the point, but Mr. Crooke's evidence was not very distinct, and his Lordship attached little importance to it in view of his letters. He should, therefore, in the absence of anything else to the contrary, accept Sir Henry Irving's evidence as correct, that the full-length portrait was first taken. His Lordship therefore attached no weight to the alleged contract by which the pursuer maintained that he secured to himself the copyright of the large photograph in question. On the facts his Lordship held the truth of the matter to be that the whole sitting was given by Sir Henry Irving and accepted by the pursuer as a sitting for Mr. Shorter, and that so far from the pursuer having proved that the photograph in question was in an exceptional position as regarded Mr. Shorter, it had been proved that it was the first taken, and therefore belonged to Mr. Shorter, by whose request and for whose behoof alone Sir Henry Irving gave the sitting.

BAS Relief Photographs.—In the City of London Court on Thursday last, the Taber Bas Relief Photographic Company, of 115, Newgate Street, sued Mr. Beaufoi Moore, barrister, 145, Fleet Street, for £6 11s. for supplying a dozen enlarged photographs in bas relief of his late wife from a photograph. The defendant said that the work was done very badly, and that he and the plaintiffs' artist destroyed all the photos except one, which he kept as a curiosity. Mr. George Cruikshank, the great-nephew of the famous artist of the same name, said that the bas relief photo was a gross libel, and it turned a pretty woman into a guy. The Judge said that the defendant had countermanded the order after seeing the proof, and was thoroughly justified in doing so, as the process had destroyed the likeness. The raising of the nose had entirely changed the appearance of the lady. In the original the nose was straight, and in the plaintiffs' work it became curved. The shape of the chin had been altered, and it ceased to be a faithful reproduction of the picture that the plaintiffs had to copy from. Judgment for the defendant, with costs.

A PHOTOGRAPHIC Transaction.—In reference to the claim of Messrs. Alphonsus John Smith and Co., photographers, of Moot Hall Chambers, Wigan, heard in the Wigan County Court, and reported in our issue last week, the plaintiffs inform us that they only purchased the business in March last, whereas it was urged by the solicitor for the defendant that plaintiff had taken two years to perform the contract.

THE BEGINNINGS OF GELATINE EMULSION.

To the Editors.

Gentlemen,—It gave me great pleasure to see in your historic page a reproduction of the advertisement I sent to your journal thirty-two years ago. That advertisement did wonders! It started a revolution which has now reached the ends of the earth, and produced results no one ever dreamed of then. It brought me letters from the principal cities of Europe and America, and started several Paul Prys on priggish expeditions to Peckham. But that is a sad story better buried.

It was a mistake quite fatal to my interests to issue those bottles of emulsion. The first washed emulsion ever made, be it noted. The weather then was just as it is now—very warm. The gelatine decomposed, and that gave the whole thing away.

Yet I have my consolation—my loss was the world's gain. Several large fortunes have been made out of it by the enterprising traders, and it has put a healthy hobby within easy reach of millions, for it made photography mere child's play compared to what it used to be. So I content myself, and cherish the hope that I shall do better with my next venture, which you will hear of soon. I will be something simple in the colour way.—I am, yours faithfully,

JOHN BURGESS.

71, Stillness Road, Forest Hill, S.E.

July 15, 1905.

COPYRIGHT AND FREE SITTINGS.

To the Editors.

Gentlemen,—I would like to have your opinion as to copyright and permission of reproduction on the following, which happens here in France, and may also in England:—I subscribe to a weekly illustrated paper, price 12s. This includes a coupon allowing a photograph to be taken free of all charges by a well-known photographer. I go there, and two negatives are taken of different positions. One of these two is given free of charge, as agreed, and the other one is left at your option, but charged for 5s. This amount I paid and got one copy of each position. Now what I want to know is: 1. Have I paid now for the two views, and can I reproduce them; one was paid for cash 5s., and the other inclusive in the 12s. of the subscription of the periodical? Or, 2. Can I only reproduce one, and which, the 5s. one or the 12s. one? My personal opinion is that I can reproduce both—but I would like your opinion, as similar things may happen in England.

A. LEVY.

Asnières, July 17, 1905.

[We must confess that we are not well-versed in the copyright laws of France. In England the copyright in the portrait paid for by the sitter belongs to him. The copyright in the one taken on behalf of the newspaper would belong to its proprietors, and not to the sitter.—Eps., B.J.P.]

THE R.P.S. SELECTION COMMITTEE.

To the Editors.

Gentlemen,—Will you kindly make public in an early issue of the *BRITISH JOURNAL OF PHOTOGRAPHY* that the announcement in the Royal Photographic Society's exhibition prospectus, to the effect that additional names would be added to the Selecting and Hanging Committee, is now withdrawn. No alterations in the constitution of that body will be made.—Yours faithfully,

J. MCINTOSH, Secretary.

66, Russell Square London, W.C.,
July 14, 1905.

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

Leak, 60, South Parade, Bradford. Photograph of "Bramley Prize Band." ry Llewellyn Higgins, The King's School, Grantham. Photograph of His Majesty the King Driving from Peel Castle, August 25, 1902.

Allison & Co., Scotch Street, Armagh, Ireland. Photograph of House Part at Castlebellingham, July 4, 1905. Photograph of the Marquis and Marchioness of Bute taken at Castlebellingham, July 6, 1905.

Ham Henry Hudson, 243, Gooch Street, Birmingham. Photograph of Flowers and Leaves comprising "Rose," "Ivy," "Forget-me-Not," "Pansy," "Poppies," and "Wallflowers," in Six Circles with Border round each and Language of the Flower inscribed thereon.

J. McBurney, 405, Stretford Road, Manchester. Photograph of Miss Hickman with Bouquet Presented to the Queen, July 13. Photograph of the Queen Receiving a Bouquet from Miss Hickman. Photograph of the Lord Mayor's Carriage and Occupants taken in the Royal Procession at Manchester. Photograph of Royal Deaf and Dumb School. Stand and Occupants, Erected for Royal Visit. Photograph of the King and Queen immediately after the Presentation of Bouquet to the Queen.

M. Cromack, 30, Newboro', Scarborough. Two Photographs of the Rev. T. E. Lindsay.

CIOS.—We have refused to be the medium for further announcements. As your case stands, we should advise you to ask the police in your town to have the party called upon.

REIGN JOURNALS.—Can the French or Belgian photographic journals be seen in London? An answer in your "Answers to Correspondents" column would greatly oblige.—INTERESTED.

At the Royal Photographic Society, 66, Russell Square, W.C., or the Patent Office Library, Southampton Buildings, Chancery Lane, E. C.

ASHLIGHT AND FERROTYPES.—We want to work dry-plate ferro-types by an artificial light. We have ferrotype plates of the same speed as Imperial ordinary 88 H. and D. Can you inform us if a Todd-Forreth flash lamp, enclosed in a tin case 3 ft. by 2 ft., and having a blue or violet glass front, with a continuous flash of four seconds, and lens at $f/4$, would work?—H. BLACKBURN.

Certainly it would work, provided your lens works at a reasonably large aperture, say $f/8$. There is no necessity to have blue or violet glass in front of the tin case. If it is necessary to keep the smoke in, use ordinary white glass.

WAXING PRINTS.—Will you be kind enough to give us, through your next issue, a reliable formula for waxing plate glass so that the prints will not stick to it? We have tried various formulae, but have failed to get a reliable one, and consequently have had great loss and disappointment through the prints sticking. We are at present using: beeswax, 15 grains; benzine, 3 oz. We tried aluming the prints this week because of the heat, but

they stuck just the same. If you can help us, we shall be greatly obliged.—STICKON.

If the prints, after washing, are treated for ten minutes to a 10 per cent. formaline bath and then squeegeed, we do not think that any trouble of sticking will be met with. Even better than plain beeswax is a mixture of ordinary resin ointment, 1oz., benzole, 2 oz. The resin ointment can be obtained from any chemist: it should be melted and then the benzole added, away from any light, and a little of the mixture poured on the glass, which should be quite clean, and then the glass polished with the mixture. Another simple method is to use ordinary soap liniment, and clean the glass with this. If the glass is absolutely clean, which may be secured with a mixture of ammonia and methylated spirit, there is no need to use any waxing mixture.

COLOURED MINIATURES.—Could you inform me how P.O.P. miniatures are coloured—those advertised largely with gilt rim for about 1s. 6d.? They give the appearance of being washed with dyes. Also are they permanent? Should be glad if you would oblige through your paper.—C. SMITH.

We should say that the cheap results were obtained by the use of aniline dyes: exactly the same effect may be obtained by using aniline dyes mixed with weak albumen solution, but it is far preferable to use some of the stable tinting media such as are advertised every week in our pages.

MANXMAN.—We do not think that there is any doubt that the stains are produced either by imperfect fixation or, more likely, hypo introduced into the toning bath. Absolute cleanliness is a *sine qua non*, and there is not the slightest need for you to have hypo, or a dirty towel, anywhere near the toning bath.

LOST PARCEL.—Last February I sent a negative to the Enlarging Co., Bradford, Yorks, for an enlargement. They advised me they had sent the enlargement and negative on March 9 per Midland Railway Company. I advised them I had not received it. They have written to the railway company, and they, the railway company, reply they are looking into the matter. This was two months ago. Since then I have written to the railway company in Bradford without receiving any reply. Three weeks ago I wrote them again, sending in a claim for cost of enlargement, which I had paid for, and one dozen cabinet photographs which I have lost the sale of through the negative not turning up. The amount of the claim is enlargement 4s., one dozen photographs 15s., carriage 5d., total 19s. 5d. Would you advise me what to do?—J. C. GARNER.

The only thing to be done is to sue the railway company in the County Court for the value of the picture, the negative, and for the damage sustained through its detention. You will have to prove in the court that the parcel was received by the railway company. This the enlarging company can do for you by showing their receipt for it.

COPYRIGHT.—Will you kindly assist me in a question of copyright? I recently photographed an American aerial cyclist and high diver during a public performance in the park. The picture turned out to be one of the most successful ever taken. I had not been asked to take the photograph, but when the performer saw it, he asked me to sell him some copies, which I did. I have since had the photograph registered. Now the questions I should like your opinion on are:—1. Was it necessary for me to have asked the performer for permission to photograph the performance? 2. Did I, by selling the copies, to the performer, lose my right to the copyright? 3. Can I prevent the

performer or committee who engaged him from getting a half-tone block made from the pictures I supplied?—**IAGO.**

1. In the circumstances, as it was a public performance, we should say not. 2. No, you did not. 3. As the copyright is yours, you can restrain anyone from infringing it.

RIGHT TO SELL.—I have taken a snap of a group without their knowing anything about it. Can anyone in the group prevent me, or claim damages, for selling copies to others, without their permission?—**DOUBTFUL.**

This is a moot point. If there is anything in the picture that is offensive to any of the parties, or would hold them up to ridicule, you could certainly be restrained from publishing it. Why not ask the parties in the group if they have an objection to its sale? That would be the best thing to do.

COPYRIGHT QUERY.—I write to ask you if it is possible for me to have the rights reserved of a negative I had given me by the son of a gentleman who took it, but who has been dead for a few years? If you would kindly answer this in your columns I should be pleased. I may mention that it is very valuable, and should like to know what it would cost to have the copyright of same.—**D. McH.**

The copyright is vested in the one who took the picture, but his executors can assign it to you, and you can then register it. The assignment must be in writing, and should bear a six-penny stamp. The fee for registration is 1s., with a penny for the form. If you send us two prints from the negative, and the 1s. 7d. in stamps, we will effect the registration for you.

NATIONAL.—We have written to the firm, and hope that the matter has been put straight by this time. If not, you had better ask the police in your town to make a call on the firm.

A POINT OF ETIQUETTE.—I am a photo-engraver (master), and dabble more or less with a hand camera week-ends and holidays, using the results where possible in my business as a comparatively small side line. Would I be eligible to compete in the usual non-professional classes at photographic exhibitions?—**A. H. E.**

We ourselves would regard photo-engraving as quite distinct from photography, and you would thus be classed as a non-professional. But possibly others might disqualify on the ground that your livelihood was essentially photographic.

A FORMULA QUESTION.—We are at present using here a German P.O.P. The maker's formula for toning bath is as follows:—Sulpho-cyanide of ammonium, 3 parts; chloride of aluminium, 2 parts; sulphite of soda, $\frac{1}{2}$ part; water, 600 parts; chloride of gold (1 : 250), 45 parts. I do not quite understand what relation a part of the solids, as given above, has to the fluids (water). Perhaps you could simplify it for me by putting it in the usual English way—grains and fluid ounces—in your "Answers to Correspondents" next week.—**PRINTER.**

The formula can be written as follows:—Sulpho-cyanide of ammonium, 130 grains; chloride of aluminium, 87 grains; sulphite of soda, 14 grains; water, 60 ounces; gold chloride (1 : 250), $4\frac{1}{2}$ ounces.

RETOUCHING "E. F." AND "B. W."—You have both only mastered the rudiments of retouching, and have a great deal to learn before you can call yourselves really competent retouchers. The modelling is very defective, the touch weak, and "B. W." has placed too much work on the old man's face, and so affected the character and likeness. "E. F." has made a similar mistake with the woman. Be bolder in the touch for faces displaying character, for over-fineness and over-working only produce a mawkish effect. You certainly need finishing lessons. If you are clever receptionists, spotters, and printers,

you might command a guinea a week in a good firm, but you probably only receive half that sum in the majority of houses.

TELEPHOTO QUERY.—Is it possible with the telephoto lenses on the market to take instantaneous photographs of moving objects, etc., or does the increased length of focus make this impossible? Is the exposure very much longer than an ordinary lens or much the same?—**SENILIM.**

It depends on the working aperture of the positive lens, and on the magnification, assuming the former to be that of a good anastigmat, say $f/6$, and the latter to be, say, 5, the actual working aperture of the telephoto becomes $f/30$, and you will understand that the conditions of light, subject, and place must be very favourable to permit of instantaneous work. In usual circumstances, exposures of about one-quarter of a second are about as quick as can be satisfactorily given.

R. A. DAY.—We believe the wholesale vendors of the camera are Messrs. Smith, Clerkenwell Close, E.C.

BITUMEN-BICHROMATE.—Will you kindly furnish me with a good formula for a bitumen-bichromate emulsion for etching purposes? Will you kindly say, also, if turpentine would be the best developer?—**A.**

We know of no such process, and we can see no way in which it could be worked. Are you not under a misapprehension?

J. HARRIS.—The emulsion is not washed at all, but coated as it is after mixing. We should say the card was rather too poor in quality.

PLATINUM TONING.—Has the platinum meta-phenylenediamine bath given on page 544 of to-day's B.J., when used for C.C. matt, to be used after the gold bath or without? What is meta-phenylenediamine, and what is the cost of it?—**OLD CROW.**

The gold bath should not be used. Meta-phenylenediamine hydrochlorate is a definite salt, which costs about 1s. 8d. per oz., according to Merck's list.

NOTICE TO LEAVE.—I should feel much obliged for your advice on the following:—1. A young assistant in my employ was granted a week's holiday although he had only been employed barely six months and was allowed an additional week. On the first day of the holiday he wrote saying that he expected his salary doubled when he returned, and as we replied we could not grant same, he gave a week's notice in return. What redress have we as he has not returned and we paid him for the week of holiday? 2. When should the week's notice take effect in this case?—**HOSBORNE.**

1. We do not well see that you can expect any as you gave the holiday, though it was not nice behaviour on the part of the assistant. 2. From the week it was received.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Printing on Platinum. A correspondent draws our attention to the July issue of a magazine in which is one of those articles for the beginner that we all know so well, the kind of article which scatters "fascinating" and "beautiful" in its preamble, and at the fifth paragraph traces itself up with the exquisite phrase, "Now to our nuttous." Platinotype is our writer's theme, and he is good enough to say "many professionals cannot work platinotype, and consequently they have to get them done, and there are two profits to make instead of only one," which remark our correspondent thinks will have a damaging effect on the profession. Let him not despond. We can assure him that what the Reverend So-and-So says in the — is not going to damage the photographic profession. A writer who wildly generalises: "A platinotype is permanent, a silver print is not," surely does not expect to be received as an authority.

Another Colour Process. The colour process for the week ending to-morrow, July 29, is an electrical one. According to "Electricity," "Certain substances, such as selenium, have an electric resistance varying with the degree of light, and, when such a substance is used as an electrode, and the image projected on it, a galvanic deposit would be formed, with a rapidity varying with the intensity of the illumination. Though the difficulties seem formidable, experiments are stated to be in progress with anodes of different kinds, prepared by exposing to light in a bath containing lead oxide in solution with potash." We look forward with interest to seeing results by this galvanic process, which is actually less novel than our contemporary appears to think.

Photographic Copyright in France.

Another decision in the law of photographic copyright in France is reported in the "Daily Telegraph" by the Paris correspondent of that paper. The issue is similar to, but more definite than is, the case referred to in our issue of June 9. In the present case it appears that a portrait of some musical celebrity had been reproduced in a newspaper from a negative taken by M. Nadar, the well-known Paris photographer, and the editor refused payment. His counsel in court argued, rather disingenuously, that the French copyright law of 1793 protects writers', artists', and composers' works, but not photographers'. The obvious reply was that in 1793 photography had not been heard of. Counsel then drew attention to amendments made to the same law as recently as 1902, in which photography was not mentioned. The inference was that a photograph, not being a work of art, no copyright could be claimed by the author. The Court, however, decided that in the case of a photographer whose name is well known to the public "his celebrity is not merely due to his skill in the manipulation of purely mechanical processes, but to the fact that his works bear the mark of personal talent, and constitute, therefore, works of an artistic character." The editor was accordingly sentenced to pay M. Nadar £2 for his picture. This decision appears to finally settle the question as to whether the photograph or the photographer is the chief consideration when deciding if the production is a work of art.

The Proof Grievance and Cheap Copies.

The difficulty of dealing with the sitter who complains that proofs are not satisfactory and then straightway has them copied or enlarged was recently emphasised in these columns. It was also pointed out that when a number of untuned prints are submitted they are not all returned, and the retained ones are afterwards toned and mounted by some amateur friend, or by a local chemist, who caters for amateurs. If this thing is done it is clear that the order the professional would otherwise receive for duplicates is, to some extent, curtailed. But is this practice followed to the extent that some have alleged? We are inclined to question it, though there are cases, no doubt, where the thing has been done. But cannot the photographer combat the practice in a very simple way? If he imprints with a rubber stamp, on the background near the head, such words as "Proof to be returned" or "Unfixed proof," reproduction would bear the imprint and be useless, and it could give no offence to the customer. This course would be much better than such intimation.

as that all proofs not returned will be charged for, because this rule, as many know, is difficult to enforce without, at times, giving offence to the customer. If some reducing agent, such as a little pyrogallie acid or, say, some hypo were incorporated with the ink, anyone attempting to tone the unfixed prints would quickly find something wrong with his toning bath as well as with these prints. Of course, if finished proofs were branded in the way suggested, a print or two would be wasted at times; but that, after all, is but a trivial matter, for the photographer would have the satisfaction of knowing that unpaid-for proofs were not being utilised in place of duplicates which otherwise would have to be ordered.

New Scheduled Poisons.

The Privy Council have approved the recommendation by the Pharmaceutical Society to place a number of substances on the schedule of bodies to be deemed poisons within the meaning of the Pharmacy Act of 1868. One of them is mercuric iodide, the constituent of the well-known Edwards' single solution intensifier. In this form, and in the newer Lumière intensifier, sold both in the solid and liquid state, mercuric iodide has hitherto been free for sale by anyone; but henceforth only certificated pharmacists may sell it in small quantities. Therefore, photographic dealers should beware lest unknowingly they expose themselves to prosecution for infringement of the Act. Mercuric sulphocyanide is also placed on the schedule, but as its photographic properties are unimportant, it scarcely calls for mention.

Poisons and the Poisons Act.

An inquest was held at St. Pancras one day last week on the body of an unfortunate young woman who had taken some oxalic acid in mistake for Epsom salts. She found out her error almost as soon as she had swallowed the poison, and there is little question that had an antidote been at once administered no great harm would have resulted. It appears from the evidence that the oxalic acid had been used for removing some stains, and had afterwards been wrapped in a paper without a label on it, hence the accident, the acid being very like Epsom salts in appearance. Oxalic acid is one of the scheduled poisons, and can only be sold by pharmaceutical chemists; but, as we have often pointed out before, accidents with poisons usually happen when in use, bottles of the solutions made with them not being labelled, or, as in this case the paper being changed. It is not unusual for chemists to parcel substances in two papers and to put a label on the outer one only, and, as often occurs, this, in opening the packet, is torn and thrown away, and the stuff kept in the unlabelled piece. The Pharmacy Act is framed, ostensibly, to safeguard the public, and it would be well if it enforced that each paper should bear a "poison" label. The Pharmaceutical Society, which takes such an interest in the "safety of the public," might enforce upon chemists the necessity of putting on the labels of the poisons they vend the antidotes for them, and the measures that should be taken in case of their being accidentally swallowed. Had this been so in the case just cited, a life would have been saved, as an antidote, in the shape of some chalk or common whiting mixed with water is quite effective. Common whiting is to be found in every house, and lime water, which is better perhaps, is to be had at the nearest chemist's. Again, with bichloride of mercury, if the whites of eggs be immediately taken, the effect of the poison will be at once counteracted. If such intimations as these were placed upon the poison labels lives might frequently be saved.

A Bichromate Fatality.

In our issue for July 7 (see page 536 ante) is a report of a case of suicide by bichromate of potash. It is the first case of suicide by this salt we have heard of, though there have been one or two cases of death resulting from a solution of it being drunk in mistake for beer. At the inquest on the body of the suicide, the doctor is reported to have said that one-fifth of a grain was enough to have killed her, and she must have taken about 36 or 40 grains. The statement that the fifth of a grain should cause death is certainly astounding. This would make bichromate of potash a more deadly poison than the commercial cyanide of potassium. We should almost have doubted if the full quantity alleged to have been taken would, in the ordinary course of things, have had a really fatal effect. Bichromate of potash, though poisonous, is not a scheduled poison, and had it been of such a deadly nature, there is little question it would have been scheduled. Surely the doctor, in his premises, is entirely mistaken, or has been misreported?

Explosive Flashlight.

The accident at the General Post Office some months ago caused by the transmission of a packet of flashlight cartridges, was alluded to in our columns at the time, but we may refer to the incident again as we now have before us the twenty-ninth annual report of H.M. Inspector of Explosives just issued by Messrs. Wyman and Sons. It will be remembered that a small packet, on being thrown into a basket, exploded and set fire to other parcels. It was found to contain a dangerous form of flashlight powder made up into "sachets" intended to be ignited by pulling a loop. The sender was not aware of their dangerous character, having been assured by the French firm from whom they were obtained that they were safe. H.M. Inspectors state this to be the second instance during a year of such assurance being given in regard to dangerous explosives sent from France. It is suggested that before ordering similar articles traders should communicate with His Majesty's Inspectors, an offer which photographic dealers may be glad to bear in mind.

Certificates by Exam.

From time to time the question of a diploma for photographers has been raised by correspondents in our columns, and the idea is often expressed that something of the sort would not only improve the status of the professional, but what is evidently more to the point with the writers in question, put money in their purses by the elimination from competition of those with no diploma to show. One may well ask, what is the value of a certificate? It must be well within the experience of many that the best doctors from the point of view of ordinary bedside practice are by no means those with the highest examination qualifications. They may be, but they are not necessarily so. The oft quoted instance of the small value of examination certificates or degrees may be cited again: How often do Senior Wranglers make any mark in after life? In fact, how often are they heard of again outside a very limited circle? We should be the last to decry the acquirement of theory in addition to practice, the two together are most helpful to each other, but the mere theorising without any knowledge of practical conditions is of little use. Yet in many instances the theorists are those who would secure the best positions in a mere examination.

Practical Examinations.

It may be urged that examinations for photographers should be practical as well as theoretical. The City and Guilds' examinations

ude a practical test, the value of which was eulogised a contemporary a week or so ago. As a matter of fact practical test applied to candidates in the ordinary is so absurdly simple that any intelligent amateur month's standing could pass it easily. But assuming ally stiff examination, both practical and written, what d the granting of a diploma to successful examinees ve? Nothing more than that a certain amount of tsmanship had been acquired. Success in photophy as a business is not a matter of craftsmanship to great extent. It is far more a matter of ready adaptat- to varying conditions, of aptness to grasp the aliarities of clients and of personality. And who can raise these qualities in an examination? Examinas- and certificates have their value, no doubt, but it is practical man who scores, the man who can "do gs."

* * *

P.P.A. Certificates. The above considerations should confirm the views of those who hold that the Professional Photographers' Association, in granting certificates, is wise to take as a proof of competency the testimony of past and present employers of the assistant. That plan, though put forward by the P.P.A. as a provisional one, to be replaced possibly by a system of examination, has the merit of including the personal element as it applies to the practical side of a photographer's business. Hence the certificate is a guarantee of the examinee's record, based on persistent work, not on one heroic effort to pass the examination. Whatever merit there may be in a written practical examination—and there are duties which such test can usefully fulfil—the testimony of an employer is means of certification which has strong claims to retention, and the Association will be wise never to forget its social value in such a profession as photography.

* * *

Deceptive Light. The bright blue skies we have had of late have proved very deceptive to many experienced outdoor photographers, who have surmised that the light was much better than it actually was, and, as consequence, their negatives have turned out to be considerably under-exposed instead of being, as was expected, the over-exposed side. An amateur recently showed us some negatives—the result of a day's outing—which were considerably under-exposed. On telling our friend of the fault with them, he seemed somewhat dubious, as he held that the plates were those he always used, with the same speed of shutter, and a stop only one size smaller than that he generally employed in a much inferior light. A smaller stop, he told us, was used because of the exceptional brilliancy of the light. With a cloudless blue sky such as we have had of late, the light has been really very deceptive, being very deficient in actinism. The direct sunlight has produced strong cast shadows; there has been no diffused light from clouds to soften them, as a result negatives have been under-exposed in the shadows. Some days last week the light was quite deceptive and was equally as deceptive to novices. In lighting, also, the light in the shade has been very slow at midday, through the cloudless sky. We are, of course, speaking of the light we have had in the London district during the past week or two. In other districts it may have been different. Our object here is to point out to novices that when there is a clear dark-blue sky about light clouds, it may be taken for granted that there is comparatively very little action in the light, and that a fairly long exposure will be necessary to obtain detail in the strong cast shadows.

PRINTING PROCESSES.—IX.

THE FIXING AND WASHING OF PRINTS.

In this series of chapters on the modern printing processes it is scarcely necessary to say anything on fixing and washing prints in special reference to each kind of paper; save for certain minor differences, what applies to one applies to all.

It will be sufficient therefore to deal with these two important operations in the making of a print once and for all at the length they deserve, and leave the reader of the past and future articles to refer to what now follows. At the same time too much stress cannot be laid on proper fixing and washing, for upon them depends the life of the print.

It is immaterial whether the print is on albumenised or P.O.P.; for the same facts must be taken into consideration. Perfect fixation is the complete solution of the silver salts left in the paper, and without entering into the chemical questions of the formation of the various double hyposulphites of silver and soda, it will be sufficient to point out that there should always be a considerable excess of hypo, that the temperature of the bath must not be too low, nor should the bath be used too long. Another point is that a used bath should not be exposed unduly to the air, as is often the case when it is allowed to remain for days in an open dish; under such conditions decomposition sets in and silver sulphide is precipitated and the bath becomes acid.

If the prints are thoroughly washed prior to toning, and an alkaline toning bath be used there is not much chance of their carrying acids into the fixing solution. Yet it is strongly recommended by many authorities to make the fixing bath distinctly alkaline, either by the addition of carbonate of soda or ammonia, the latter being preferable as it certainly exercises a slight solvent action on the silver chloride.

The strength of the fixing bath may vary from 1:10 to 1:6, the former being the strength usually employed for albumen paper and the latter for P.O.P.; beyond this strength it is not advisable to go on account of the danger of blisters.

Exactly how long prints should be immersed in the fixing bath cannot be definitely stated, but fifteen minutes is not too long, and they should be kept on the move the whole time, and also kept well below the surface, for it has been proved that hypo in the presence of oxygen can dissolve metallic silver, and the image in all printed-out papers is in an extremely fine state of division.

There are doubtless many of our readers who can recall the old practice of washing albumen prints, when twelve hours or an all night's soaking or washing in running water was considered to be absolutely essential. With the introduction of gelatine surfaced papers, this was found to be impracticable, for, especially in warm weather the gelatine film was so softened by the prolonged washing that it either dissolved in patches or was so tender as to bear no handling.

At the Photographic Convention in 1894 (*THE BRITISH JOURNAL OF PHOTOGRAPHY*, Vol. XL., p. 511) Messrs. Haddon and Grundy read a paper in which they proved that ten minutes' washing of albumen prints in running water was sufficient to remove the whole of the silver and sulphur salts that can be washed out and that a small quantity of silver still remained in the paper in some form even after nineteen hours' washing in running water, but its amount was no smaller than at the end of ten minutes' washing. The quantity of sulphur left in the

paper at the end of ten minutes, washing was no more than was originally in the paper.

In the following year (*THE BRITISH JOURNAL OF PHOTOGRAPHY*, Vol. XLI., p. 570) the same experimenters proved that with gelatino-chloride paper the whole of the silver was also removed by ten minutes' washing. Further, that no silver remains in the print as in the case of albumen prints, and therefore this paper is not so liable to discolouration as albumen prints. Prolonged washing merely removes some of the alum which is used to harden the film.

It would seem, in the face of the above experiments, somewhat supererogatory to adduce further testimony on the importance of short but efficient washing, but M.M. Lumière and Seyewetz have also attacked this subject (*THE BRITISH JOURNAL OF PHOTOGRAPHY*, May 16, 1902), in another manner, and proved that if a print is washed in successive changes of water, the total consumption being about a pint and a half, it is more efficiently washed than by the use of about 17 gallons of running water. This is an extremely important point where the water supply is limited.

Summarising Lumière and Seyewetz's paper the method

to be adopted is to allow about $1\frac{1}{4}$ ounces of water for every 12 square inches of print (that is, practically a quarter-plate), to soak the print or prints, and if more than this area is washed then the water must be proportionately increased for five minutes; the print should then be lifted and drained well, placed on a hard surface and well squeegeed with a roller squeegee, and the operation repeated eight or ten times. When more than one print is washed at once the prints may be placed in a pile and subjected to the squeegee.

In the face of these facts, the use of hypo-eliminators would seem superfluous. Their action is generally assumed to be the oxidation of the hyposulphite to a higher sulphur compound, but one must not forget that we have not only hyposulphite of soda, but the hyposulphites of silver to take into account, and it may be questionable whether the higher compounds of silver and sulphur are more soluble or more stable than those which exist in the print as it comes from the fixing bath. In particular cases where economy of time is the main point they may be extremely useful, but for everyday work we may surely rely upon plain water, economically but efficiently used as indicated above.

PHOTO-MICROMETRIC METHODS.

In making measurements of minute bodies by means of photography, there is an opportunity of using a method giving very accurate results, and, moreover, capable of being read in a scientific manner. It is a matter for regret that such a method is not more frequently employed in describing the scale of magnification of photo-micrographs. To say that a microscopic object shown in a photograph is magnified sixty diameters is to give a very indefinite idea as to its length, breadth, or distance between parts. Then again, in computing the amount of magnification in diameters, too much is taken for granted if it is assumed that the eyepieces and objectives are accurately named as to their focal lengths.

While the following method is by no means new in principle, there are modifications possible, which, as far as the writer is aware, have not been advocated. This method of recording the size of the object photographed does not interfere with the usual procedure to obtain a photo-micrographic negative, until after the plate has been exposed, and the required negative obtained. Then proceed as follows:—Remove the object from the stage of the microscope, and substitute for it a micrometer ruled in hundredths and thousandths of an inch, or fractions of a millimetre, without disturbing the apparatus, so as to get the same degree of magnification as when the plate was exposed. Take a pair of spring dividers, having sharp points; set these points to the lines now projected on the focussing screen of the camera, preserving the measurement until the photographic negative has been developed, washed, and dried. Then with the dividers the recorded size of the micrometer lines can be marked off along the edges of the plate, and these marks joined by ruling lines parallel, and at right angles to each other, across the film of the negative, with a sharp point. By this means the photograph is divided into squares as shown in Fig. 1, and if required these squares may be again mechanically sub-divided.

Assuming that the negative be quite dry when thus scored, these lines will appear black on all parts of the print, and

possibly may be difficult to distinguish on such areas as are black on the print or dense if the positive be a lantern slide.

If, after the negative is dried, it is placed in a damp atmosphere where the gelatine film can take up a small amount of moisture, and so become very slightly softened, and if, while in this condition, the film is scratched with a point slightly blunt, rounded, and at the same time well polished and smooth, a striking modification is obtained, the advantage of this proceeding being that in no part of the print will the

Fig. 2.

lines be difficult to see, for while the lines print black on the white places and half-tones of the positive, there is a slight ridge of gelatine raised on each side of the lines by the steel point, and this appears on the dark parts of the positive as two fine white lines with the black measurement line between them. A black line running through a black area bordered on each side by a white line, is demonstrated in Fig. 2, which

Fig. 1.—Spiracle of Dytiscus.

Fig. 3.—*Ecidium Berberidis*.

ILLUSTRATIONS TO "PHOTO-MICROMETRIC METHODS," PAGE 584.

is a photo-micrograph under low power of a measurement line, on a lantern slide positive, which has been printed from a negative treated in such a manner.

When two or more plates are being exposed on different objects or magnifications, and many measurements are being taken, the records may be marked on a strip of soft copper, vulcanite, or some such material, on which marks can be made, without injury to the points of the dividers. One leg of the dividers should be put into a common centre, and a small arc scratched with the other leg. These arcs should be numbered, its negative having the same number written on it, so that when all the negatives are ready for scratching its own record can be found on the strip of copper and transferred to the film.

In treating negatives that are to be subsequently enlarged, lines should not be drawn across the whole surface of the film, but only such a distance in from the edges as will be trimmed off the print, or covered by a cut-out mount. It will be manifest that in the enlarging of the photographic image the lines will be correspondingly enlarged, and will become coarse and unsightly. If the print is to be mounted with a cut-out mount and the marks are on the edges of the print, as recommended, fine lines connecting them are drawn by means of a draughtsman's ruling pen charged with Indian ink, after the print is mounted on its cardboard support. The lines of ink will be easily distinguished in any part of the print. But if the enlarged print is to be mounted on a

"stuck on" mount, the micrometer record marks will be trimmed off before the final damping, so before trimming the lines should be ruled by means of a lead pencil, these pencil marks being inked over after the print is mounted and dry. Another method of applying an actual scale to photo-micrographs is to so arrange the photograph as to leave space enough on the longer side of the plate to take a diagonal division scale, constructed from the recorded micrometer lines as in Fig. 3. A coat of a thin opaque varnish, a little wider than the space covered by the scale, makes a good ground to work upon, and may be rendered still more pleasant to draw on if the gelatine is removed from that part of the plate occupied by the scale, and the varnish laid on the bare glass. When constructed in this way, the scale adds to the clean appearance of the finished print.

It should be scarcely necessary to state that the unit of the scale—inch or millimetre—also its numerical value, must always appear on the print. It will be readily understood that in printing measurement lines on a print photographically, that any stretching or shrinking of the paper when wet from chemical treatment, or when mounting, that the scale or lines move with the paper.

Of course, though considerable accuracy may be claimed by these methods, the fact remains that there is no perfectly accurate method of measuring the edges of a microscopic object.

THOS. C. HUGHES.

THE WEEK IN HISTORY.

The Photographic Franchise.

ONE of the possessions of the Royal Photographic Society is a document of great historic interest in connection with the early days of photography. Fox Talbot, as I have mentioned before in these notes, patented all his discoveries, and while these patents were in force it was felt that the progress of photography was severely handicapped. It was therefore suggested by some one—I do not know whom—that possibly Fox Talbot would relinquish his rights were he offered a baronetcy. A preamble relating to the matter was drawn up and separate sheets circulated for signatures. It is one of these sheets which the R.P.S. possesses, the gift to it from Mr. John Leighton, who himself obtained the signatures which it bears. Mr. Leighton tried to obtain Faraday's signature, but without success, for Faraday, as is well known, set his face against any sort of patenting of scientific discoveries, and would have nothing to do with it. However, Talbot was approached by Lord Rosse, the President of the Royal Society, and did publicly resign his rights in his process, except in its application to portrait taking. It is exactly fifty-three years since this took place, but Talbot afterwards brought an action against those who were working the wet-collodion process, which he held to be an infringement of his calotype method. This action, however, he lost, and from that time forth the photographic field was free to all.

Photography Without a Dark Room.

Many estimable people there have been since the invention of photography who have proposed to introduce certain methods or apparatus to photographers for the convenience of the latter, and incidentally to the profit of the estimable parties. Usually these introductions are obviously the productions of persons entirely ignorant of practical photography and destitute of any intention to employ in their own practice the appliances for which they have frequently obtained Royal Letters Patent. One of the earliest of such "inventions" was that of T. E. Merritt, a drawing-master of Maidstone, whose patent for "ap-

paratus for taking photographic pictures in the open air" was applied for almost exactly fifty-one years ago—on August 1, 1854. That was in the first year or two of the wet-collodion process, and Mr. Merritt's idea was to dispense with the yellow tent by building a magazine for collodionised glasses at the back of the camera, and below it an elaborate system of trays and baths for developing and fixing the exposed plate. I cannot recollect that anything ever came of this early patent for "daylight photography," and when I look at the drawings in the patent specification (No. 1,696) I am not surprised that it shared the fate of similar unpractical suggestions, made before and since.

Talbot's Photography of 1835.

Perhaps it is not generally known that the first authenticated piece of photography which Fox Talbot did is still in a very fair state of preservation. It was made in August, 1835, and therefore is at least seventy years old at the present time. Mr. C. H. Talbot has the original in his possession. It is the image of a latticed window in Lacock Abbey, and is mounted on a piece of paper on which Talbot had written:

Latticed Window.
(With the camera obscura.)
August, 1835.

When first made the squares of glass
about 200 in number could be counted,
with the aid of a lens.

Mr. C. H. Talbot has stated that they can still be so counted, so that the negative—which is what the relic is—is not very much different from what it was when Talbot made it. The window can be identified in Lacock Abbey, and the claims of Talbot in his first paper viz., that he was bringing forward the results of work done several years previously—can thus be substantiated.

HISTORICS.

THE ACCURATE PRODUCTION OF SELECTIVE COLOUR-FILTERS.

(A Communication to the Paris Academy of Sciences.)

the facility with which, at the present day, photographic materials of almost any description of colour-sensitiveness can be obtained is rendered of much greater importance the use of coloured light-filters for the transmission of certain portions only of the spectrum. Our interest in this question has led us to design screens by a scientific method, according to which any given description of colour can be reproduced identically, and is therefore capable of exactly imitating the work of the original. The principle of the method is simple. A given weight of dye is diluted in a given volume of aqueous gelatine solution. Distributing the same volume of this solution over the same surface, the same weight of dye will occur per unit area, and the two colours will be identical. In practice the coloured mixture is spread on the surface of an optically-worked glass, and, after drying, the film of gelatine is covered by glass, also optically worked, and the two united by Canada balsam. If plane-parallelism of the filter is necessary, the two outside surfaces are then optically worked.

In the case of preparing a filter to possess certain properties previously decided on—i.e., absorption of certain particular parts of the spectrum—it is necessary to adjust, with the greatest possible precision, the weight of the dye or dyes before distributing these latter over the film. To avoid the disturbing action of the gelatine, Canada balsam, etc.—factors which are far from negligible—but also to avoid errors, which arise from differences in the absorptions of the dyes, according as the film is wet or dry, the following method has been devised:—Taking first the case of a single dye, the coloured gelatine mixture, prepared as above described, is applied to two glasses, one placed horizontally and the other inclined so as to form an incline of 2 in 100. The volume of solution applied to the first glass having been determined with care, the weight, p , of colouring matter per unit surface is known. After drying, the gelatine film has a thickness, e .

The gelatine having been flowed over the inclined plate and dried, the latter is divided into two parts along its length, and to one of these strips a white glass is cemented with Canada balsam. A screen is thus obtained, constructed in the same way as the one required, but with the weights $p_1, p_2, p_3 \dots$ of dye per unit area varying in the same proportion as the thicknesses $e_1, e_2, e_3 \dots$ of the gelatine film. This screen is then placed in an apparatus, by which the various parts can be gradually moved before

the slit of the spectroscope. The latter is illuminated by a narrow beam of light, projected perpendicularly on to the screen by means of a cylindrical lens, which forms the image of a slit, the latter being brightly illuminated by the condenser of the projection lantern.

By means of the eye-piece of the spectroscope, the portion of the spectrum corresponding to that, for which the screen should show the maximum of absorption, is observed, and the screen is then slowly displaced until this result is obtained. The portion corresponding to the coloured region, which was illuminated at this moment, is then noted. On the other piece of glass, the thickness e_1 of the gelatine film is measured. The weights of dye being proportional to the thicknesses of the films, it is easy to calculate the weight per unit surface required for the depth of colour corresponding to that we require:—

$$\frac{e}{e_1} = \frac{p}{p_1} \quad \text{or} \quad p = \frac{e_1 p_1}{e}$$

When the colouration of the screen comes from two dyes, from each are prepared (as described above) a plain and a graduated screen. These latter are placed in juxtaposition by cementing the films with Canada balsam, so that the deepest part of the first comes next to the lightest part of the second. We thus obtain a screen in which the weights p_1, p_2 , of each dye are inversely proportional. Passing this screen over the slit of the spectroscope, after we have located the region corresponding to the colour required, it is not difficult by measuring the thickness of the gelatine on each plate

to find the ratio $\frac{p_1}{p_2}$.

By this method we have succeeded in preparing a number of colour-filters, among which may be named a green screen, with maximum luminosity, corresponding to $\lambda 530$, a filter which with the Jougla "orthoscopic" plate permits of exactly the maximum colour-sensitiveness of this emulsion for the special radiation.

Another screen was an orange-yellow, prepared for the maximum colour-sensitiveness of this plate at $\lambda 588$. Another was a yellow filter absorbing up to $\lambda 500$, and another red filter absorbing the whole of the more refrangible part of the spectrum up to $\lambda 630$.

These first results given by the above method convince us of the possibility of preparing light-filters in a thoroughly scientific manner.

M. F. MONFILLARD.

FOREIGN NOTES AND NEWS.

Opaque Collodion and Celluloid Films.

GERMAN patent of the Aktiengesellschaft für Anilinfabrikation 51,213, (of December 5), has just been published, in which it is pointed out that a mixture of:—

Celluloid	20 gms.
Acetic ether	100 gms.
Methyl alcohol	120 gms.

After evaporation, an enamelled white film, but that if the quantity of methyl alcohol be increased to 250 gms. an extremely fine enamelled white film is obtained. Matt films are also obtained by diluting the alcohol-ether collodion with acetone, or acetic ether collodion with alcohol, or alcohol collodion with methyl alcohol. The films thus obtained are strong and may be coloured as desired, and may be used for the so-called baryta films for emulsion paper and for coating glass, wood, or leather.

For Three-Colour Workers.

Hans Schmidt gives, in the "Central Zeitung für Optik und Mechanik," some useful hints on building a camera for three-colour work. In the first place, he points out that it is better to obtain the filters from the firm whose process is to be worked. If the filter is to be placed near the lens, the glass of which they are prepared should be optically worked, but if they are used close in front of the plate this is immaterial. If, however, the distance between filter and plate is more than 2 cm., they must be flat, and flexible filters cannot then be used. It is practically immaterial whether the filter is placed in front of, or behind the lens, but in the latter place it will lengthen the focus slightly. The worst position is between the combinations of the lens. The disadvantage of having filters close to the plate is the necessarily large size of the fittings to change them, and therefore, the author suggests the use of two plate-glass reflectors at a

right angle to each other, the front one being at 45 deg. to the axis of the lens, an idea which has been repeatedly used. The red sensitive plate is placed opposite the lens, as there it receives about 64 per cent. of the light transmitted by the lens, the green sensitive plate is placed opposite the first reflector and receives 20 per cent. of the light, and the blue sensitive plate opposite the second reflector, where it receives about 6 per cent. of light. The accurate ratio of the exposures must be obtained by adjusting the filters. If the reflectors give double outlines the backs must be coated with coloured varnishes.

The Home Preparation of Coloured Screens.

Hans Schmidt, in the "Photographisches Wochenblatt," warns photographers against assuming that accurate filters can be obtained, although one may use specific formulæ with given quantities of dyes, gelatine, etc., and even when the dyes are obtained "chemically pure" from a given maker. The reason for this is stated to be that the manufacture of these dyes is so complicated that the colouring power cannot be guaranteed twice alike.

Silver Phosphate Collodion Emulsion.

Professor Valenta, in the current number of the "Photographische Korrespondenz," gives the following method of preparing the above, which is not only suitable for printing out, but also for development with an acid developer:—

Raw collodion 3-3½ per cent.	1,500 ccs.
Phosphoric acid 20 per cent.	20 ccs.

Mix and add—

Citric acid	60 gms.
Alcohol	100 ccs.

To this collodion the following ammoniacal silver solution should be added:—

Silver nitrate (powdered)	60-80 gms.
Liquid ammonia .880	q.s.

Enough ammonia should be used to give a perfectly clear solution, this should be warmed and

Absolute alcohol	250 ccs.
------------------------	----------

added, and, this added to the acid collodion in small quantities at a time with thorough shaking. Then should be added:—

Ether	250 ccs.
Glycerine alcohol 1 : 1	20 ccs.

Coated on matt baryta paper, this emulsion gives a matt surface paper, which keeps a long time. If printed till the outlines of the image are just seen, full intensity can be obtained by developing with:—

Metol	1 gm.
Glacial acetic acid	25 ccs.
Water	25 ccs.

forty drops of this being diluted with 100 ccs. of water. If the prints thus obtained are treated to the phosphoric acid and chloroplatinite bath they will give beautiful brown to black tones.

Boric Acid as a Restrainer.

Professor Namias has recently strongly recommended the use of boric, or, as it is commonly called, boracic acid, as a restrainer, and states that over-exposure of from 40 to 100 times may be compensated by its use. He suggests that enough of the acid should be added to a 10 per cent. solution of potassium bromide to form a saturated solution, and that 10 ccs. should be added to every 100 ccs. of developer, for which he specially recommends the following formula:—

Sodium sulphite	50 gms.
Hydroquinone	7 gms.
Metol	1 gm.
Sodium carbonate (anhydrous)	30 gms.
Water	1,000 ccs.

As the solubility of boric acid is only 3.5 gms. in 100 ccs. of cold water, one may be permitted to question the value of the addition of less

than two grains to every ounce of the developer, as it could only neutralise a small amount of soda.

Soap in the Pyro Developer.

Franz Hofbauer recommends the addition of a little solution of medicinal soap, the soda and olive oil soap, to the pyro-ammonia pyro-soda developer to prevent the formation of black spots on the plates, which he calls granular fog, and ascribes to the combination of oxidised pyro with the silver bromide grains, which are set free from the gelatine through the large proportion of ammonia or soda. The particular action of the soap is said to be to hold this compound in suspension, or to destroy the stickiness of the gelatine. A 2 per cent. solution of the soap is made in water and filtered, and 2 or 3 per cent. added to the developer.

Violet-Tones on Prints.

Herr Kochler suggests the following method of obtaining a rich violet tone on P.O.P. prints:—The print should be very deeply printed and then toned in a combined toning and fixing bath till it assumes a blueish-grey colour, then washed for an hour, and whilst still wet immersed in a 2 per cent. solution of mercuric chloride. It is stated that the prints at once assume a deep velvety, violet tone, and only require washing for half-an-hour. It is possibly permitted one to doubt the permanency of such prints, as we may assume that the chemical reactions that would occur are analogous to those when a negative is bleached in mercuric chloride, namely, the formation of silver and mercurous chlorides.

Pseudo Photography.

Treating of the Russell effects of metals, etc., on dry plates Merckens of Mülhausen, in the current number of the "Photographische Korrespondenz," points out that many have assumed the action to be due to rays of some kind, and that Aubel has found that resin, copal, and alcoholic solution of phenol exerted the same action. He, therefore, considers that it must be ascribed to some chemical action which agrees with Russell's assumption of its being due to hydrogen peroxide. Blaas and Czernack have called those substances which thus act on plates "photochic," and explained the action as due to the occlusion of ozone, but Merckens states that in very few cases could he detect ozone, and in nearly all hydrogen peroxide. With minute traces of peroxide he detected the first action next the glass, with a celluloid film there was no action, but if the film was laid down on a sheet of glass there was immediate action. Glass, mica, and all metals are absolutely opaque to the action, but appear to retain peroxide most tenaciously on their surfaces. Very small quantities of peroxide will pass through a film without action, but if an opaque substance be placed behind the film, from which one can assume and prove reflection, there will be action, as simple reflection cannot produce alteration in the peroxide or its rays, the only explanation is a collection or concentration of the peroxide vapour on the surface of the plate. The author states that the peroxide vapour is dissolved by the emulsion, which always contains some water and that the alkali present in the emulsion converts the peroxide into water and nascent oxygen and this is the active agent. (Except for minute traces of alkaline and earth salts from the washing water, most emulsions contain no alkali.—Eds. B. J.) As a proof, however, of his contention, Merckens states that peroxide has no action on an acid emulsion, or one absolutely free from water, nor on acid collodion emulsion, or on a wet collodion plate. If, however, these films were made, alkaline action took place at once. If a dry plate is exposed to peroxide vapour and then bathed in peroxide, the preliminary action is destroyed. A film saturated with peroxide vapour and immersed in potash lye behaves quite differently to one immersed in a mixture of potash and peroxide, for the latter develops to a vigorous image, whilst the former only shows a slight trace. Plates dried at 120-130 deg. C till their weight was constant showed not the slightest trace of an action with peroxide.

The author concludes that the action of peroxide and "photechie" is a chemical one and should be ascribed to the nascent oxygen. An interesting experiment of the author's, is the production of duplicate negatives. A negative is dried at 120 deg. (unnecessary, the negative is kept in the dark for a long time), and is then printed on fresh celloidine paper, either by the arc or sunlight, about as usual for toning. The print is then pressed in contact with a dry plate, in the dark for twenty-four hours and then developed and a duplicate negative is obtained which, however, shows the paper grain.

The action of various metals on dry plates is in the following order:—Magnesium, aluminium, zinc, cadmium, nickel, cobalt, and lead, then tin, but the action of the last is so faint that there is practically no effect on the plate. The author here remarks that Krone has proved that dry plates can be kept perfect for twelve years if packed in tin-foil. This series corresponds with the electric resistance of the metals, so that the capacity to form peroxide agrees with the electro-positive character of the metals. Kahlbaum's "actinography" would appear to be rather due to electrical phenomena than radiation, and the phenomena would appear to be connected with earth currents.

SAVING BROKEN NEGATIVES.

R. O. H. BOYE, writing on this subject in the June issue of the *Monthly Review* of the P. A. of California, says:—

In the professional studios, where a great number of negatives are handled daily, it frequently occurs that valuable plates, which cannot be replaced, are either cracked during the process of printing or are badly broken by having been dropped accidentally. In the latter event, if the negative be broken into several sections, probably the best way to get satisfactory results is by the method of production, viz., mounting the pieces upon a clear glass, fitting them together accurately, and then exposing for a positive. Careful etching and retouching on this plate will eliminate a greater part of the cracks showing, after which a negative can be made and the etching done thereon.

Stripping Processes.

Where a negative is divided into but two or three pieces, stripping the film from the broken parts and floating on to another glass is the method that should preferably be adopted. Many formulae for this process have appeared in print, and work with various degrees of success. Hydrofluoric acid, a solvent of glass, while it does the work satisfactorily, is a messy solution at best and requires very careful treatment, or the film is easily torn. The formaline method is to be preferred as the safest process, allowing, as it does, a greater latitude in the handling. The formula recommended is thoroughly reliable, and also has the merit of being simple work. Some objection has been made to formaline on account of the danger in its use—said to injuriously affect the eyes and the hands—but as the solution diluted for use is very weak no greater caution need be taken than that used with a number of other photographic chemicals.

The Formula.

A stock solution of 10 per cent. of caustic soda should be made. The formaline recommended is the 40 per cent. solution supplied the trade:—

Solution A.

Caustic soda, 10 per cent. solution	½ oz.
Formaline solution	1 oz.
Water	5 oz.

Solution B.

Hydrochloric acid C. P.	1 dr.
Water	8 oz.

The negative to be treated should first be thoroughly cleaned from all traces of varnish or retouching medium by rubbing it with alcohol or turpentine, as the case may be, and left to soak in warm water until the film is softened. Before doing so, however, use a blunt knife and a straight-edge and scratch a line through the film to the glass around the four sides of the negative close the edges. This will give a clean edge for the solutions to act upon, and also facilitate matters considerably in stripping. The pieces of the negative to be stripped can be supported upon a sheet

of plain glass and attached thereto with rubber cement, shoemaker's wax, or any medium of a similar nature that will not dissolve in the solutions. This is for convenience in handling, and not absolutely necessary, as each piece can be stripped separately, if preferred. After soaking in the water for about a half-hour immerse the plate in Solution A for five minutes, rinse slightly, and then transfer to Solution B for a similar period. Rinse well after this bath and place on the table, face up, ready for stripping. Dampen a clean sheet of writing paper large enough to lap over the plate all round. Lay this on the film and cover with a blotter. Squeeze the paper into contact with the film by rubbing with your hand on the back of blotter. Take some blunt-pointed instrument or a knife and start a corner of the film by gently lifting it up with the paper. It will come away readily enough, but watch carefully for places that are inclined to stick; touching them lightly with the blunt point will assist in making them yield.

How to Transfer the Film.

A gelatine-coated plate previously prepared should be in readiness. The formula for this substratum is the same used for the carbon process, and consists of gelatine, 1 oz., soaked in water, 16 oz., till softened, then dissolved by gradually raising the temperature of the water over the stove nearly to the boiling point; then add chrome alum (20 gr.) which has been dissolved in warm water (1 oz.) gradually to the gelatine solution drop by drop, stirring constantly to prevent precipitation. A clean glass plate immersed in this solution while still warm and left to drain and dry is what is required. Rinse the surface of this plate well with water and lay flat on table. The film can now be lowered into position on its new support and rubbed into contact under a blotter. Remove the paper, and should any bubbles remain between film and glass they can be worked out by dabbing them lightly with the finger towards the edge of the plate. The remaining pieces can now be transferred in the same manner, but in adjusting the pieces together it is important that an overlap of about one-sixteenth of an inch be allowed for shrinkage in drying. While drying these places where the film overlaps it should be occasionally dabbed or pressed into contact in order that it adheres tightly to the glass at these points. After drying, should the overlap be too great, scraping off the surplus film with the etching tool will result in securing a perfect match.

Negatives that are simply cracked and not broken through the film are quickly transferred by this method. This process is also used for the reversing of negatives for the carbon process where a single transfer print is desired. Where an enlargement of a negative is wanted, say of a cabinet to a 10×8, the stripping process is the quickest solution of the problem. The hardening bath is omitted and plates are simply treated by immersing in the hydrochloric acid alone. The film expands considerably after leaving

its support, more than doubling its former size. Should this expansion prove too great, immersing it in alcohol will cause it to contract to the point wanted, or almost back to its original size.

Negatives enlarged in this manner, however, become considerably thinner in density by the expansion of the film, and, unless the negative was originally very dense, strengthening with mercury must be resorted to after negative is dry, when there will be no risk of the film leaving its support.

THE ROTARY PHOTOGRAPHIC COMPANY'S ANNUAL OUTING.

WEXMOUTH was the chosen locality this year for the sixth annual outing of the employees of the Rotary Photographic Company, Limited, and on Saturday, July 15, upwards of 300 journeyed per Great Western Railway special corridor train from Paddington and West Drayton to this charming seaside resort. On previous occasions a day in the country has been the rule, so this year's departure was thoroughly appreciated, especially in view of the fine weather that prevailed. Dinner was served at the Hotel Burdon (facing the sea) at 12 noon.

The committee who made the arrangements consisted of Messrs. Ley, Judge, Kral, Shrimpton, Hay, Lowry, A. W. Rushbrook, Armour, Wicks, Balch, Putman, Newbury, J. H. Tarr, Erskine, and King (representing the London office), with Mr. H. D. Hill as hon. secretary. There were 50 members from the London office present. A beautifully got-up souvenir card was presented to each employee, and is an excellent example of the fine photographic work of the firm.

At the dinner Mr. J. H. Balfour presided, and was supported by Mrs. Balfour, Mr. and Mrs. Haenel, Mr. Hall (from the London office), etc.

Mr. Haenel who was loudly applauded, said it was an agreeable task for him to bid them welcome once more, on behalf of the directors, on their sixth annual outing, and, looking at them, he wondered at the number. He remembered the time, five years ago, when they started for their first beanfeast in a brake or two, or it might have been a pony and trap. There were only about a dozen then, he thought, and now they were nearly 300, and that was a very good sign, for it meant good business relationship, and he hoped the increasing enjoyment of the outing. He wished them all a pleasant afternoon and another pleasant outing next year, and then he hoped there would be still increased numbers.

Mr. Hall, of the publishing department; Mr. Ley, on behalf of the employees; and other speakers voiced sentiments suitable to the occasion, and the party eventually reached West Drayton at 11 p.m., after a most enjoyable day.

THE SECOND AMERICAN PHOTOGRAPHIC SALON.

THE preliminary prospectus of the second American photographic Salon is to hand, and the particulars indicate that the enterprise is in a flourishing condition. Local juries have been appointed in all the great centres of the United States, and the work selected by these juries will be sent for the consideration of a "national preliminary jury," drawn from the best-known pictorial workers in the country. This jury will select about one thousand frames, to be further acted upon by a "final jury" of painters.

As a recognition of the intrinsic value and artistic merit of photographic pictures, the following purchase funds have been established—selections to be made by the final jury of painters:—The American Federation of Photographic Societies offers \$100 for the best picture exhibited, without restriction as to subject. "The Country

Calendar" (13, Astor Place, New York), the new magazine of outdoor interests, has established a purchase fund of \$50 for the best study of a rural outdoor subject accepted by the jury. "Landmark" (Editorial Office, Hartford, Conn.), a new illustrated publication now in course of preparation, has placed in the hands of the American Federation of Photographic Societies \$50 for the purchase at the second American salon of the best landscape embodying some particular scenic landmark in any State or territory of the United States.

Foreign entries are to be sent, mounted or unmounted, but not framed. All entries from Great Britain should be sent to arrive by September 20 to H. Snowden Ward, 6, Farringdon Avenue, London, E.C., marked "For Second American Photographic Salon."

All entries must be delivered at the rooms of the Metropolitan Camera Club of New York, 100-102, West 101st Street, New York City, U.S.A., on or before November 1, 1905.

Full particulars can be obtained from H. Snowden Ward as above or from the secretary, Wm. T. Knox, 279, Washington Street, New York City, U.S.A.

THE FREE PORTRAIT TRICK.

AMONG the firms carrying on the "free-portrait trick" in this country at the present time, special reference has been made in "Truth" to the Crown Art Co., of 115, Seven Sisters Road, N. Possibly in consequence of the criticism they have incurred, this firm now makes it fairly clear in the original contract that the "free portrait" will only be delivered on paying the price of the frame; and they appear to make it a practice to show a "rough sketch" of the promised portrait when the frame is ordered. But they have evidently borrowed from Mr. Tanqueray, of Paris, the little dodge of squeezing customers by refusing to return the photograph entrusted to them for enlargement, as will be seen from the following letter:—

"Dear Sir,—Our collector informs us you decline to pay instalments due on our picture until it is finished. We therefore inform you that we do not finish pictures until half is paid, the balance to be paid on delivery. Trusting you will let us know if this will suit you, we remain, yours truly,

"THE CROWN ART COMPANY.

E. H.

"P.S.—Should we not hear from you within three days we shall destroy enlargement with original."

The customer to whom this was written had refused to order a frame, or pay anything on account, because he was dissatisfied with the portrait. The threat, therefore, to destroy the "original," i.e. the photograph entrusted to the firm for enlargement, speaks for itself. "Truth" further remarks: "It often happens that the photographs parted with in this way are the only copies in the possession of the owners, and they are naturally valued, or the owners would not desire to have them enlarged in crayon. Sometimes, of course, they are photographs of deceased relatives. All the free portrait dodgers know well enough, and they trade in this way on the value attached to the photograph. It may be as well to point out to any one who receives a threat like the above that the company have no right whatever to destroy the photograph, and could be sued for damages if they failed to return it in good condition. It may be added that in the above case the customer states that some of his friends who had fallen into the hands of the Crown Art Co. had paid their money, and had obtained the "free portrait" framed, but when it was delivered, they could see no difference between the finished article and the "rough sketch" previously submitted to them in order to secure the order for the frame."

Photo-Mechanical Notes.

A Modified Woodbury Process.

HERR A. KOLBE has recently patented (D.R.P.K. 27552) in Germany a modification of the Woodbury process. Instead of using a pigment print to obtain the matrix, he employs a swollen bichromated gelatine relief, which is obtained in the usual way by exposure of bichromated gelatine. From this relief a cast is taken in marble cement, which sets in a few days extremely hard, and is then coated with tin foil and then forms the matrix. A warm gelatinous ink is poured on to a smooth or matt sheet of metal, celluloid, or glass, and the matrix pressed on to it so as to form an image, and then a sheet of paper is squeezed down on to the image, and the whole set on one side to dry, and the paper bearing the print is then stripped from the metal or celluloid. According to the "Zeitschrift für Reproduktionstechnik," from which this note is extracted, the results are extremely good, and can hardly be told from a photogravure; but the process is considerably cheaper, as a cheap press can be used which will give one print a minute. After the pressure of the matrix on the gelatine ink, it only takes thirty seconds for this to set. The new process is also suitable for trichromatic work. From the three negatives, obtained through the screens in the ordinary way, three positives are made on one plate, and from these swollen reliefs obtained as described above, and then the matrices cut up and filed to register. The first impression is made in blue, then, on top of this, the red, and finally the yellow. Though this is the reverse order to that usually followed, it is obvious that, as the paper is squeezed to the yellow and the print stripped in the finished print, the order of the colours becomes as usual. The colours used were prepared by Gleitsmann, of Dresden, and they are stated to be quite transparent and permanent to light. Absolute uniformity of results is said to be obtainable by this process; and the extreme transparency of the pigments used gives a brilliancy of colouring hitherto unattainable in three-colour prints.

Photo-Lithography.

A photo-lithographic process for preparing a design on a zinc or similar lithographic printing or transfer plate, and dispensing with paper transfers, is patented by Mr. T. McLaren. According to an account in the "British and Colonial Printer," the plate is sensitised with bichromated albumen, gelatine, or the like, and is exposed under a negative. The surface is then smeared with a greasy substance permeable to water, but insoluble in turpentine or other ink solvents, and is developed in water to wash away the unaltered parts. The greasy substance consists essentially of a gum resin soluble in chloroform, as, for example, of bitumen, dragon's blood, gum mastic, chloroform, and benzol; oil of lavender may be added, and an aniline dye may be used as an indicator. In the case of bichromated albumen, alcohol is added to make it flow or dry evenly, the ingredients being water, white of egg, ammonium bichromate, ammonia, and alcohol.

In "Newspaper Illustrations," an eight-page sheet printed on ordinary "half-tone" news paper as supplied to a London illustrated daily, Messrs. Carl-Hentschel, Ltd., make a profound impression of their ability to produce half-tone cuts for all classes of publications, running into immense editions. "Newspaper Illustrations" makes a convincing show of what can be done, predicts great things from the general introduction of half-tones, and has some interesting things to say on the effect of the half-tone movement in newspapers on other sections of the press.

PHOTO-MECHANICAL PATENTS.

Application for Patent.

The following patent was applied for on July 12:—

ROLLER PRINTING SURFACES.—No. 14,047. Improvements in and means for the production of engraved printing surfaces on rollers and plates. Richard Bertie Fishenden, 17, St. Annes Square, Manchester.

New Books.

"Photography for the Press." By the editors of "The Photogram." Published by Dawbarn and Ward, Farringdon Avenue, London, E.C. Second Edition, price 1s.

"This is the golden rule in press photography:—Study your editor: through his journal." Its importance would almost warrant its being printed at the head of every page of this little book.

This is the theme to which the authors have attuned their lay in the second edition of "Photography for the Press," and no doubt their practical experience in the disposal of "photograms" of topical interest to the editors of the current illustrated papers has fully demonstrated its truth. There can be no contradiction to the statement that photography now plays a very important part in the illustrated journalism of the world, and that, in a great measure, the editorial department of most of the illustrated papers is dependent on the contributions of outside workers for representations of local events. With this fact in mind, therefore, it will be seen that the publication under consideration, dealing, as it does, with the practical side of the work of the photographic journalist, is likely to be of widespread usefulness. The utility of the previous edition is evidenced by the fact that it is the subject of a paragraph in the current annual report of the Photographic Copyright Union, recommending it to their members.

For the second edition the matter has been almost entirely rewritten; while sections on picture postcard work are entirely new. Apart from the advice and instruction given for the benefit of the aspiring photographic journalist, the advantages of the work as a profitable side-line open to professional photographers are not lost sight of.

"Das Radium und die radioactiven Stoffe." By Karl Frhr. v. Papius. Berlin: Gust. Schmidt. 1905. M. 2.

It is, of course, quite natural that a discovery of such far-reaching importance of so marvellous a nature as that of the radio-active elements should have given rise to a flood of literature, both from the pen of capable investigators and in the lay Press. The effusions of the latter were more or less prompted by the facility of creating sensational "copy," and the publication of an unpretentious, popular, but sober, account in book form of the various phenomena of radio-activity may therefore be hailed with satisfaction. "Das Radium," whilst devoid of all mathematics, covers the whole ground which has been so fruitfully explored by physicists like Rutherford, Soddy, Ramsay, J. J. Thomson, Curie, and Giesel. It is clearly written, it confines itself to the subject of radio-activity, and it avoids the temptation and error, usual in a work of this scope, to touch upon other correlated subjects in an attempt to introduce the reader to the phenomena. The illustrations materially aid the understanding of the experimental arrangements whereby, step by step, the properties of those minute quantities of radio-active bodies have been elucidated. Great prominence is given to the important aid which photographic methods have rendered in these investigations, and a special feature is made of pointing out—as far as possible—the practical possibilities of the various characteristics. A pity the volume is not in English.

"Stand-Entwicklung," by E. Blech. Published by Gustav Schmidt, Berlin. Price 1.80m.

Stand development has apparently not found such favour in England as in Germany, if one may judge from the fact that this is the second edition of a work devoted entirely to practical details of the process, whilst here we have no work and but little literature on the subject. This work is written in simple language, and numerous working formulæ for suitable developers are given.

The "Agfa" Handbook.

A new edition of this little guide to the use of the "Agfa" developers and photographic specialties is to hand, and it well bears out the good impression created by its predecessors. It is comprehensive and informative, and the photographer who possesses a copy need never go wrong in exposure and development if he follows the instructions given in its pages. Each of the preparations produced under the aegis of the Actien-Gesellschaft für Anilin-Fabrikation is dealt with in turn, and the various formulæ that have been advocated from time to time in which they are employed are given with full instructions.

"Agfa" developers in cartridge form, and also in solution ready for use, are the subject of a separate section, and the good qualities of Rodinal here comes in for prominent attention. The other specialties include "Agfa" intensifier and reducer, acid fixing salt, varnishes and toning and fixing salts, "Agfa" flashlight, and the Isolator non-halation plates.

A copy of this useful little booklet should be in every photographer's hands, and a copy will be sent by Messrs. Charles Zimmermann and Co., 9 and 10, St. Mary-at-Hill, London, E.C., on application.

"Hauff on Modern Developers" is the title of a compendious booklet issued from the chemical works of J. Hauff and Co., Feuerbach, Wurtemberg.

The Hauff products are almost too well known to English photographers to need comment or further commendation, and this little handbook will be found to deal very concisely, yet exhaustively, with the patent developers, etc., that figure so prominently in most modern formulæ for dry plates and development papers.

The scope of the book has been increased, and the present edition can be regarded as a short guide for photographers, containing valuable hints which will help to overcome many difficulties. For instance, the purpose and properties of the dry plate are discussed, and "exposure" is very fully dealt with both from the theoretical and practical side. Useful exposure tables are given, and the subject of development comes in for a large share of attention. Each well-known developer is treated of separately, and every photographer of an experimental turn will find the pages devoted to "Combined Developers" specially attractive. Intensification and reduction are also expounded, and sundry other photographic processes that come within the application of the products of the firm are considered. It is a most useful little production, and a copy will be sent by the English agents, Messrs. Fuerst Brothers, 17, Philpot Lane, London, E.C., upon receipt of 1d. stamp to cover cost of postage.

"FALLOWFIELD'S COURIER," No. 16.—This little trade journal deals this month with the seasonable piece of apparatus—a dark-room ventilating fan. Other dark-room novelties are also illustrated, including waterproof aprons and sleeves, and new lamps fitted with gelatoid screens, ruled cutting shapes, plate-washer, and new developing dishes, to say nothing of the Taquta automatic camera, are likewise mentioned.

New Materials.

The "Ryston" Electric Dark Room Lamp, made by Reynolds and Branson, 14, Commercial Street, Leeds.

Some time ago we reviewed an early pattern of this lamp and have, for over a year, continuously employed it for dark-room work, and bromide printing, etc. The new 1905 lamp, illustrated below, is very similar in design to the previous pattern, but has several small additional advantages and improvements, that tend to make it invaluable in every dark-room fitted with electric light. The lamp is substantially and reliably constructed, and is handsomely finished in olive green enamel, with nickel-plated fittings and reflector. Two electric bulbs are fitted, one on top with reflector for white light, and the other inside for ruby light. The insulated switch handle on top is safe, and in the new pattern is well adapted for turning on the current to either ruby or white light, or instantly exchanging the one for the other by a small sliding movement. The

ruby glass provided is of special spectroscopically tested description, and it gives a pleasantly soft but brilliant illumination, while its semi-circular shape secures the lighting of the whole developing table. The lamp can be either placed on the table or suspended against a wall, and is an ornament to any dark-room, while its utility cannot be questioned. Gelatoid mediums to fit the lamp can be supplied if necessary, and electric lamps for any voltage are included. The lamp complete with all fittings measures, from base to top of outside light, about 14 inches. The working area of the ruby light is about 8½ in. x 4 in., and the price is 18s. 6d., including flexible cord and connections for existing electric fittings.

Griffin's Special P.O.P. and Tonix, made by J. J. Griffin and Sons, Limited, 20-26, Sardinia Street, Lincoln's Inn Fields, London, W.C.

This new P.O.P. is up to the usual high standard that we expect from Messrs. Griffin, and as it is introduced as being specially suitable for a combined toning and fixing bath, it may claim to be probably the first of its kind. A new combined bath called Tonix is also being issued simultaneously with the paper, and if they are used together, perfectly satisfactory results are obtained, which are claimed to be reliable as to permanency. We can speak as to the satisfactory results from personal trials with the paper and toner, and no doubt will be able to report in a future volume of the B.J. as to the permanency. The toning and fixing bath is supplied

in powder form in boxes of six packets at 1s. 6d., or in tins at 1s. each. Each little packet contains sufficient to make four ounces of Tonix solution, which will tone 12 to 14 $\frac{1}{4}$ -plate prints, or 7 to 8 5×4 to 7 cabinet, or 5 to 6 $\frac{1}{2}$ -plates. This cannot be called expensive, and it is certainly an extremely convenient and simple method of preparing a tone-fixing bath at short notice. The makers claim for the bath that its effect is to take up the excess of silver in the prints, before it can be converted into the harmful sulphide of silver, and if this is so one of the chief drawbacks to the combined bath is removed by the use of Tonix. In practice the P.O.P. is printed out in the usual manner—a little darker than is desired when finished, and good plucky prints are best obtained by printing in the shade. The prints are plunged, without washing, face downwards into the Tonix solution, and are kept moving for ten minutes. They are then washed and dried as usual. The resulting tone is a rich chocolate purple. For colder tones the prints are left in the bath for a longer period, say, twenty minutes; for warmer ones the prints are removed at an earlier stage, and complete fixation is ensured by immersion in a 10 per cent. plain hypo solution for the remaining period up to ten minutes. The P.O.P. can, of course, be toned and fixed in separate baths in the usual manner. It is not recommended to use the Tonix bath a second time, or just as much solution as the prints require and no more should be employed, and after use thrown away. The price of Griffin's special P.O.P. is the same as that now in force for all other P.O.P.'s.

An improved Dark-Room Pin, sold by Houghton's, Limited, 88 and 89, High Holborn, London, W.C.

Messrs. Houghton have sent us samples of the Moore Push Pin, which is exactly similar in appearance to other glass-headed pins of the same type already on the market; but by way of improvement it is claimed that the glass is now made much

tougher, and the points cannot come off. Also, there is no danger of the glass breaking across the bottom, as frequently happened with the older patterns. As the uses to which these little accessories can be put are so numerous, the qualities mentioned will be appreciated by every photographer. They are sold at 6d. a dozen, neatly boxed, and are obtainable through all dealers.

Particulars of the "Elias Patent Fountain Bulb" have been sent us. The apparatus is a neat attachment for emptying bottles or other vessels by air compression. The device consists mainly of an elastic bulb connected with a tight-fitting central tube forming a cap or stopper. The lower part of the bulb fitted to the neck of the bottle is provided with air channels or perforations communicating with the interior of the vessel, so as to exert pressure on the liquid therein when the bulb is squeezed by the hand. The liquid does not come into contact with the india rubber, but is forced by air-pressure through the glass tube, which can be easily detached for cleaning. It forms a most effective wash-bottle, or syringe, and enables a jet of liquid to be maintained for a considerable time. By the use of a pinch-cock, and the detachable non-return valve, sufficient pressure may be introduced into the vessel to ensure a continuous flow of liquid when required without further compressing the bulb, thus permitting the operator the free use of his hands. The syphon attachment will be found useful in photography, providing an even flow of the developing solution over the plate without the necessity of rocking the bath. By tilting the bottle a little on one side the fluid will flow back through the glass tube by gravitation, thus obviating the necessity of decanting

the solution in the usual way. To reverse the action of the syphon so that the solution may return into the bottle, the free end of the tube is dipped into the liquid contained in the developing dish before releasing the pressure from the bulb, and the fingers are released so as to create suction. The price of bulb attachment and valve is 2s. 2d., and it may be obtained from V. Aubrey Elias, 123, Waller Road, New Cross, S.E.

Samples of the Sandhurst Sépia Toner have been sent us by Messrs. Sanders and Crowhurst, successors to Williamson and Co., of Hove, Brighton. This toner is in two solutions and is of the now familiar sulphide type with its equally familiar odour. The tones obtained with it on bromide papers are of a rich sepia, and the ease with which they are produced should make the toner popular. It is very economical. The bleaching solution (No. 1) can be used over and over again, while one dram of No. 2 makes five ounces. The set makes in all 172 ounces, and the price is 1s.

No. 3 of the Kodak Handbook Series deals with "Bromide Papers," and is a comprehensive little guide to the use and manipulation of Kodak bromide and gaslight papers. Full particulars of each brand are given, and the booklet is embellished with half a dozen full-page prints on the different grades of paper made by the firm. Platino-matte, Permanent Rough, White Royal, Nikko, and Dekko are the papers used, and concise directions for sepia toning are included with an illustrative example. The photographs themselves figured prominently in the recent Kodak £1,000 competition, and are excellent examples of pictorial work. The book is published at one penny, and will be supplied on application to Kodak, Limited, 57-59-61, Clerkenwell Road, London, E.C.

A full list of the specialties made and marketed by the Tress Company, of 205, Oxford Street, London, W., has reached us. In it will be found particulars of the Tress Portrait Lamp for use with incandescent gas, also repeating cameras, rapid printers, copiers, vignettors, flash lamps, and many other useful novelties that are likely to appeal to the professional and amateur photographer. This firm has recently moved to larger and more commodious premises at above address, where all their latest novelties are on view.

A superb catalogue of Photographic Objectives and Cameras has been issued by Carl Zeiss, from 29, Margaret Street, Regent Street, London. The specialties of the famous Jena firm are set forth on art paper, and the accompanying illustrations are fine examples of the block maker's skill. A four-colour engraving executed by the engraving department of J. C. Schelter and Giesecke, of Leipzig, is a notable full-page reproduction of a vigorous painting, the reproduction being made with the Zeiss-Apochromat-Tessar lens, Series VIII. The various types of Zeiss lens—the Planar, the Unar, the Tessar, and the Protars are fully described and illustrated; and the telephotographic-objectives, Palnos and Manos cameras, the Verant, prisms, and light filters, etc., that have been described at various times in these pages, are catalogued and their performances demonstrated. As a proof of the high estimation in which the Zeiss productions are held, the statement in the preface of the catalogue that in ten years the combined supply by the Jena firm and their license-holders of anastigmatic objectives has reached a total of 100,000, should carry conviction, if any were needed, regarding the quality of the goods.

An abridged summer catalogue of photographic specialties is to hand from Messrs. Reynolds and Branson, of 14, Commercial Street, Leeds. Rystos cameras and camera sets, lens, enlargers, dark-room lamps, apparatus for ceramic photography, and other accessories for the photographer are listed, and a copy of this or catalogues of the firm's numerous departments for scientific apparatus, etc., will be sent post free on application.

New Apparatus, &c.

The "Argus" Reflex Focal Plane Camera. Made by W. Watson and Sons, 313, High Holborn, London, W.C.

A new pattern of this instrument has been submitted to us, and it only tends to strengthen the good opinion that we formed of its predecessor. The camera, although containing many new features, is not intended to take the place of the original "Argus," which we reviewed last year, but has been put on the market to supply the wants of those workers who require a reflex camera of the usual high standard of Messrs. Watson's productions, but with a square reversing back, which last year's pattern did not possess. Needless to say, the workmanship of the camera is of the best, and although very simple to use it has been specially constructed for precise work, and to fully meet the requirements of photographers who desire to see exactly what they are getting on their plate at the moment of exposure.

Further than this, by an ingenious arrangement of levers the full-sized finder, which is of course the great charm of the reflex camera, is obscured for an extremely brief period only, during the actual exposure

of the plate. The image can therefore be focussed right to the instant of exposure, and can be observed on the ground glass of the protected finder, not only immediately before the exposure, but immediately after. This is a great improvement over the type of reflex camera that totally obscures the finder at the time of exposure and keeps it obscured, as it is then impossible to further inspect the image on the ground glass until the shutter is set again. For press photographers the "Argus" camera will be particularly acceptable, and it is difficult to conceive any type of photography, technical, topographical, or pictorial, wherein it would not be of service. The body of the camera, which is of mahogany, is covered in black morocco leather; all uncovered parts are ebonised, and the metal fittings are finished black, rendering it as unobtrusive as possible. In the quarter-plate size the dimensions of the new square reversing back model are $5\frac{3}{4}$ by $6\frac{1}{4}$ by $7\frac{1}{4}$, which is extremely small for a camera with the qualifications this one possesses. It weighs but $2\frac{1}{2}$ lb., and has a bellows extension of 11 in. It is supplied with the Holostigmat lens, and the extension is sufficiently long to take the single combination. The focal-plane shutter, which forms an integral part of the camera, is highly practical. It gives "time" exposures of any duration, and instantaneous exposures from 1-15th to 1-1200th of a second. The alteration of the slit is made from outside, and the speeds can be ascertained at a glance. The camera (square form), complete with Holostigmat lens and three dark slides, sells at £18 for the quarter-plate size, £20 11s. for 5 by 4, and £24 for half-plate.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes.

The following applications for patents were made between July and July 15:—

ROLL FILM.—No. 14,166. Improved method of using rolled film in cameras. William Augustus Casson, 1, Essex Court, Temple, London, E.C.

STUDIO CAMERA.—No. 14,373. A reflex studio camera. Scotts Studios, Limited, and Frank Piper, 37, King Street, Covent Garden, London.

METAL PICTURES.—No. 14,410. A new or improved process for the ornamentation of metal articles, particularly of oxidised steel, with photographic metal pictures. Emil Jabulowsky and Armand Bourquin, 31, Bedford Street, Strand, London.

ORTHO PROCESS.—No. 14,449. Improvements in the production of coloured effects upon photographic emulsions on any surface, from the action of fluorescent or phosphorescent states of matter. Archibald Campbell Ponton and William Cullen Horne, Rylestone, Bromley Road, Catford, Kent.

TRIPLEX PHOTOGRAPHY.—No. 14,623. Improvements in cameras adapted for use in triplex photography. William de Wiveleslie Abney, Clun House, Surrey Street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

EXPOSURE METER.—No. 16,468, 1904. According to this invention, the proper exposure to give a sensitised plate at the time a test is made is determined by the apparent recognised standard of brilliance or clearness of the object to be photographed when focussed upon a screen. This state of the image is dependent upon the quantity of light admitted to the screen, and this can be regulated at will by means of an orifice of variable size and the variations indicated by a scale and pointer. In the improved exposure meter there is a chamber provided with a lens which has an adjustable shutter arranged so as to admit as much light as

is required at the time by means of a suitable regulator. Opposite to the lens is an orifice which is preferably provided with a lens also. Between the latter and the first-named lens is arranged the screen. The regulating means of the shutter is provided with a pointer, and a scale representing preferably seconds of time and fractions thereof, is marked within the range of the pointer. An auxiliary scale is also preferably provided for compensation for the discrepancy which would occur in the reading if "stops" were used in the lens of the camera. In using the apparatus, the lens 3 is placed to the eye, and the object to be photographed is viewed upon the screen 4. The milled cap 9

is now turned until the image shows a recognised standard of brilliance. The value of the "stop" to be used with the camera is now noted, and the "speed number" value is brought opposite thereto. The number which the pointer 26 indicates upon the scale 23 then represents the proper length of time for the exposure of the plate. William Augustus Brooks and George Andrew Watson, 81, Tower Buildings, Liverpool.

BACKGROUND STANDS.—No. 18,102, 1904. Protection is claimed for a special construction of background stand, for which it is claimed that it permits the use of any desired sequence of backgrounds without requiring the shifting about of any parts, and also avoids the disadvantages incidental to the use of pawls and powerful springs to wind up the background, and to having to hang up a separate background when a variation is desired. Further, the contrivance can be readily taken apart for transport and can be readily set up without the use of tools, and confusion of operating cords is not liable to occur. George Rutter, 181, Wardour Street, London, W.

FOCUSSEING DEVICE FOR CAMERA.—No. 18,455, 1904. The patent specifies the mechanism by which the adjustable part of the camera can be instantly moved into the required position to focus objects at various distances. The full text and figures are necessary to explain the claims. Kodak, Limited, 57, 59, 61, Clerkenwell Road, London, E.C.

FLASHLIGHT.—No. 628, 1905. The patent relates to the electrical ignition of flash powder, and claims the covering of the igniting wire with some material more inflammable than the flash powder. Frederick Fitz Payne, 27, Chancery Lane, London, E.C.

ALTERING FOCAL LENGTH.—No. 1,594, 1905. The invention provides means for changing the focal distance of a lens system by moving one of the components during exposure. A suitable space is provided between the two casings for receiving an elastic or resilient means, such as a coiled spring 4, Fig. 1, which when operating causes a change of the distance between the lenses or lens sets forming the system, and, therefore, a change in the focal distance. The resilient means may be adapted to operate by expansion as well as by contraction. The coiled spring 4, for instance, may first be compressed and then act on the lens-carrying

casings by expansion, thereby increasing the distance between the lenses, and consequently changing the focal distance of the system. If the same spring is fastened to the lens casings and first expanded it will act by contraction, and thereby decrease the distance between the lenses. These elastic or resilient means may be located between the lenses, as shown in the drawing, or they may be outside of one or the other lens. In using the device the release 6 is set into such a tooth 7 as to cause, when released, the desired change of the distance between the lenses and the corres-

ponding change of the equivalent focal distance. Taking, for instance, the device illustrated in Fig. 1, the front lens is pulled out a short distance and the coiled spring thereby expanded. The release 6 is set, for instance, in the first tooth. The object to be photographed is then focussed in the ordinary way, and the shutter, which may be operated by the same bulb as the release 6, is opened, and during the time or duration of the photographic exposure one lens moves gradually, without jerking, towards or from the other lens, whereby the distance between the lenses is varied, causing a corresponding change of the focal distance or equivalent focal distance of the lens or lens system, and producing a photographic negative of even sharpness and without distortion, and giving a true record of the colour value of the original object. U. Nehring, 24, East 21st Street, Manhattan, New York.

In a further patent (No. 1,505, 1905) the same inventor makes similar alterations in focal length during exposure by application of a second lens. The auxiliary lens 4 is set so as to be held by the release 7 under the tension of the spring 8 and outside of the optical axis of the lens system. The object to be photographed is then focussed in the ordinary way, and when the exposure is being made the release 7 is operated and the lens 4 is caused to pass over the lens system and through its optical axis, and

thereby changes the focal distance or the equivalent focal distance of the same during the time of exposure. The auxiliary lens may be made of white optical glass or of tinted or coloured glass, so as to act like a ray-screen or colour-screen for producing orthochromatic or isochromatic effects on the sensitive surface. Means may also be provided for regulating the speed of the movement of the auxiliary lens, and an arrangement of the shutter release and the lens release may be made for operating the same simultaneously. The auxiliary lens may comprise a single lens or a lens system.

A PRINTING MACHINE.—No. 4,150, 1905. A lengthy specification (with drawings) of apparatus for printing a number of photographs from a negative. The claim is for a photographic printing apparatus, with a case having a source of light therein and provided with means for holding a negative and a sensitised surface, a platen, a platen frame movable with the platen, a hand lever, jointed connections between the hand lever and the platen frame for operating the platen, a vertically movable drum having projections of different length upon its periphery, means beneath the drum for retarding the descent thereof, a contact lever arranged within the path of the projections on the drum and connected with a switch to make and break an electric circuit to emit light to the negative, means operated by the platen frame for elevating the drum, a dog for holding the drum elevated, means carried by the platen frame to trip the dog to release the drum, means for adjusting the drum to bring one of the pro-

jections thereon into the path of the switch lever, and means co-operating with the last-named means for predetermining the period of contact between the switch lever and the projections on the drum. Hervey Heman McIntire, South Bend, St. Joseph, Indiana, U.S.A.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—
PIGMENT PRINTING PROCESS.—No. 12,867, 1905. Bühler.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
28.....	Hall Photographic Society	Outing to Selby.
28.....	Cricklewood Photo. Soc.	Outing to Chorley Wood.
28.....	Wallasey Amat. Photo. Soc.	Field Day.
29.....	Birmingham Photo. Society	Half-day Excursion to the Leasowes.
29.....	Manchester Amat. Photo. Soc.	Trip to Delamere.
29.....	Rowes Park and Dis. Ph. Soc.	Outing to Lei h-on-Sea.
29.....	Glasgow Southern Ph. Assn.	Trip to Garthland Estate.
29.....	Woolwich Photographic Soc.	Outing to Waltham.
29.....	Southampton Camera Club	{ "Architectural" Photography. Mr. T. M. Weaver.
August.		
1.....	Rotherham Photo. Society	{ "Natural History Photography."
2.....	North Middlesex Photo. Soc.	{ R. P. S. Lecture.
2.....	Cricklewood Photo. Society	{ Lantern Slide and Print Competitions.
3.....	Hull Photographic Society	{ "Defects and Faults in Negatives, and their Remedies." General Discussion. General Meeting at Society's Rooms

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At a meeting held on July 20 Mr. Freshwater said he had tried stripping the film of a broken negative with hydrofluoric acid, as recommended at the last meeting, but it now showed a line all along the break as of frilling. The film had been in the water twenty-four hours, and had not dried since development. Messrs. Henderson and Teape were of opinion that had the negative been dried before stripping the mark would not have shown. Mr. Rapsom had tried to stop stretching of a stripped film by immersing it in spirit, the result being that the film finished smaller than originally. Mr. Henderson said that a solution of bichloride of mercury and alum would shrink a film to one-quarter of its original diameter.

PLYMOUTH PHOTOGRAPHIC SOCIETY'S third summer outing was at Burrator, some of the party also visiting Sheepstor and Meavy. The next outing is fixed for Saturday next, when Berry Pomeroy Castle will be visited, and members and friends entertained at tea by the vice-presidents, Messrs. F. Blanchard and H. S. Hill.

COMBINED Outing of the East London and South Essex Societies.—Sufficient promises of support having been received in response to the South Essex Camera Club circular re combined outing, the following arrangements have been made:—Meet at Grange Hill Station (for Hainault Retreat) at 3.10 p.m. on Saturday, September 16. A photographic group will be taken at 6.15 p.m. Tea at 6.30 p.m., followed by a social and musical evening. A silver medal is offered by the South Essex Camera Club for the best picture taken on this outing. The members of each society are requested to wear pieces of ribbon, of the colour allotted to them, as a buttonhole. Societies in the East London and South Essex district wishing to join should communicate with the secretary, T. Michell, 180, Browning Road, Manor Park, E., when full particulars will be sent them.

R. BANKS, photographer, of 126, Market Street, Manchester, has been favoured with a command from the King to supply his Majesty with an album of photographs of the recent Royal visit to Manchester.

Commercial & Legal Intelligence

At Hawick, on Wednesday of last week, A. H. Leach and Co. photographers, Brighouse, Yorkshire, applied for cessio against John Allan, of the firm of J. G. Tunny and Co., photographers, Hawick.—Mr. Allan stated that he had no capital when he started business; but he had borrowed money to the extent of £125.—Cessio was granted. The assets were over £8, and the liabilities over £200.

NOTTINGHAM Shopkeepers Defrauded.—The weakness of the majority of people for having their photographs taken has often been turned into capital by the unscrupulous, and a case at the Nottingham Guild-hall last week offered yet another proof of the susceptibilities of the public. Proceeding on well-tried lines, John Henry Newitt, described as a canvasser, of Carlton, induced a number of tradespeople to believe that he was a representative of the "Brunswick Art Company," who were making a "special offer to shopkeepers, giving away £25 in pictures in one week." For 1s. on account he would give them a ticket entitling them to one framed enlargement and six cabinets, and they could pay the balance of 1s. 6d. in weekly instalments, "when they got the pictures." Three tradespeople gave evidence as to purchasing tickets—nothing more or less than advertising business cards—on dates between July 4th and 7th. It was stated that prisoner had no connection whatever with the Brunswick Art Company.—Newitt, who has served in the army, said the cards and the photograph were given to him by a man in St. Peter's Square. He did not know that he was doing anything wrong.—He was sent to prison for seven days on each of the three charges.

DOUGLAS and Walls, Limited.—Registered July 1st, by W. E. Owens, 1, Newton Street, Liverpool. Capital, £2,000, in £1 shares. Objects: To adopt an agreement with W. B. Douglas and T. R. Walls; to acquire the business carried on at 19, Old Hall Street, and Irwell Chambers, Fazakerley Street, Liverpool, as Douglas and Walls; and to carry on the business of draughtsmen, engraving and architectural photographers, printers, drawing office material and general stationers, bookbinders, etc. Registered office, 19, Old Hall Street, Liverpool.

UNSTAMPED Weights.—J. G. Bagshaw, photographic dealer, St. Sepulchregate, Doncaster, was ordered to pay 16s. costs for having unstamped and unjust weights in his possession.

RE William Henry Hayward, late photographer, Streatham, S.W.—The first meeting of the creditors interested under this failure was held at the London Bankruptcy Court on July 18th. According to the debtor's statement he began business 19 years ago. In 1900 he entered into partnership with another person for the purpose of carrying on business as photographers at Streatham. He provided £2,000 capital for the business, while his partner brought into it a stock of negatives. The trading, however, never paid the expenses, and he was compelled to finance the business from time to time. He thought that in addition to the £2,000, which he found at the outset, he had put an additional £700 into the business. The business was a failure chiefly on account of another firm publishing a series of pictures at a rate cheaper than he and his partner could afford to publish them at. In June last year it was arranged that the partnership should be dissolved, but disputes subsequently arose as to the terms of the deed of dissolution, and eventually an action in Chancery was begun by his partner, who claimed £700. The debtor added that he did not consider himself insolvent. No statement of affairs was filed, but it appeared that the liabilities secured, and unsecured, amounted to £9,993 10s., and that the assets were valued at a sum sufficient to yield a surplus of £819 15s. 7d. The public examination was fixed for August 3.

FORGERY Charge Withdrawn.—Frederick Ahrlé, 46, a German subject, described as a photographer, of Cavendish Road, Harringay,

was charged before Mr. Fordham at the North London Police-court, last week, with forging and uttering a bill of acceptance, value £100. The evidence showed that the prisoner was the inventor and licensee of a metatype paper, and was managing director of a company formed to sell the article. His brother, Hermann Ahrlé, was also a director; and another gentleman who held a large number of shares and had advanced considerable sums for the business was Mr. Hugh Henry Francis Hyndman, of Seven Sisters' Road. The latter, who was prosecutor in the case, had advanced the prisoner several sums of money; and when he let him have the £15, he asked for security to cover the £95 he had advanced. The prisoner produced a bill for £100, purporting to be signed by Hermann Ahrlé, but this was alleged to be a forgery, and the present charge was made. After hearing the evidence the judge said, "The signature on the alleged forged bill is entirely dissimilar to the original signature of Hermann Ahrlé. So far as we have to go at present I certainly should not commit the prisoner for trial. In my opinion these proceedings are merely taken to squeeze money, and it is altogether a case that should never have been brought into court." Mr. Fordham marked the charge "Withdrawn" and returned the documents which had been put in.

Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

We do not undertake responsibility for the opinions expressed by our correspondents.

THE CONVENTION ADDRESS—A CORRECTION.

To the Editors.

Gentlemen,—I notice in the text of my address that the name of Professor Wood is erroneously given as Professor Woods.

The mistake originated in the typing of my manuscript, and unfortunately escaped me when subsequently correcting the same.—Yours faithfully,
J. JOLY.

Chorlton, Temple Road, Dublin.

ORTHOCHROMATIC RATIOS OF PLATES.

To the Editors.

Gentlemen,—In your issues of July 14 and 21, under "New Materials," the "Marion Iso Plate" and the "Barnet Roll Film" were reviewed, and figures given for the ratio

blue sensitiveness
yellow sensitiveness

determined by Mr. C. E. K. Mees.

and I think I am right, this ratio has been obtained by determining the speeds behind liquid filters composed of a 1 cm. thickness of 1 per cent. copper ammonium sulphate solution for the blue, and 1 cm. thickness of a 4 per cent. solution of potassium chromate for the yellow (Eder's method), using a "screened acetylene light," would not be as well to state at once that this is not anything like the value of their relative sensitiveness to blue and yellow light as ascertained by these screens.

To obtain an approximately correct figure would be no great difficulty. If the relative brilliancy (regardless of colour) of the light transmitted by these two liquid filters were determined a factor could be obtained, and when the results obtained as before were multiplied by this factor we should then have a figure indicating something like the real "chromatic value" of the plate, and not its relative sensitiveness to two spectrum bands of arbitrarily accepted brilliancy.

And, of course, the lights transmitted by the two colour filters could be brought to equal brilliancy by some means or other, and then, of

course, the ratio of the plates' speeds behind the two filters would be the ratio required; but I think this would present more difficulties than the determination of a multiplying factor for the result.—Yours faithfully,

R. S. POTTER.

97, Belgrave Road, Ilford, E.

July 21, 1905.

[Our correspondent's objection, though not stated so fully as we could wish, is one which we must decline to admit. The question is one which deserves more lengthy treatment than we can give it in a footnote, and we will refer to it next week.—Eds., B.J.P.]

OUR PROGRESSIVE ALLIES.

To the Editors.

Gentlemen,—Recently, while the foremen of our departments were chatting together after the day's work, we thought it an opportune moment to apprise them of the fact that we had seriously thought of reducing their wages, and the wages of everybody else in the establishment, because of some very formidable circumstances which we found to be affecting our business. You should have seen their faces! Their relieved grin was almost as funny when we told them that an important customer in China had been obliged to place his orders for a large contract for postcards from half-tone blocks to a Japanese firm, who eagerly undertook it at the rate of 7s. per 1,000, including blocks.

On hearing of this from our would-be customer, we answered that our raw material would cost almost as much as that, and that we were sure it would interest Englishmen to know how the Japs did it. His reply is that while he is unable to discover any reliable facts about working hours of the Japanese photo-engraving or printing firms, yet he has been informed that photo-engravers and line workers (native Chinese) working about 16 hours a day get paid an equivalent of 4d.

On such a scale of wages as this or anything like it, our Japanese friends will certainly be able to pile up more profit—and a good deal more—on postcards at 7s. per 1,000 inclusive, than we could at twice that price.

We thought it would interest you to know of this little instance.

HOOD AND Co., Limited.

St. Bride Works, Middlesbrough,

July 18, 1905.

THE current monthly catalogue issued by the Tella Camera Co., of 110, Shaftesbury Avenue, London, W., contains as usual, some special bargains in second-hand and shop-soiled photographic goods. Photographers, both amateur and professional, will always find something they want in the Tella lists; and they should arrange to have copies sent them every month. They will be sent post free on application. This firm also makes a specialty of exchanging cameras, lenses, and apparatus generally for either new or second-hand apparatus; and an important feature of their business is supplying every description of photographic goods on weekly or monthly payments.

AN interesting exhibition, consisting of a selection from the photographs contributed towards the photographic survey of Sussex, was opened in the museum of the Technical Institute, Eastbourne, on Wednesday last. The exhibition remains open for three weeks, and no charge is made for admission.

ROTHERHAM Photographic Society.—The forthcoming exhibition of this society is announced to take place on October 18. This is the sixteenth annual exhibition of the society, and although there are open classes, the executive continue to adhere to the rule of "no entrance fees" (lantern slides excepted). Full particulars will be sent on application to the Hon. Secretary, H. C. Hemmingway, Tooker Road, Rotherham.

News and Notes.

MONOCHROMATIC Photographs of the Orion Nebula.—On obtaining a series of spectrograms of the Orion nebula with a small objective-prism quartz spectrograph, Professor Hartmann, writing in "Nature," states that he found that different parts of the nebula emit light of very different composition, whilst large areas, of characteristic forms, shine solely by the ultra-violet radiation at λ 3727. This variety of the light emitted by the several areas of the nebula led Professor Hartmann to employ colour screens in obtaining direct photographs with a Steinheil-reflector of 24 cm. aperture and 90 cm. focal length. Three screens were used; the first completely absorbed all wave-lengths shorter than λ 4800, but allowed $H\beta$ and the two chief nebular lines, N_1 and N_2 , to pass through almost without any diminution of intensity. The second screen freely transmitted all radiations between λ 3880 and λ 3740, but absorbed all others, whilst with the third the absorption commenced at λ 5050, increased rapidly to totality at $H\beta$, extended to λ 4000, and then quickly decreased; until at λ 3727 the transparency was very nearly complete. In this screen the two chief nebular lines were faintly transmitted, but it was an easy matter to eliminate their action by employing a plate of suitable sensitiveness. Combined, the first and third screens cut out $H\beta$ leaving only N_1 and N_2 effective. Marked differences of the intensities of several areas, as shown on the various photographs obtained with different screens, are plainly seen on the reproductions accompanying Professor Hartmann's paper. Evidently the radiation λ 3727 is extraordinarily intense in all parts of the nebula, whilst in some parts it is almost the sole radiation, producing strong photographic images where the eye sees nothing. The nebula G.C. 1180 surrounding the star ϵ Orionis is scarcely visible on the N_1 and N_2 photograph, but it is a prominent feature on that obtained with the ultra-violet light, and is fairly bright on the $H\beta$ plate. This differential action suggests to Professor Hartmann the presence of at least three gases in the Orion nebula, one of which emits the chief nebular radiations, the second hydrogen, and a third, which emits the radiation at λ 3727.

TAKING Moving Pictures Underground.—A series of interesting moving pictures were taken a short time ago by the American Mutoscope and Biograph Company in a section of the subway of the Interborough Rapid Transit Railroad of New York. A number of scenes were included of the stations when the passengers were leaving or boarding local trains, and the results were in every way successful. The light by which these photographs were taken was provided by a number of the Cooper-Hewitt lamps fixed on two flat cars in nine banks of eight lamps each. The lamp known as the "K" type, which is 45. in. long, was used, and the total candle-power of light amounted to 52,500 c.p. The banks of lamps were mounted diagonally across the foremost car, so that the light was thrown immediately in front of the camera, which was mounted on the next car. Each lamp was backed by a polished metal reflector, and the kicking coils by means of which the lamps are started are arranged underneath the frame. The manner of generating the current is worthy of note. A Westinghouse 40 horse-power 600-volt motor taking its current direct from the third rail was mounted on a truck and connected by belt to a 224-kw. Westinghouse 110-volt generator. The various auxiliary apparatus, such as volt-meters, rheostats, switches, etc., were conveniently mounted between the two machines. The work was entirely successful, and during the entire trip only one lamp went out. Some interesting photographs of the cameras and light installation are given in the current number of "The Electrical Engineer."

TRIED by the Camera.—Arthur Duffey, the American sprinter, when touring Australia and New Zealand in company with Shrubbs, was often suspected of "beating the pistol." This was because he was so quick off the mark. So in order (writes a Sydney correspondent of the "Dundee Advertiser") to satisfy disappointed competitors, the officials of the New South Wales Amateur Athletic Association made arrangements, quite unknown to Duffey, for a snapshot to be taken of the start of the 100 yards sprint. The result was convincing. The developed photograph shows the smoke of the pistol, with Duffey just springing off the mark, while the other contestants have not begun to rise from their stooping positions. The picture thus proves that Duffey did not start prematurely, although he wasted no time after the signal was given. It is moreover a striking proof of the perfection to which the American has brought the art of starting. The test was carried out so secretly that even the pressmen on the ground knew nothing of it, and the next morning's newspapers accused Duffey of anticipating the pistol. The fact has, indeed, only just leaked out.

COLOURING PRINTS.—Messrs. Peache and Co., makers of the "Cardium Colour Pats," write us, pointing out the suitability of these colours for painting prints, as described in the article on this branch of work, which concluded last week.

PHOTOGRAPHING Forts.—Dr. Franklin Clarke, an American medical man, has been arrested at Kingston (Jamaica), charged with taking photographs of the defences of Port Royal. Pictures of the principal forts were found on him.

SPY Mania at Plymouth.—While taking photographs from the top of Bull Point, near Plymouth, one day last week, a Bristol lay preacher was suddenly interrupted by an excited constable, who seized his camera, and, in spite of his protests, marched him off to the police station. When he arrived there he was closely questioned as to his antecedents and reasons for wishing to take photographs of Plymouth. The preacher's answers proving satisfactory, the authorities apologised for arresting him as a spy, and, in compensation for his detention, gave him permission to return to Bull Point on condition that he took only a snapshot of the bridge. A constable accompanied him to see that this condition was fulfilled.

"THE BROMIDE MONTHLY."—The familiar green-covered little booklet issued by the Rotary Photographic Company, of 12, New Union Street, Moorfields, now appears, with the addition of a subtitle "Photo Notes." The need of this more descriptive indication of the contents of the publication will be appreciated when it is seen that P.O.P., carbon, tissues, films, a process of tri-colour photography—all products of the Rotary Company—are dealt with in its pages, in addition to bromide work. A copy of "The Bromide Monthly and Photo Notes" will be sent free for 3d., or the annual subscription is 2s. 6d.

THE Northern Photographic Exhibition.—The two-thousandth visitor to the Northern Photographic Exhibition, at present being held in the Leeds City Art Gallery, has passed the turnstiles. His name is Mr. F. Gilbert Baker, of York, and he selected the guinea picture "Harvesting," by F. G. Issott. We are also informed by the hon. secretary that several inquiries have reached him from non-exhibitors for a copy of the exhibition catalogue, which, as we have previously mentioned, is a very fine production. These inquirers will be pleased to hear that 1s. 3d. will ensure them a copy by return of post from Mr. F. G. Issett, 62, Compton Road, Harehills, Leeds.

THE Altrincham Photographic Repairing Company, of Lower Grafton Street, Altrincham, have sent us particulars of the special

ilities they possess for the repair of anything and everything employed in photographic practice. For several years this firm has been making photographic specialties and sundries for the trade, and have now further extended their sphere of usefulness by organising a repairing department replete with the latest machinery and tools for dealing with shutters of every make and description, cameras, plate-holders, studio accessories, changing-boxes, printing frames, lens fittings, tripods, camera brass work, apparatus for amateur photography, etc. Photographers possessing damaged apparatus should write for particulars.

The New Zealand International Exhibition.—Particulars of a great international exhibition organised by the Government of New Zealand are to hand. It is to be held during the summer of 1906-7 (corresponding to our winter) at Christchurch, Canterbury. New Zealand, and all the nations of the world have been invited to participate. The object of the exhibition is educational, and it is intended to demonstrate the resources and possibilities of the colony as one of the world's food-producing factors, its vast mineral resources, and to draw attention to its splendid scenery, thermal wonders, and also the exceptional opportunities offered to sportsmen. Further, to bring under the notice of the more industrial nations of the world the great field the colony offers as an outlet for enterprise, and for the use and consumption of all manner of up-to-date appliances, manufactures, etc.

The Salon prospectus of the Photographic Society of India has been sent us. It is a striking little booklet, and contains particulars of the salon to be held from January 15 to 31, 1906, at the Club Rooms, 40, Chowringhee, Calcutta. The exhibition is conducted to work by the members of the society and amateur photographers resident in British India.

The September number of "The Optical Lantern and Cinematograph Journal" will be enlarged. New and important features will be introduced, but the price (3d. monthly) will remain the same.

A well-illustrated and brightly-written little guide to Ryde, Isle of Wight, has been sent us. The photographs from which the half-tone illustrations have been made are by Matthews and Son, photographers, of Ryde, and they give an excellent idea of the extent and attractions of this bracing watering-place. Any of our readers contemplating a holiday in the Garden Isle should apply to the secretary of the "Ryde Association for Advertising the Town and District," 33, St. John Street, Ryde, I.W., for a copy of the book.

Merk's Annual Report for 1904 reaches us from 16, Jewry Street, London, E.C., and we are glad to find it produced on the broad lines of its seventeen predecessors. Merk's Report, let it be said for the benefit of those who are not acquainted with it, is a thoroughly abstract of progress in therapeutics, and contains a brief account, with a reference to the original source, of every notable new fact in the application of drugs, whether these be the special products of the great Darmstadt firm, or an everyday preparation. The Report runs to 250 pages, and is sent free to medical men and others.

We hear from Bournemouth that Captain Day, V.D., of the 6th B.H.R. was recently entertained at a complimentary dinner at Hôtel Métropole, when his thirty-six years' service as a member of the Citizens' Army was suitably recognised. Mr. Day is a well-known photographer and an old subscriber to the B. J. An article on pictorial work appeared in the "Studio" recently.

The Sunderland Photographic Association will hold their second exhibition March 19 to 24. Further particulars will be announced later. W. E. Kieffer is the hon. sec., and his address is Stirling Street, Sunderland.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- E. Thompson, 19, Hounsfeld Road, Sheffield, Yorkshire. *Photograph of the King and Queen with the Marquess of Londonderry in Carriage at Sheffield, July 12, 1905.*
- T. Dann, 88A, Brighton Road, Redhill, Surrey. *Photograph of Tunnell Road, Reigate, A Peep at Reigate Priory, Batts Hill, Redhill, Reigate Castle Gateway Philanthropic Lane, Redhill, Church Walk, Reigate.*
- J. Bailey, 73, Shirley Road, Southampton. *Photograph of Capt. Chas. Barr, Defender of America Cup, and Winner of the Kaiser's Cup, 1905.*
- A. Simmons, 253, Westminster Bridge Road, London, S.E. *Two Photographs of Capt. W. F. McCann and Mr. W. H. Philp.*
- E. L. Pick, Earncliffe, Blundellands, Liverpool. *Two Photographs of S.S. "Irrawaddy" on the Rocks at the "Stack," Caldy-Man.*
- W. Brown, 9, Gilmour Street, Paisley. *Two Photographs of the Rev. A. G. Fleming.*
- H. Comer, Oxford Street, Oakengates, Shropshire. *Photograph of the Kangaroo Shot on the Wrekin on July 19, 1905.*

COPYRIGHT.—1. A party engaged a furnished house for a month; is it right for me to photograph the house and party in front without the owner's permission? 2. If I take a view and copy-right the negative, could another photographer take same view from same spot, and sell the copies?—W. H. R.

1. Certainly you can do so. 2. You cannot prevent another photographer from making and using a negative of the same scene.

A. J. HARRIS.—For France: "Photo-Revue, 118, Rue d'Assas, Paris. For Germany: "Photographische Chronik," Wilhelm Knapp, Halle a/S Saale, Germany.

N. BARRY.—"A." In our next.

WORKING UP.—My employment is to "work up" the negatives in weak places, such as putting in detail in shadows, highlights, strengthening, etc. I am familiar with using matt-varnish, and rubbing on blacklead to keep weak parts back, and reducing too dense portions with spirit; but 1. I should be glad to know if there is anything else which can be done. I have been told that ether is used for some purpose, but do not know what. Can you tell me this? 2. Also, in looking over some negatives done by others, I see some of the skies matt-varnished and blacklead to a density which I can by no means attain in the same way. Where there are many trees in a negative requiring blocking out, it is made solid with opaque to an inch or so of the foliage and then varnished and worked on with blacklead. The lead is put on so densely that the line where the opaque ends does not show, and then is softened down as it reaches the foliage. This gets a much softer effect than going round the tree tops with opaque. I have tried mixing the lead with gum, but this does not get the same effect either. The only way I know of is to rub on the lead as a powder, and in this way I cannot get it nearly dense enough? 3. Also can you tell me of any other liquid to be used for writing names on negatives than Indian ink; and 4. what sort of pen I should use? If you can help me in these matters, or with any

other hints I shall be very much favoured, as the work is new to me.—I. A.

1. Use tripoli powder with the spirit, which should be rectified (98 per cent., i.e., B. P. quality), or absolute alcohol. Ether can be used, but is inferior to rectified spirit. 2. First varnish the negative with collodion, and work over parts required with best electrotypers' plumbago applied on cotton wool. Then varnish with the following, viz.—seed lac, 2 oz.; sandrac, 2 oz.; oil of lavender, $\frac{1}{2}$ oz.; castor oil, 1 oz.; alcohol, 40 oz. Digest together. Allow to stand, then decant, and filter. Apply hot, bake well, and when cold matt the surface by applying powdered resin with gentle friction. Electrotypers' plumbago can then be applied with cotton wool (or preferably by means of an instrument called a tint stump) of such a density as to give complete opacity if desired, providing the sky itself is fairly dense to begin with. 3. Indian red, suitably diluted with water, or "Photo-pake" answers equally as well or better than Indian ink. 4. A fine red sable brush should be used for writing names on negatives. You will get a good deal of information on this kind of work from "Retouching," by Arthur Whiting. 1s.

A QUESTION OF NOTICE.—I am an assistant, working seven days a week and paid weekly on Saturdays. My employer on Monday gave me notice to leave, not specifying when. Can you inform me if the notice takes effect as from Saturday next, or am I bound to leave next Saturday.—ASSISTANT

You can claim a full seven days' notice, commencing from any day. That is, you can claim wages up to Monday next.

FLASHLIGHT.—I should be greatly obliged if you could give me any information on the construction of a flash or other artificial light for outdoor work, head and shoulders on victoria size ferrotype dry plates. I have no gas or electricity available, and want something to use when it is getting dusk.—W. ELLIOTT.

Any good blow-through flash lamp burning pure magnesium powder will answer your purpose. The Todd-Forrett lamp is a good example. It is obtainable from most dealers, and, in any case, a lamp of this sort will give more satisfaction than a home-made one. If it is desired to burn flash mixture, a lamp of the Maloni type or the "Tress" flash lamp will be found efficient. See our advertisement pages.

PHOTOGRAPHY IN SWITZERLAND.—Could you kindly inform me if it would be advisable on a holiday tour in Switzerland, to use isochromatic plates with a screen; and if the light there is much faster than in England? And (2) could you tell me of a good iso-flat-film; and one preferably that could be used for single transfer carbon printing?—SALVEPT

1. If Alpine photography is intended the light will be found appreciably better than in England. In the valley and on the lakes, however, similar conditions will apply as for exposure in this country. Isochromatic plates and a screen will, of course, give a more correct rendering of a subject in which snow, clouds, and dark green foliage predominate; but for snapshot work in the towns and villages a good rapid ordinary (non-iso) plate will be useful. 2. Kodak, Ltd., and Ilford, Ltd., both issue a good iso flat film. That of the former is the so-called "Kodoid" plate, that of the latter a stiff celluloid film, and there are several others on the market.

T. HARRIS.—You have misread our answer, the ammonium chloride is not washed out. When you have mixed the emulsion as we gave it, it is coated without any washing just as it is. It is neither pressed through canvas nor scored with a fork.

RETOUCHING (M. A.).—1. The quality of the retouching is not very good, but could be improved by your taking lessons. 2. The print is a very good example of carbon work.

RETOUCHING (Ambitious).—1. The preservation of the likeness on your best point, but the touch is mean, too insignificant and minutely stippled for such a subject, and your general effect is hard and unsympathetic. You also work too horizontally across the face—not allowing for the natural curves and undulations of the features. This means defective modelling which you should closely look to and improve upon. 2. As a general assistant you might ask from 30s. to 35s. per week, but it is difficult to quote probable salaries as we are not the employers. 3. Making yourself proficient in B. and W. finishing would greatly increase your value, and all operators and retouchers might well make this a side study, instead of sitting on the fence contented with their present knowledge, especially when competition is so keen and firms so exacting.

MOUNTING BROMIDE PRINTS.—I should be very much obliged for any hints you can give me re the mounting of bromide prints. I soak them for a few minutes, and lay them down in a pile on glass, blot off superfluous moisture, and apply starch paste, then lay them on mount and rub down under blotting paper. I find, however, that the prints are very liable to damage, from sticking to the blotting, which brings away pieces of the film. The hot weather is, no doubt, answerable for some of the trouble, although the same thing occurs, to some extent, at all times. I may add that I use alum in the fixing bath during this hot weather. Can you help me?—SIGMA.

Why not mount them dry? It is not only easier, but cockling of the mount is prevented. After washing, blot off the superfluous water with blotting paper and lay out to dry face upwards, or dry quickly by the aid of methylated spirit. When the prints are dry straighten them out by passing under the edge of a straight ruler and trim them. They can now be mounted by smearing a small quantity of mountant containing little moisture, such as Higgins, over the backs, and pressing into contact with the mount (which has previously been marked with pin-pricks exactly where print is to be placed). The mounted prints can now be placed under pressure, in a copying press, for instance, and will come out perfectly flat. An alternative method, much advocated by pictorial workers, and very suitable for many subjects, is to apply a very little strong adhesive, such as Seccotine, to the back of the print at the top edge only, or even at the two top corners. This is sufficient to firmly hold the print in position, and the fact that it is not stuck down all over is not regarded as detrimental to its appearance.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

What is Carbon Surface?

Papers are now on the market prepared with silver salts, the results with which closely resemble carbon pictures or possess a "carbon" surface. One with a hypercritical turn of mind might well be inclined to ask the above query. What is a carbon surface? As a matter of fact it may be anything between that of the roughest of rough drawing papers, and that of the highest "enamelled" silver prints. If an ordinary carbon print be developed on a very rough drawing paper it will have the surface and texture of that paper. If on an ordinary surface drawing paper it will possess the surface of that paper. On an ordinary matt paper it will have a more or less matt surface, and if produced on the usual single transfer paper it will have a semi-glossy appearance. We have here been speaking of the single transfer method of working the carbon process, but turning now to double transfer, if the picture be produced on a matt surface—say ground opal glass—which, by the way, is now so largely used for the purpose—we get in the finished picture a matt surface; and if the glass is previously coated with collodion a rather less matt picture. If instead of employing a ground glass as the temporary support we take the ordinary flexible support of commerce we get a surface very similar to that of albumen paper, and it is this surface which is what is usually understood to be the typical "carbon surface." If the picture be developed on plain glass, previously coated with collodion, and then transferred in the usual way, it will have a surface equal to that of a P.O.P. print that has been squeezed on to a ferrotype plate and stripped off. But if prior to the stripping, and while the print is still moist, one or two thicknesses of double transfer paper be squeezed upon it and allowed to dry before stripping, à la Lambert's "chromatype" process, we get a surface equalling the

highest enamelled silver print. Indeed, with those who are *au fait* with the working of the carbon process, this is the simplest way of all of producing highly enamelled pictures. Seeing the great variety of surfaces there is in the carbon process, the query at the heading of this paragraph is not so very hypercritical after all. It is certainly a high compliment to carbon that we are witnessing the production of silver papers yielding prints which closely imitate the peculiarly subtle quality which characterises a carbon print.

Process Blocks.

We have often called attention to the opportunities which arise for the professional photographer to turn to his own benefit the increasing use of the half-tone block in commercial life. It may be taken for granted that the final destination of a very large proportion of work done away from the studio is the printed page, and there is no reason why the photographer should not contract for the whole job while he is about it. Photographs of a factory, of manufactured articles, of an hotel, or a man of business in his office are wanted in almost every case for circular or catalogue purposes, to which final form the half-tone block is the natural, because the cheapest, route. Of course, no one will counsel a photographer to add a photo-engraving shop to his establishment, but there are photo-engravers who make a specialty of photographers' orders, and place them in a position to secure this class of business.

Resittings.

Referring to an "Ex-Cathedra" note last week, a correspondent writes asking what is the London rule with regard to the number of resittings given before an extra charge is made for them? As the query is one that is not infrequently put to us we deal with it here instead of in the usual "Answers" column. Our correspondent, in effect, complains that sometimes customers are taken three or four times, allege the portraits are not good, but fail to return the unfixed proofs. He suspects the prints have been toned and finished by one of the family who he knows is an amateur photographer. In reply to his query, and others we at times receive, we may say there is no set rule with London photographers on the subject. Most photographers are anxious to give satisfaction to their customers with a view to further business. If the first sitting is not satisfactory, although the photographs may be good, they are pleased to give a second, or even a third; but, of course, there is a limit to all things. One thing might be enforced in the case of some sitters, namely, that all proofs whether toned or not must be returned, or paid for at the price of finished pictures, before the resitting can be given. This would ensure the return of the proofs. If the proofs were branded in the way we suggested last week, they could not be utilised

in the manner the correspondent suspects, and, as we have said, could give no possible offence to the customer. If the sitting is not paid for at the time and the proofs are kept, the customer can be sued in the County Court for their value as finished pictures. We have seen on some reputable photographers' prospectuses such words as "satisfaction guaranteed." With this the photographer places himself in a somewhat awkward position with regard to captious or unreasonable sitters. It implies that he must retake the portrait as many times as the sitter desires until he or she is satisfied with it, or he cannot recover payment for it. We have always looked upon these words as being quite a mistake on a photographer's prospectus.

Applied Knowledge.

There is a wonderful difference between the work of the man who is apt to apply his knowledge and the man who simply works by rule of thumb, and according to some note or hand-book he may have for reference. Let us recall a couple of instances of what we mean. The first is the case of an experienced enlarger and carbon worker, accustomed to the production of enlarged negatives by daylight in the camera. Circumstances arose in which it was necessary for him to use an artificial light enlarger, focussing on a white surface and fastening the plate in position with drawing pins on the easel. Plate after plate was exposed, and found foggy and flat, and the method of working was condemned as useless. A moment's reflection, a moment's comparison with ordinary dry plate conditions would have revealed the source of failure. Either the plate should have been backed, or the easel should have been covered with a black material, the focussing being done on a white card easily removed. The explanation is so simple that the difficulty appears ridiculous. There was a lack of fertility of resource, in a word a lack of thought. The second instance was that of an experienced worker, who, in developing with pyro-ammonia a plate in the dark room, noticed almost as soon as the developer was poured over the plate inky patches in the white porcelain dish. A second or two of thought and out went the developer and the plate was flooded with water. The thoughtful worker had applied his knowledge at once. Ferrous oxalate developer had been used in the room, and had been splashed into the dish. The pyro with the ferrous oxalate at once produced ink. We do not remember how it was the dish had not been washed, but we give the incident as we witnessed it in the worker's dark room.

Tracing Defects.

It is, of course, much more difficult to trace the reason of defects and failures when these are brought away from the place of production. A negative or batch of prints sent to us for diagnosis may show some defect which could be produced in many ways. Only a day or two ago some quarter plates shown to us possessed curious markings which at first sight looked like melting of the film due to the heated condition of the dark room atmosphere. On careful inspection it was found that this was not the cause. Examination with a glass suggested that the plates had been pressed together and the gelatine squashed. This, on inquiry, was found not to have occurred. Then it was ascertained that the plates had been placed after development in an alum bath and with a very hurried swirl into an acid fixing bath. This appeared to be the cause of the markings, though without making a number of tests with the same plates and solutions it is not possible to pronounce definitely. We recall the case of a firm of plate-makers, one of whose clients got mysterious markings on his negatives. A

chemist from the firm went down, and with fresh plates got the same markings. Plates developed at the factory showed no marks. It was eventually found that the warm solution of sodium sulphite and citric acid was poured into the pyro bottles, and on returning the then pyro solution to the stock bottle, the wax employed for luting in the pyro corks was softened, and carried into the stock bottle and this wax or grease was the cause of the trouble.

The Celluloid Hair-comb.

In another column is reported still another case in which the celluloid hair-comb has proved disastrous to its feminine wearer. The circumstances are almost exactly those of one of the German incidents of the same character which were mentioned in our pages some months ago. The lady, wearing the comb half embedded in her hair, was kneeling before the fire, when the comb caught fire and caused damage, assessed by a jury at £50. As we pointed out in connection with the previous cases, it is remarkable that celluloid accidents should be practically limited to hair-combs. Despite the enormous use which is made of celluloid in photography scarcely a single instance of an accident caused by it is known, and, indeed, in the case of a roll film the double coating of gelatine is a protection against accidental ignition.

A South African Exhibition.

Particulars to hand from South Africa tell us that great preparations are in progress for holding an International Photographic Exhibition at Cape Town in February next, and the Cape Town Photographic Society will spare no efforts or expense in making it a big success. Last year their exhibition was a notable one, and spoke volumes for the enthusiasm of our colonial friends. Now that the country is getting settled into a state of peaceful prosperity after the strenuous times of war, great things may be expected for the exhibition of 1906. The School of Art housed last year's show, and although the rooms were large and suitable, the exhibits were crowded for want of space, and the general effect suffered accordingly. The New City Hall has therefore been secured for next year, and three times the amount of space will be available, while a couple more large rooms can be added if necessary; all the space being thoroughly well lighted, both for day and evening work. The society is working in the right spirit of altruism, and with a loftiness of purpose as characteristic of pioneers as it is unfortunately conspicuous by its absence in most of the photographic associations of this country. The executive of the Cape Town Society intend their exhibition to be a big success, not financially, because they have not the population to draw on for an audience, and all exhibitions of every description held in the colony have been financial failures. With the certainty therefore of a big deficit in view this band of workers are prepared to dip their hands in their pockets for the furtherance of their favourite art, and for the sake of the educational benefits that will undoubtedly result from the opportunity of seeing good work from different parts of the world. What English society would venture to this extent? The conditions are different certainly, but still the right spirit is needed before an undertaking of this sort can be contemplated, and we wish the Cape Town Society and its exhibition all the success they deserve.

Picture Postcards of Convicts.

During the past week complaints and interviews have been published in the daily papers on the subject of the photographing of convicts in English penal establishments, for

the purpose of reproduction as picture postcards, and on Monday attention was called to the matter in the House of Commons. The entire question appears to be causing considerable perturbation in the minds of more than one correspondent. A writer to the "Daily Mail" asks, in reference to some of these snapshots of the convicts at work, taken at close range:—"1. Why do the authorities allow such photographs to be taken? 2. Why are shopkeepers allowed to publicly display photographs of men who are already paying the full penalty of their crimes? 3. Why do the Post Office authorities permit cards bearing what are clearly "improper" pictures to be sent through the post?" The public generally holds the comfortable belief that the identity of these men is completely lost from the moment they cross the threshold of prison, and that their doings are kept as secret as stringently enforced rules can make them. Investigation on the part of the "Daily News," however, dispels this belief, in spite of a communication from the Governor of Dartmoor Prison (where the pictures were taken), who states that "every precaution is taken against photographing convicts," and that he does not believe the statement that picture postcards of the men at work are on sale. An interview with the heads of the Campbell-Grey firm of Cheapside, who have issued "interiors" and "working scenes" of every important prison in the kingdom, discloses the fact that there is practically no restriction, except that photographers are precluded from obtaining special posings or groupings. But that condition is set forth in the permit, and beyond seeing that it is not infringed the governor of a prison is practically powerless to interfere. The whole thing rests with the Prison Commissioners, and they insert a further condition that proof sets of pictures shall be submitted before printing any series. In due course the proofs come back marked either "These pictures may be published" or "These pictures must not be published."

Convicts and the Camera.

The other side of the question is shown when we hear that not only do the convicts enjoy the operation of being photographed, but that in many cases the great difficulty has been to keep prisoners' faces "out of the camera." There is a clearly understood rule in all prisons that when photographers appear, no convict is required to remain at work, or even in his gang. Probably no man with a sense of shame or self-respect would care to appear in a picture which he knew would be published broadcast, but that a certain amount of unauthorised snap-shooting of the men at work, entering and leaving the prison and quarries, etc., is undoubtedly done is evidenced by numerous correspondents resident in the vicinity of the more notorious penal "castles," who have sent specimens of photographs taken "under the very eyes" of the chief officials. From a purely social point the question to determine is whether the publication of such photographs is in any form desirable. A leading sociologist sums up the situation in the "Daily News" when he says: "The present-day rage is to get to know what is done everywhere. A snapshotter would like to get in at a Cabinet Council, and most people concerned with photo work would pay big sums for a lot of the impossibles; but it is simply absurd to talk about infringing privacy or hurting these people in convict prisons by photographing them."

The Rotary Photographic Social Club.

On Saturday last another of those interesting functions in the progress of the English photographic trade was performed at Yiewsley, West Drayton, by the directors of the Rotary Photographic Company. The

tendency in these democratic times is for the employer to come into close touch with the employee, and the gift of a well-found social club to the workers in this flourishing concern amply demonstrates the policy of mutual give-and-take voiced by Mr. Bealtz, the chairman. The company has grown in England, from very small beginnings five years ago, to an extremely prominent organisation with over 300 employees, and there is no doubt that in a firm of this sort as much of its success depends on the whole-hearted support given by the employees as on the exercise of abilities necessary for the work in hand. The policy of the directors, therefore, has been to show that the interests of employer and employed are identical, and Saturday's function will go far to cement this feeling.

ORTHOCHROMATIC RATIOS OF PLATES.

THE letter which appeared under the above title in our issue of last week is not quite so explicit as one would wish, but as it calls attention to a subject which is becoming of increasing importance, we take the opportunity to answer what we imagine to be the objections to the system adopted.

Dealing first with the standard light, it is obvious that the nearer this latter can approach daylight in spectral composition, the more valuable will be the numbers obtained, because the conditions more nearly coincide with those of practical work. In their original paper dealing with the "screened acetylene light" Messrs. Mees and Sheppard state that it is approximately diffused daylight, and that plates tested by this light and daylight gave identical inertias or the same speed. The sole purpose of the "screening" is to correct the preponderance of red, yellow, and green in the acetylene light, and if this were not done a totally erroneous reading would be obtained, in proof of which we may use the *reductio ad absurdum* argument, and state that the readings obtained on ordinary and colour-sensitive plates by the so-called monochromatic sodium light would then be the true speeds of the plates.

The method adopted by Mr. Kenneth Mees is that proposed by Dr. Eder, and we must confess that we cannot see how our correspondent can support his contention that "this is not anything like the real value of their relative sensitiveness to blue and yellow light as transmitted by these screens."

We reproduce herewith the two diagrams given by Dr. Eder of the absorption curves of these filters, the wave lengths of light being abscissae, and the extinction coefficients being drawn as ordinates.

Fig. 1.

Fig. 1 shows the absorption of the blue filter, naturally represented by black, and above is shown by the dotted curve the spectrum sensitiveness of an ordinary plate to sunlight, a prismatic spectrograph being used. If now the dotted curve be folded down over the absorption curve of the filter, there will be found almost complete coincidence.

Fig. 2 shows the absorption of the yellow filter,

Fig. 2.

and above is the characteristic curve for an erythrosine sensitised plate. It will be seen that here also the absorption of the yellow filter coincides very closely with the blue and violet sensitiveness of the plate—that is, with its “ordinary” sensitiveness—and it transmits all light from E practically undiminished.

To put the matter very baldly, Eder’s blue screen determines the “ordinary” sensitiveness of the plate; that is, it determines the sensitiveness of the emulsion were it not orthochromatised, and the yellow filter tells us what has been added on to this.

We are not quite clear as to what our correspondent means by “the relative brilliancy (regardless of colour) of the light transmitted by these two liquid filters.” If

he refers to the absorption or extinction co-efficients of the filters, then Dr. Eder has given these (*Beiträge zur Photochemie und Spectralanalyse III. Abtheilung, p. 127*) for every eight wave lengths, to which we must refer him for we cannot see the general practical value of the and therefore refrain from reprinting them.

If, however, our correspondent refers to visual luminosity—and we gather that he does mean this from his penultimate paragraph—the proposition is absurd. To obtain equal brilliancy we must either enormously reduce the yellow or enormously exalt the blue, and having done this, we should have to correct the results by a complicated calculation to bring the factors obtained into line with the conditions of practical work. Whereas now, knowing,

the ratio of $\frac{\text{blue sensitiveness}}{\text{yellow sensitiveness}}$ any practical worker who

also knows the ratio of $\frac{\text{visual luminosity}}{\text{photographic luminosity}}$ can at once

adjust a colour filter to give his ideal negative. Without being unduly egotistical we may safely claim that we have been the first of any photographic journal to give actual test results by a generally accepted system and until some one will settle once for all the debatable point of colour luminosity versus colour contrast we are convinced that the system we have adopted of telling in definite terms what is added to the ordinary plate by “orthochromatising” is the most satisfactory.

ON THE DISPLAY OF PICTURES.

A REALLY good indoor exhibition is essential to photographers of all grades. Showcases or window displays should induce people to look round and inquire prices, but however good they are, they will be quite wasted unless the showroom is tidy. Specimens should always look fresh, and the premises smart, if business is to be persuaded.

Decorating Materials.

The reception and exhibition rooms (frequently one and the same) should be decorated in the most tasteful manner one’s banking account will allow, and as the last requisite is somewhat elastic, nothing but general details can be given. The modern method of using deep frieze, picture rail, and self-coloured wall covering makes an excellent background for pictures. When it can, the used art-canvas is the material par excellence for walls, on account of its perfect matte surface. Any large area of wall space can be broken up by using stained wood uprights. A dark green paper or canvas looks well, but we consider dark brown paper as satisfactory as anything. The colour harmonises perfectly with oak moulding, and does not clash with gilt frames.

Specimens for the Reception-room.

As for specimens, every gallery should, of course, have a few at least of its best pictures enlarged for the walls, the process depending a great deal on the class of people catered for. With a good receptionist, money spent on these specimens will soon bring a good return. A beautiful face or attractive pose framed up in good style pulls orders. If you cannot do better, bromides will pass, but good carbons look best, and add distinction to the establishment. We like good, rough carbon prints—sepia or red—on etching papers, but, unfortunately, the great Public (capital P) will not look at them, and as all your efforts are towards one end—that is, to please them—their peculiarly stubborn likes and dislikes must be studied. Even yet the great majority will not look at anything rougher than the most delicate matte. Their highest appreciation is showered on the beautiful smooth things on opal that are “so clear” and show “that beautiful lace.”

Processes and the Sitter.

To make a slight detour, how on earth can the great majority of professionals be expected to work up to art standards when their clientèle insist on having nothing but what they call clearness? How, again, can one show skin texture when the sitter demands to be retouched out of all recognition? The question of tone values, too. Why, if you chance to show them good tonality for concentrated indoor lighting, one immediately hears the remark that they are not niggers. All this is, perhaps, beside the point, but it is no fancy picture simply results of reception-room experience with well-educated and, presumably, artistic customers, and is introduced merely to point out the necessity of not going too high for your public but show them what they want, and let art go hang.

The Finishing of Specimens.

Whatever process the specimens are executed in, the finish must be of the best. If you put the work out to tradelargers it is just as well to tell them exactly what you want. Many photographers of the cheaper class have peculiar ideas on working up, and think gummed-up shadows and Chinese-white high-lights in the best of taste. This being the case, it is only natural that at times photographers who know better get this style of work sent to them, and blame the enlargers for what indirectly is not their fault.

Mounts and Frames.

The method of mounting and framing to be selected requires care and consideration. Usually there are several factors to be taken into account, but if the walls have been treated in a subdued fashion, in professional work only the print itself need be consulted. Warm-toned prints are easier to frame effectively than cold plats, or bromides, and may be framed with mounts or close up. The latter prints should usually be mounted. For most work of any size, framing close up is the handiest, especially if the picture happens to be a large head. Full lengths, perhaps, are better with mounts.

As a general rule, we prefer the mount to harmonise with the print, and usually with the frame also. Especially is this

the case with black and white prints, which should only be mounted on white or black or any of the numerous shades of grey between. We consider any *positive* colour near a grey tint an abomination. Warm-toned prints may harmonise or contrast, but usually mounting in harmony is to be recommended. Framing is a question best left to the discretion of the photographer. Mouldings may be divided into oaks, gilt, and composition. The latter description are not good, and should be avoided. Oaks are the most generally useful, as they can be stained any colour and made to suit any prints.

Gilt Frames.

Gilt frames are still asked for at times, and even yet many people consider them the height of taste. Were it not for this, we should recommend them to be banished from the showroom. The advantages of oak over gold are not only in the question of appearance, but also in cost and utility. Whereas an oak frame improves with age, gilt ones soon deteriorate and look tacky.

With a little tact one can usually switch a customer off these gaudy and photograph-killing frames, but sometimes gentle persuasion is of no avail, so the customer must be unmoved, and it behoves the photographer to do so with as little damage to his own work as possible. Now, although old leaf is death to most monochrome work, there are a few things it will suit fairly well, and those few things are:—For framing close up, sepia carbon on opal; for framing with mount, any carbon but black. The mount in this last case must be cream or vellum, to carry out colour of frame. Framing close up in gilt is particularly difficult, and after many experiments we think nothing but a sepia print will do (preferably a large head, and printed solid, not vignette). The smooth surface of the opal appears to agree with the superne character of the frame.

The actual arrangement on wall depends to a great extent on the space at one's disposal.

Arrangement of Wall Specimens

The hanging of the frames on the wall should receive the greatest attention. As only one room is to be used, and that, presumably, is papered in an unobtrusive and neutral fashion,

the wall paper, as mentioned before, need not be studied.

The frames, mounting, and prints on each wall should be well varied in colour, shapes, and texture, but not so much as to clash with one another. Avoid symmetrical arrangements, as a rule. At times a symmetrical whole with unsymmetrical parts is not bad. Do not get the tops and bottoms of a line of pictures in a straight line; neither, in most cases, should the sides of two or more frames form a straight line.

Avoid Overcrowding.

This is advice all professionals should take to heart. All the best reception-rooms I have been into lately have only three or four beautiful and, in many cases, marvellous specimens on each wall. The effect is most artistic, and gives one a very different idea to that of chaos so often associated with the usual professional display. Remember, too, that although variety is required, it should be variety in unity. Positive colours with positive colours, strong prints with dark backgrounds, with other strong points. Not a red-chalk cheek by jowl with a weak platinotype, or a "Rembrandt" effect next to a print of "sketchy" handling with a white ground.

Concentrate the Interest.

If you have large walls, then it is as well to concentrate attention on each lot of prints by dividing the walls into large panels, by using hangings of art silk or canvas, wood uprights, or stencil designs, between each section.

If you go in for gilt frames, keep them separate and strictly to themselves. Nothing looks worse than oak and gold frames together. It is better to sky large heads and big pictures, keeping the small, delicate stuff on the line. Whenever possible, have the light in picture coming from same direction as the room is lighted from. The actual hanging with the modern picture-rail and hooks is easy. When nails are to be used, use "French" nails for the light frames, as they damage the wall less than the brass-headed variety. These latter are, of course, used for heavy work. Large pictures, especially those on opal, should be wired up or fitted with screw plates. Cord and rings are safe enough usually. When used, get drab cord, or some similar to the colour of paper.

"PROVINCIAL PRO."

OLD-FASHIONED NOVELTIES.

THERE is very little that is new under the sun. I was recently in a small village in the Midlands, and the only photographer had a sign and samples of "Midgets—the latest novelty." No doubt they achieved his purpose; they would be something new to his customers, and they would bring business. Occasionally a man does introduce a new idea, or make a real advance in photography; but usually novelty means merely a slight change of fashion or the re-introduction of some method already well known to the profession.

For the Individual.

The average man is not primarily an altruist. He is in business, first of all, for his own ends, and the betterment of the profession at large is only a minor question with him. Indeed, there still lingers, I am sorry to say, that old feeling of jealousy, which looked on the man "over the way" as an interloper, and felt that success could only be achieved at his expense. This feeling is not as strong as it was, and it will more and more fade under the healthy influence of the P.P.A. But the old struggle will remain, and it behoves each individual to do his best for the promotion of his own business. And so, although old-fashioned novelties may not be a help to photographers at large, they may help many individuals who are looking for something to give business a flip during a quiet season. It may seem rather unnecessary to repeat what

all photographers ought to know; but it is a fact that many of them know very little indeed beyond the workings of their own studio.

A Case in Point.

During the same visit to the Midlands I had a long chat with a photographer, who complained bitterly of the tightness of things. When I left him it was his intention to introduce a novelty, which he had learned from me. And that novelty was, of all things, reversed or Russian vignettes! And now for the folly of the man. He subscribed to the JOURNAL, because his father had done so before him, but his magazines lay unopened on a shelf. From some he had split the wrappers, but there were many in just the condition that the postman had brought them. If he had read them week by week he might not have introduced reversed vignettes, but he would in a short time have come across at least a dozen ideas, any one of which would have met his needs.

A Few Ideas.

Just to show that I am not exaggerating, I will mention a few of the simplest ideas, such as any man may at once see for himself. Most of my readers will smile at them, but every one is an idea, old as the hills, at which some photographer has jumped when I have first mentioned it to him. First, there is the mirror; after a run of full face bust pictures,

interspersed with an occasional "Rembrandt," try a picture of a lady looking into a mirror, by which a side face and a full face (reflection) may be obtained. Then older still—older than photography itself—there is the silhouette. Silhouettes always attract when placed in a show case, but they do not bring much business, especially in a cheap trade. But "semi-silhouettes," in which a certain amount of light is reflected back on to the figure, are worth running as a temporary novelty. Transparencies are a novelty which seem strangely neglected, for there is nothing more beautiful in its softness and richness of gradation than a good transparency. Everybody knows, or should know, that a beautifully soft effect may be obtained in portraiture by placing a thin sheet of mica or celluloid between the negative and the paper during a part of the printing. But why need I refer more to these everyday affairs, when there are so many similar hints in the back numbers of this magazine?

The Novelty of Difference.

The time is passed when there were no mounts except bevelled edge ones, intended for insertion into albums. Thousands of photographs are made nowadays which never see the inside of an album. And so photographers have varied the style of their trimming and mounting in a way undreamed of twenty years ago. How often we are shown "the latest thing in mounts." Some new pattern is placed on the market almost every week, and the fashion varies from year to year. And the mounts are for all varieties of trimming. It may be a circle, or a long narrow oblong, or a pronounced oval. Almost anything, in short, except the old and somewhat too square sizes. In some businesses masks of various weird patterns have been successfully used. More than one worker has made a market for passepartouts, the glass being selected from discarded negatives, and the rough edge of it hidden by the neat binding strip. And yet there are some photographers who still stick to the old line mounts and sizes exclusively: If it were a matter of considerable capital outlay there would be some excuse for this, but a very few shillings will suffice for a good selection of mounts—and brains must do the rest.

Locality and Weather.

When we visit the seaside we are offered portraits—usually tintypes—of ourselves, with some local view, including surf and a lighthouse, as a background. The idea of specialising

is sometimes a good one. I know one photographer who does a large trade among the servants in large houses. Now, I would have thought that the servants would wish to be taken in their best clothes, but he knew better. His reception-room is filled with samples of pretty women in snowy aprons and caps. If the uniform is not reproduced too chalky it looks well in a picture, and gives a certain amount of dignity to a portrait which otherwise might be commonplace. And the girls come in their uniforms to be photographed. The photographer told me the idea did not go well with the men. It is a good idea for some places. I once saw a show case filled with portraits of police constables. Near a big racing centre photographs of unmistakable "horsey" men might attract; along the river a display of men and girls in boating attire might draw some holiday trade where the conventional show-case would pass unnoticed. There are possibilities, too, in suggestions of season. Who does not know the snow picture, for which nothing is required beyond an out-door costume, an umbrella, a little cotton wool, and some spatter.

The Cruz of the Question.

The whole question hinges on the personality of the photographer. There are men who cannot rise to the occasion. There are many round men in photographically square holes. Alas, that it is so! "The way out" might be pointed by an angel, but unless the man availed himself of the offered opportunity the direction would be useless. The man must get there on his own feet. There are studios in existence which seem to have no single reason for success, and until the man uses his brains and abilities they will continue to court failure. Capital is not money saved in the bank; it is energy set to work to achieve results. Money is merely a convenient form of exchange; and if the right man has it, he can make good use of it, but if he has not got it he does the best he can without it. The photographer who is waiting for something to turn up is wasting the capital of his own energy. It does not need cash to put a little life into a stagnant business. Cash will not furbish up the show-case or remove a faded specimen; but a few minutes' work will do so. And energy steadily applied will improve the whole building, and will improve the quality and variety of the work. For there is brain energy as well as muscular, and a little quiet thinking out of a thing will often point the way to results. ALEXANDER BRADFORD.

THE WEEK IN HISTORY.

From Wet to Dry Collodion.

TO-DAY fifty-one years ago G. R. Muirhead, of Glasgow, described his experiments on preserving the collodion-plate for a lengthened period between sensitising and exposure. In this work he had been anticipated by M. Gaudin, whose labours I have already referred to several times, but he was probably unaware of what Gaudin had done when he, on August 4, 1854, wrote to the "Journal of the Photographic Society":—"I have been making a few experiments on the collodion process, and have found light acts almost as energetically on a dry surface as on a wet, and that if a plate be washed well in water (after immersion in the silver bath) to remove all the free nitrate, and allowed to dry, it will remain unaltered for a lengthened period, provided it be kept from light or any deleterious gases, such as ammonia, etc. When wished a picture can be taken on this plate, but before development must be dipped in the silver bath, and a photograph will not develop without the presence of free nitrate of silver."

Gold Toning Sixty-five Years Ago

On August 10, 1840, a paper was communicated to the French Academy of Sciences, in which a gold toning bath was introduced

into photography. This took place on almost exactly the first birthday of the art, for Daguerre's process was made known only on August 20 of the previous year. M. H. Fizeau, who worked out this method of gilding daguerrotypes, may thus be truthfully described as the father of toning processes, and, unlike all later photographs as the daguerrotype was, the process which he devised survived for many years; in fact, the present combined bath is a variant of Fizeau's original hyposulphite of gold, which was not, however, endowed with fixing properties. His description of the preparation of the bath may interest my readers. My translation is from the "Comptes Rendus" of 1840:—"One gramme of gold chloride is dissolved in half a litre of pure water, and three grammes of hyposulphite in another half-litre. The gold solution is then poured, little by little, and with constant stirring, into that of the soda. The mixture is slightly yellowish at first, but soon becomes perfectly clear. It appears to contain a double hyposulphite of gold and soda, with some common salt, which takes no part in the process."

Before treating a picture with this gold salt the surface of the plate must be made perfectly clean, and any kind of grease

particular removed. It should, therefore, be washed with more than ordinary care, the following method giving the most uniform success: The two surfaces and the edges of the iodised plate are dusted, and a few drops of alcohol poured on the dusted side. As soon as the alcohol has wetted the whole surface the plate is plunged in a dish of water and then placed in a solution of hyposulphite. The solution should be replenished for each exposure, and should contain one part of salt in fifteen of water. After washing is done in the usual way, except that more than customary care is needed to exclude dust. The object of the alcohol is simply to allow of the water running evenly over the surface of the plate, thus avoiding stains. A plate having been washed with these precautions it is a very simple matter to treat it with the "sel d'or." It is placed on the iron threads

of the dark slide, and sufficient of the gold solution poured over it to cover the surface completely. Heat is then applied below from a lamp, and the picture is then seen to clear up and assume great vigour within a minute or two. When this effect is visible the liquid is poured off and the plate washed and dried.

By this process silver is dissolved, and gold is deposited on the silver and on the mercury. With very different results, however. The silver, which, by its peculiar surface, forms the shadows of the picture, assumes a brown colour from the thin film of gold which covers it, and so the shadows are intensified. The mercury, however, by its division into infinitely minute globules, forms the light, and, its brilliancy being increased by amalgamation with the gold, the high lights of the picture experience a remarkable intensification. HISTORIOUS.

PHOTOGRAPHY AND NATURE.

"The camera is mightier than the gun" is a modern-day aphorism that has been given us by the endeavours of a few earnest workers, who have probably done as much as all the pictorialists put together in indicating the present position of photography as an educational factor. We owe to the Keartons, Pike, Reid, Duncan, Snell, Kirk, Bentley, King, and others the knowledge that one can be an ardent sportsman, and yet not take life. The desire of the sportsman-naturalist photographer is not to kill, but to perpetuate. By the aid of one of the most wonderful of modern discoveries we are one and enabled to peer into the lives, habits, and circumstances of the humblest specimens of the Creator's handiwork who people the land, and can study at our leisure all there is to learn about them in a manner that would have been impossible twenty years ago, or less.

Three New Nature Books.

These thoughts have been inspired by a perusal of three books, recently published, that lie before us:—

"Home-life in Bird-land." By Oliver G. Pike. London: The Religious Tract Society. 6s.

"Wild Flowers, Month by Month. In their Natural Haunts." By Edward Step, F.L.S. London: F. Warne and Co. 6s.

"Wild Birds at Home." By Charles Kirk. London: Brimley Hanson and Ince, Ltd. 6d.

The Camera as an Illustrator.

Natural-history work with a camera forms an epoch not only in the photographic world, but in the art of illustrating as well. Previous to the advent of the naturalist photographer, "natural histories" and sportsmen's books were embellished with drawings more or less inaccurate. These to a great extent have now been superseded by photographs from life, while a number of nature books similar to those mentioned above have been called into existence by the mere force of circumstances. The increasing popularity of this interesting phase of photography is probably inducing every year a larger number of people to take up the use of the camera purely for their own sake. Mr. Pike has made for himself a name in the world of nature-photography second only to the Kearton Brothers, and in his latest book this enthusiastic naturalist, so amply endowed with the gift of patient observation and great skill in the difficult art of bird-photography, has given us in "Home Life in Bird-Land" a fascinating account of the results of his researches into the ways of his feathered friends. He betrays an unaffected delight in his work that is contagious, and his descriptions of the birds he knows well go hand in glove with the beautifully reproduced evidences of his skill and patience with which the volume is embellished.

Bird Land.

The whole of the country is "bird-land" to Mr. Pike, and whether it be on the mountain-top or on the marsh, it matters

not to him. In fruitful meadows, on cold bleak moors, over fresh-running streams in dense, darkened woods, or among the eternal snows of the great silent Alps has he met his feathered friends, and in his own way portrayed them and learnt to know their ways and habits, so that he is here able to describe them so delightfully.

The Bird-Photographer at Work.

The book teems with amusingly written accounts of the incidents and accidents that occur in the pursuit of bird photography. Mr. Pike, when stalking a watchful little grebe, tells us:—"As I sit in my tree-shelter a hundred little flies are around; and, in spite of a pipe of strong tobacco, they refuse to let me alone. They are biting my face and hands most vigorously, but this is just one of the little inconveniences a bird photographer has to bear. It is but one, however, for when I went to my camera a few minutes ago, I found a spider had commenced to build its interesting web in front of the lens." Again, when seeking for the home of the tufted duck in a large osier bed, the approach to which was a series of deep ditches full of black slime, the photographer, after long waiting in a cramped position, exposed a plate. Then, "when this was accomplished, one of those little incidents happened which, if they afflicted anyone but a bird photographer, might help to turn the hair grey; my slide in some way opened, and my plate was spoilt. At this point I heard a cry behind. My companion had slipped while jumping from one osier bed to another, and was clinging with hands and knees to the osier, which, gradually bending with his weight, was lowering him into the unpleasant black slush beneath."

The Sparrow.

Mr. Pike has a good word to say for the sparrow, and regards the little brown bird as a most misrepresented individual. He asks the question, "Is the sparrow a criminal?" and answers it very effectively in the negative. He decries the work of sparrow clubs in no unmeasured terms, and, with the true instinct of the naturalist, proves what he says about his little friend to be true, and asks us to respect him for the vast amount of good he does, to forgive him for his few destructive habits, and never grudge him a fair wage for genuine services rendered.

Some Practical Hints.

As regards the practical side of the work, our author describes in the last chapter his "bird-land" camera, which is of the long extension reflex type, with focal plane shutter and lens working at $f/4.5$. A telephoto attachment can be used with this occasionally, and with this outfit it is not necessary to get so close to the shy sitters. In photographing a bird the size of a rook one may even be twenty yards away and still secure a fair-sized portrait. Mr. Pike says:—"It is always better, I think, when photographing a sitting bird, to stop the lens down and give a

longer exposure, and I have also found, in the case of restless birds, that it is of advantage to have a shutter which makes a slight 'click' when open, for, however disposed the bird may be to move about, on hearing the opening of the shutter it will remain still to listen. Thus the shutter may be kept open as long as the bird stands still, or until the necessary exposure is given." Space will not permit of further extracts from this delightful book, which will be warmly welcomed, we have no doubt, not only by the special class of naturalists, but by all who love birds and their haunts.

Flower Photography.

A different type of nature photography is treated of by Mr. Step in Vol. 1 of his "Wild Flowers Month by Month," and although not so exciting or exacting as bird photography, is nevertheless quite as interesting, and, moreover, calls for an equal amount of skill and enthusiasm. And Mr. Step is an enthusiast. He revels in his descriptions of the beauties of the wild flowers he pictures so cleverly, and although the present volume only deals with the months of March, April, May, and June, he manages to fill 200 closely-printed pages with word pictures of the flora that blossoms during that period. In the chapter "April in the Lanes" he says:—"Dandelion in full beauty is the first thing to strike our attention here, one of the most beautiful flowers that grow; but alas! so common that few see its beauty. The incapacity for seeing beauty in common things is a great deprivation. If we could only get one of those purblind individuals to sit between us on this stone-heap and 'hold him with our glittering eye,' as did the Ancient Mariner with the wedding guest, we might in an hour's chat show him something of the perfect form and cunning workmanship, such as no artificer in the precious metal could excel, bestowed on this condemned plant. We would pluck one of these flower-stalks and show him how a slender column to support a massive capital may be contrived of little solid material, and yet be strong enough to bear the

strain at the top, to bend before the wind without breaking. We would show him how the beauty of the capital as a whole was not achieved by sacrificing beauty and exquisite finish in the parts whereof it is composed; and we would compel him to understand the marvel of that "clock" or "puff," and the important work it performs in a perfect manner."

The photo-botanist will find a plethora of good things between the covers of this book, the illustrations of which are as good as they are lavish. Not much in the way of practical hints for flower photography is given, but the value of photography to the botanist is acknowledged by the author at every turn. He suggests a stand camera and good lens for the work, as the possessor of a hand camera cannot hope to accomplish much in the direction of wild-flower photography. Comparatively long exposures are necessitated by the yellow, red, and green of his subjects, and by the dim light of woods. In the open, upon colonies of plants, the hand camera may be useful; but at close quarters, on the individual plant, it will rarely give good results. Orthochromatic plates are absolutely necessary, and a yellow screen of medium tint should be used. Altogether, this book can be regarded as opening up new ground for photographers, who will not fail to derive considerable instruction and pleasure from a careful perusal of its contents.

"Wild Birds at Home."

The third nature-book that we have to consider is unlike the other two, inasmuch as it is composed entirely of pictures, is much smaller in size, and costs but 6d. This last fact is, perhaps, more astonishing than the wonder that will be created on inspecting the really beautiful illustrations. These fully bear out the title of the book—"Wild Birds at Home"—and, as specimens of nature-photography and high-class printing, would be hard to beat. They are all by Charles Kirk, and some of them are very beautiful little pictures, apart from their undoubted value as nature-photographs.

ONE-PLATE COLOUR PHOTOGRAPHY.

HERR SCHINZEL describes, in the current number of the "Photographisches Wochenblatt," the following process for producing photographs in natural colours, which, he states, differs from all previous processes, in that separate component pictures are not required, but that with one plate a single exposure is made, and on this one plate the multi-coloured image is produced.

The plate is coated with a number of coloured gelatino-bromide films, which are separated by films of plain gelatine. The individual films are so coloured that a part of the incident light is absorbed in each film, and by the addition of suitable sensitisers the absorption of the coloured rays is made as perfect as possible. For example, in using three films, the top one will be coloured yellow or orange, and obviously be sensitised for the blue violet rays; the middle one will be coloured blue or blue-green, and be sensitised for reddish orange; whilst the bottom one will be coloured red and sensitised for yellowish green. If a plate thus prepared is exposed on any subject, a part of the rays will be absorbed by each film, and by development and fixing the corresponding component parts of the picture will be produced.*

The development of the polychromatic picture is founded on the catalytic property of metallic silver. If a developed and fixed plate is immersed in a 2 per cent. aqueous solution of hydrogen peroxide, this will be decomposed where there is metallic silver, and oxygen set free. If, now, such dyes have been chosen for colouring the gelatino-bromide films, that they, by oxidation, are easily converted into colourless compounds, they will be bleached out where there is metallic silver. It is easy to conceive that after the removal of the silver, coloured pictures will be obtained, which will be not complementary to, but according to, the colours of Nature.

Moreover, it is not essential that the oxidation products of the dyes should be colourless. It will be quite enough if the power of the pigments to stain the gelatine is destroyed by the oxidation, and that they become soluble in water. Hence it would be possible to use comparatively stable dyes, so that the coloured images would bleach with difficulty in sun or daylight.

The polychrome image can be printed from the plate on to a sheet of white paper, prepared in the same way, but the picture will appear less brilliant than when observed as a transparency.

As regards the practical working of the process, it should be noted that the gelatino-bromide of silver films must be "wasserecht" stained—that is to say, that the dyes must not be soluble in water—and that they must not be affected by development and fixation, or, if this the case, they must be reformed before the treatment with the peroxide. At the same time, any sensitisers that may be used which will not bleach, and whose colour does not agree with that of the films, can be removed.

The films of plain gelatine between the individual coloured films have the effect of preventing the action of the nascent oxygen developed in one film from acting on the others, and of confining the gas as far as possible to the requisite coloured film. For this last reason the top film is also coated with a transparent gelatine film.

It is advisable, before treating the gelatine with peroxide, to harden it, but not so that the diffusion of the peroxide solution is rendered too difficult. It is well known that peroxide has the property of dissolving metallic silver, and that the oxidation would be brought to a premature stop. This disadvantage is obviated by the addition of a small quantity of soda to the peroxide solution. As, however, many dyes are altered by the alkalinity of this solution, it is necessary to regenerate them by immersion in an acid solution

*The preparation of the plates here described naturally recalls the "three-colour plate" of Dr. Smith, of Zurich (see B.J.P., May 5, 1905).—Eds. B.J.P.

Briefly, the essential advantages of this process are that only one exposure is made, and the printable and more or less true-to-nature picture is produced on the negative plate. The preparation of the pictures is extremely simple, no more solutions are necessary than in the production of pictures on bromide paper—namely, developer, fixing, and instead of the toning bath the peroxide solution—for if the latter, when the oxidation process has continued long enough, is acidified, the solution of the silver is effected.

This method represents, therefore, a direct process of colour

photography suitable for instantaneous work, and one in which the printable image is produced on the original plate in body colours.

We learn that this process is patented in all civilised countries, and that further details are promised, which, we are sure, will be anxiously awaited. Nevertheless, it is well not to be over-sanguine in regard to the possibilities of such a process in practice. It seems that a composite plate such as that which Herr Schinzel proposes using is necessarily very slow, and instantaneous exposures will be possible only under the very best conditions.

PHOTOGRAPHS UPON COINS, SPOONS, AND PLATES.

That branch of the art of photography by which photographs are produced upon watch cases and dials, can be applied to many other articles for ornamental purposes. An excellent and very profitable business can be made by the production of these miniature photographs for souvenir and other purposes; a specialty might be made of this work to advantage in many places.

Souvenir Photography.

The cost of material is very small; still determination and carefulness in practice are the essential points to be attended to. The line of souvenir photography is almost unlimited, pictures upon the exteriors of glass bottomed tankards, upon the sides of china cups, china plates, the interiors of the bowls of spoons, and upon one side of silver coins, form only a few of the items that come under heading of souvenir work. Orders are sometimes given for as many as one hundred special prints upon silver quarters to be used as presents to guests and friends in connection with a silver wedding, the date upon the reverse side of the coin indicating the twenty-fifth year of married life, the souvenir being as pretty as it is novel. Just how this class of work is to be carried out successfully and in a thoroughly practical manner is described in an article by A. J. Jarman in the current number of "Wilson's."

Camera Accessories.

The author says:—In the first place, pictures of this kind are to be made by the carbon process, by the single transfer process. Of course in this case the negative must be made in reverse. To attempt this work by double transfer is almost impracticable, but by single transfer every operation is simplified and brought down to a simple and effective operation. It will be necessary to secure a small stock of material for general work, which must be kept on hand. If it is intended to carry on this class of business as a specialty, it will be necessary to procure a prism with attachment to the hood of the camera, this is to enable a reverse negative to be taken of the objects desired. A lens of the rectilinear type of about ten to fifteen inches focus is the best suited. The camera need not be larger than is necessary to take a $6\frac{1}{2} \times 8\frac{1}{2}$ plate, but it must possess considerable length of bellows, capable of extending to about three feet, and closing up to the smallest possible space.

When the prism is used the camera is placed at right angle to the object to be copied. The operator will soon become accustomed to the method of working. The plate holder or dark slide should be suitable for working the wet plate process, because such a holder enables either wet plates or dry plates to be used; in every case the shadows in the negative must be clean and clear, otherwise the print when developed upon the metal base will look too dull.

Chemicals to Order.

Materials required:—One pound of Heinrich's soft gelatine; salicylic acid, one ounce; strong ammonia, one pound; bichromate of potash, one pound; chrome alum, one pound; common alum (crystallized), one pound; carbonate of ammonia, half-pound; white granulated sugar, one pound; half a dozen wide-mouth bottles; one

pound of alkaline or crystalline lacquer; half a pound of thinner, one small frying oven, one small gas stove, a one-pound can of potash lye, half a dozen trays for developing and fixing—enamelled iron will do—in sizes from 4×5 to 10×12 , half a pound of glycerine, one six-inch squeegee, one yard of thin indiarubber cloth, one or two dozen pieces of carbon tissue 8×10 , two or three small glass funnels (6 to 16 ozs.), three glass graduates (2 oz., 4 oz., 16 oz.), one oatmeal kettle two pints (the capacity applies to the inner vessel).

Sensitising Formulæ.

This list, although long, is not expensive, five or six dollars will cover everything. Should it be desired to purchase the carbon tissue by the roll, the following colours will be found most suitable for the greatest bulk of the work: standard brown, engraving black, and portrait brown. The following solutions for sensitising will be found to work well.

No. 1.

Bichromate of potash (cp.).....	1 ounce.
Filtered water	25 ounces.
Strong ammonia	10 drops.

As soon as the crystals of bichromate are dissolved, filter into a clean, wide-mouth amber bottle.

No. 2.

Bichromate of potash (cp.).....	1 ounce.
Carbonate of ammonia	20 grains.
Filtered water	25 ounces.

As soon as the crystals are completely dissolved the following must be added:—

Salicylic acid	20 grains.
Hot water	2 ounces.
Glycerine	15 drops.

The solutions must be well mixed by the use of a strip of clean glass, and filtered as in the case of No. 1.

Working from Ordinary Photographs.

Carbon tissue sensitised in this solution will keep longer than if sensitised in No. 1. In every other respect they act the same. To produce the carbon print upon coins proceed as follows:—Having obtained the photographs to be copied, which should be of equal size, and printed upon the same kind of paper or the result will not be satisfactory, cut each print to suitable sized ellipse, draw a circle upon a sheet of white cardboard, and arrange the two prints within the circle, the tops inclining towards each other. A wreath of leaves with the flower forget-me-not, may be entwined around the inner part of the circle, with a floral addition to the spaces between portraits if desired. The portraits should face each other. The painting of this ornamentation may be done with india ink. The arrangement being now completed, several negatives are made, the circle upon the cardboard being a guide so as to enable the reduction to be made within the diameter of the coin. Assuming that there are one hundred silver quarters to be treated, then ten negatives should be made. If a gelatine dry plate is used it is a good plan

to take a 5 x 7 plate (a slow plate is best suited). Make a diamond cut down the centre of the length and two cuts across the plate in the dark-room so as to give six small plates. Having arranged the focus, test a plate for time of exposure, and bear this in mind—these miniature negatives must always be snappy, slightly hard, with clear shadows. Such negatives produce the effect desired for a metallic base. The negatives being made, the coins must be prepared. That side of the coin where the picture is to be transferred must be ground off to secure a flat surface. This is done by any worker in silver, and polished so as to give a clean surface. As soon as the coins have been all ground and polished, they must be cleaned by placing them in a solution of potash lye to remove all grease and dirt, taking care not to scratch the surface. This is best accomplished by placing upon the thumb and fingers of the left hand a set of indiarubber finger tips, then by pressing into a piece of vulcanised indiarubber tube a tuft of absorbent cotton so as to use this as a mop. The coins are taken one at a time, laid upon a piece of celluloid, and wiped with the mop so as to remove any greasy matter. The coin must now be rinsed in running water and placed upon its edge upon a strip of thick white blotting-board to dry. When they have all been cleaned they must be matted upon the polished surface, by soaking in a dilute solution of nitric acid (1 in 20) for a few minutes and then scouring with a fine brass wire scratch-brush, or a satin surface may be produced by having them all treated by an electro-plater who understands this class of work. Be sure to direct that each coin must be wrapped in soft tissue paper, separately; this is to ensure their not becoming scratched.

The next operation will be to prepare the gelatine substratum, and to sensitise the carbon tissue; either engraving black or portrait brown will be best suited for transfer to silver coins.

Sensitising the Tissue.

Pour into a clean tray the bichromate solution, take a piece of the tissue, say 8 x 10, dust the surface then with the thumb and forefinger of each hand take the tissue by the top corners, dip it completely beneath the solution, see that no air bubbles rest upon the surface—if there are any remove them with a soft camel's-hair brush, by stroking the surface over first lengthwise then crosswise. Allow the tissue to soak face up for one minute and a half, then turn it face down to soak for the same time. Then remove it and place it face down upon a clean sheet of glass 11 x 14. Place a piece of the thin indiarubber cloth upon the back of the tissue, then holding one end down apply the squeegee with moderate pressure, stroking several times from the spot that is held. Remove the cloth and wipe the excess of bichromate solution from the back of the tissue with a piece of clean rag. Lift each top corner of the tissue, insert a wooden clip. Lift the tissue off the glass plate carefully, and hang it to dry in a room free from dust. Drying will be complete in about four hours. Of course these operations must be conducted away from active light. Prepare a number of pieces of tissue in the same way, and when dry place them in a printing frame in which a piece of stout glass has been placed covered with a sheet of black paper; the tissue will keep well for several days by this means, away from light and air. The substratum must now be made up as follows:—

Heinrich's soft gelatine	1 ounce.
Filtered water	20 ounces.
White sugar	$\frac{1}{2}$ ounce.

Place this material in the inner vessel of a double kettle. When well soaked place some water in the outer vessel, then place upon a gas stove until the water in the outer vessel boils. Stir the gelatine until it is completely dissolved. Add five grains of chrome alum dissolved in one ounce of hot water, stir this in with the gelatine, then add gradually one ounce of rectified alcohol a few drops at a time. The boiling must not be continued after the gelatine

has become dissolved. A common tumbler may now be used to filter the gelatine solution into, by washing out a piece of cheese cloth and holding it over the top of the tumbler folded into two thicknesses, and allowed to hang down slightly in bag form. Pour some of the gelatine solution through the cloth filling the tumbler about two-thirds full. Now take each coin, wash it in running water until all greasiness disappears, using a piece of absorbent cotton if necessary. Drain the water off, then apply a small quantity of the gelatine solution. Drain the coin, and stand it upon blotting paper to dry as in the first instance, shifting the coins once so that they do not stick to the paper at the edge. As soon as dry they are ready to receive the image. The reduced negative must now be adjusted upon a piece of 4 x 5 clean glass, held in place by a strip of gummed paper, with a circle cut out of a piece of black paper placed upon the film side of the negative, so as to admit of a disc of the sensitised tissue being placed therein of the size of the coin or just a little less in diameter. The cut-out must be marked at the top with a T, the disc of tissue being marked also; this will indicate the top of the picture when the printed tissue is placed upon the coin. All the negatives required for the work must be fitted up in the same manner, each upon a 4 x 5 glass.

Printing and Development.

In printing these miniatures, assuming that all the negatives are uniform in density, all that will be required will be to employ another negative of about the same density as a test, by placing a small strip of ordinary printing-out paper upon it, and exposing it at the same time, so that when the silver print is about one-third printed the carbons will have reached the right depth also. The printing frames must now be taken into a room lighted by yellow light. There should be a sink in this room to enable the operations of developing, etc., to be carried on. The gelatine solution must now be warmed in the double kettle, and a small quantity filtered into a tumbler, and allowed to become nearly cold. Stand this near at hand ready for use. Remove the pieces of carbon tissue from the printing frames, lay them face down in a shallow cardboard box, take two or three of them and place in a tray of clean cold water. Meantime, place the required number of prepared coins into another small tray of water. When they are well wetted, remove one of them; dip the coin into the gelatine solution; remove one of the printed carbon tissue discs; place it upon the gelatinised surface (be sure it is in the right position); place a small piece of this indiarubber cloth upon the back of the tissue and carefully rub it down with a stiff indiarubber ink eraser, which answers the purpose as well as a squeegee. Treat all the exposed discs in the same manner. Allow them to stand fifteen minutes. Now place them in a dish of warm water (an enamelled iron pan answers the purpose). Be sure the water is not hot, because this would blister the print. In the course of a minute or two the colouring matter of the tissue will be seen to ooze from the edges of the coin. Place both hands in the water, holding the coin between the thumb and finger of one hand, then remove the paper support of the tissue with the thumb and finger of the other hand. Swish the coin to and fro beneath the water. The image will soon make its appearance. Treat all the coins in the same manner. Sometimes the paper support of the tissue comes off the coins without assistance and floats upon the water. Pick these out of the tray, then proceed to wash all the coins beneath the warm water.

Photographs on Spoons and Bowls.

Sometimes very handsomely decorated silver spoons are used as souvenirs, the bowl being gilt and satin printed. A photograph is placed upon the interior of the bowl. The operation is identical with the transfer of a carbon print upon a coin, only in this case a template must be cut out of a piece of thin cardboard to the exact size required for the bowl, also to be used as a gauge to cut the

use by. Each piece of tissue is cut to a true oval (not an ellipse). The photograph used in this case is usually a small head and bust of a lady or gentleman, carefully vignetted; this is accomplished by placing the miniature negative upon a 4 x 5 piece of clean glass, lining it with a few strips of gummed paper, then a true oval is cut out of a piece of black or orange-coloured paper, and fixed with gum upon the surface of the negative; the vignetting is done by rubbing in upon the front of the glass plate with a stubby brush. As soon as the negative thus prepared is thoroughly dry it is ready for the printing operation, which is identical with that for the coins, the head of the figure being usually placed at the largest end of the oval, so no mistake is likely to occur as to position when placing the print upon the inner surface of the bowl. Assuming that half a dozen spoons are to be treated, the prints must be made in the same way as described, but the material to be used to cause the print to adhere to the bowl differs from that used for the coin. The syrup is made of:—

White granulated sugar	4 ounces.
Hot water	8 ounces.

Allow this syrup to become cold, when it is ready for use. The spoons are cleaned by dipping them into a warm solution of potash; rub them very lightly with a tuft of absorbent cotton; wash them in a stream of water; dip the bowl into the syrup. Now, having one of the oval exposed pieces of carbon tissue ready, allow it to soak in clean water until it lies flat; then place it in the spoon bowl with its face to the metal; now press it into position by the thumb or the tip of the forefinger; then place the bowl down upon a piece of chamois leather, holding the handle with one hand; stroke the tissue from the centre to the outside with either the thumb or forefinger, in the same way as using a squeegee. Allow the spoons treated to stand for a quarter of an hour, then immerse them in a tray of warm water. In a short time the paper support of the tissue will release itself and float off. All that is necessary to complete the development is to lave the spoon backward and forward in the warm water, by holding the handle. The print will soon be developed. It is then carefully washed in running water, treated in the alum bath, washed, and dried. When dry it must be coated with the transparent varnish, just the same as coin photographs, and dried.

The effect of these beautiful little pictures will be astonishing, and as souvenirs will prove a very attractive object. Never use chrome alum in the alum bath, because this makes the gelatine film far too hard; in fact, this is the true cause of cracking and peeling of the picture. A certain amount of pliability is necessary for any carbon print that is transferred to metal, so that if the film is hardened too much this pliability is lost and the picture suffers in consequence.

Fixing, Washing, and Drying.

If the exposure has been right, the images will develop quickly and stand out beautifully upon the silver base. Each coin must now be washed in a soft stream of running water from the tap, then placed in an alum bath composed of:—

Powdered white alum	1 ounce.
Water	50 ounces.

Filter this solution, and as each print is developed and washed place it in the alum bath. Treat them all in the same manner, allowing them to remain in the alum solution three minutes. Now remove and place them in a tray of clean water. Allow a gentle stream of water to flow over them for five minutes, then remove and place them upon a strip of blotting paper to absorb the excess of water. Now change them to another strip of blotting paper to dry. Changing them in the above manner is necessary to prevent the fibre from the blotting paper creeping upon the surface. As soon as the prints are quite dry they must be coated with a thinned lacquer known as alkaline or crystalline, sometimes called banana oil varnish. All these various names are given to what is really celluloid varnish. When each print has been coated the excess of varnish must be absorbed by using a small piece of torn blotting paper, by touching the liquid that drains when holding the coin vertically. As soon as this varnishing is completed place the coin on edge upon a clean strip of wood in a tin oven, which can be easily made out of a biscuit tin; heating the tin by means of a small gas stove with only a very small jet beneath. The oven is best placed a few inches above the stove, or the prints may be allowed to dry spontaneously. Upon examination it will be found that these miniature carbon prints are perfect in every detail, and well protected against damp, showing up as they do in a very beautiful manner, forming a novel and handsome souvenir.

A LETTER TO A MIDDLE-CLASS PROFESSIONAL.

MR. J.—I have just been looking over some of your latest work, and I am writing you with regard to it.

It may have struck you that, whereas you are pretty successful with the sitter, there is a general appearance of—shall we say?—incompleteness connected with it. Now this is the case with many good men, and the reasons for it are practically always the same. Of course, it may be caused by your type of client, but in this case it is not what I mean and do not intend to discuss, though, of course, we all know that the common, or middle-class sitter is much more difficult to handle than the upper ten.

Perhaps you have at times wondered to yourself—"What makes the difference between my work and so and so's? My lighting, posing, and retouching is as good, yet my stuff has an indefinable appearance of inferiority."

In some cases the mere finishing (mounting, etc.) will account for the difference; but acknowledging, for the sake of argument, that this is equal to the other fellow's, then, believe me, it is the background. The background, though requiring little thought from many professionals, has at least as much to do with the general result—i.e., not likeness—

as lighting, or even pose. Mind you, I mean looking at the photograph as one who does not know the sitter.

A recent portrait of yours constrains me to make these remarks—in fact, it may be taken as the cause of this letter. The portrait itself is good, when you have found it, but the background, which simply jumps at you, is awful, and seems to consist mainly of blobs of white and serpentine line. On looking into it, I see it is an abortion, intended to represent a pillar and curtain, distant landscape, flowers and flower-pot, like nothing seen on earth or over it. In fact, it is one of the things that even yet, in spite of the late H. P. Robinson's teaching, still finds a place in the half-tone catalogues of all dealers.

You are evidently making the usual mistake of thinking that the background does not matter much. They are so cheap, so easy to place in position, and of so little trouble compared with getting pose and expression, that you think that, as they are of such minor importance, they may as well be pretty in themselves. No greater mistake could be made; the background has everything to do with it, though in a negative way—it must be seen, but not noticed. The whole use of the ground is to throw up the head so that it

becomes the chief feature of interest. With a poor ground, the eye keeps wandering from the head to the ground, and there is no sense of rest and no focus of interest.

Moreover, a good background is no dearer in cost than a poor one; only selection and a knowledge of the necessity of subordination are needed. Once obtained, a good ground is a great economy, for putting aside the fact that no one thing so easily gives a common appearance to a photograph as a bad background, a good ground is much more useful. You can use it for almost anything, and, being unobtrusive, the frequency with which it is used will not be noticed, for the figure will so occupy attention that no thought is given to the ground. This is as it should be. The figure is seen at once and noted, whilst the background is quite secondary.

On the other hand, with a cheap ground that is all light spots and masses that irritate and distract the eye, if it be used at all frequently, it must be noticed, for the background throws itself at you, and is often more pronounced than the figure it is supposed to set off.

You will be thinking that I am writing an immense amount of cackle, but have not yet given you any practical advice. Well, the whole of my advice is "unobtrusiveness." Get that in your ground and you are right.

Perhaps the best grounds for general use are the plain-graded ones, and these have the undoubted advantage, as the English background painter can paint them without any great blunder, and you are almost sure to get them good. The simplest grounds of this description are graded from a dark tint gradually to a lighter one, and may be graded from light side of studio to dark, or from top to bottom, having either light or dark side of ground in position required. The more usual is across. With light side of ground nearest skylight you get breadth, with dark side to skylight you get more relief. If you have them graded top to bottom, it is better to have the darker side at bottom, thus hiding the lower and less important parts of body. Be careful, however, that light part of ground is not of same tone as the face of your sitter.

These grounds can be used for anything—heads, three-quarters, full lengths, or groups. With them, though the effect is practically that of a plain ground, you avoid the inlaid appearance liable to occur with these latter.

The cloud ground is as useful as above, but slightly more difficult to obtain good, the clouds frequently being too pronounced. With these it is only necessary to get correct part of ground to throw up the face. Usually a little light is placed behind shadow of side of head.

Plain grounds, either dark or very light, scarcely ever middle tone, are used extensively by the best houses, chiefly on account of their simplicity and utter lack of anything to distract the attention. They are an index of the reaction that has set in against what are known as scenic grounds, against which I am chiefly warning you, and of which more anon.

I refrain from advising these plain grounds to you, for they may not suit your clientèle; and, as I said before, they are liable to make the figure appear inlaid. I was particularly struck at last year's Royal Academy exhibition by the absolute failure of the painters to cope with this problem, and if they cannot do it with the aid of colour, the mediocre camera-man must climb down. Properly used, however, no other grounds are so thoroughly successful or so distinctive. Dark-green and black are the more useful colours for the dark grounds, whilst perfectly white and very light-grey grounds are the best light tints.

These grounds have the advantage of being capable of home manufacture. Extra wide (6 ft.) art serge makes a good head or three-quarter length ground. For ladies and children in light

dress, a length of 8-ft. wide sheeting makes a good ground. The disadvantage is need of careful exposure and development. The ground must come out dead-white, whilst the dress (if white) is the fraction of a tone darker at its highest light, and the light side of face yet another fraction darker in tone than the ground. When selecting a light-grey ground, however, it is usually chosen so that a white dress is lighter in tone, with the face-tone slightly darker than the ground. Of course, these grounds are of no use for men, nor children or women in dark frocks; for though a white dress looks well against a dark ground, the contrary—a dark dress and light ground—does not hold good, for the light tones of the chief point of interest—"the face"—are not contrasted with the ground sufficiently to compete with the strong contrast between dress and ground.

I have left scenic grounds to the last, for though the most used by the incapable, they are in reality the least useful and least artistic of any, and, moreover, are difficult to obtain good.

It is against cheap scenic grounds that my preliminary tirade was directed. Unfortunately it is apparently impossible to get a good English background of this description, the only ones having any claim for excellence coming from one or two houses in America.

The chief fault of these grounds is superabundance of detail, introducing complexity of interest. The worst grounds add bad drawing and impossible perspective, together with painted representation of accessories. Accessories of any sort are bad enough, but the painted ones, such as windows, looking-glasses, fireplaces, etc., are a thousandfold more abominable than the usual, but solid, shams.

The great necessity is to have a ground with broad effects, little detail, and good perspective, and atmosphere to give distance.

A good ground with these attributes is then extremely useful, for the public frequently ask for this type of ground, but whenever possible my advice is to use a graded or plain ground, and stick to it. If you must have a scenic ground, see the ground itself before purchasing, and get a good one. Probably you will find this latter advice easier in the case of exterior rather than interior effects, for difficult as it is to get good exteriors, interiors are even worse, for you must remember that the sitter should be taken amidst usual surroundings. Since this is usually against a wall paper of flowered design—an utter impossibility as a ground—we can fall back on our plain and graded ground, but the "artist" insists on giving us the ancient pillar-and-curtain conservatory and such-like obsolete abominations. The only decent or even possible interior I have yet seen was painted to represent a panelled wall, and, in the absence of a better, the suggestion may be valuable.—Yours,

STUDIOSUS.

PROCESS Blocks for Photographers.—In reference to the note on another page reminding professionals of the business in half-tone blocks from their photographs, the work of one firm making a specialty of this kind of business has recently come before our notice—viz., that of Messrs. E. Hamel and Co., Nottingham—who do a varied business in screen and line blocks, and are a firm who may be entrusted with work demanding special care.

ADMIRERS of Miss Constance Ellis's pictorial work, and we include ourselves among the keenest of this number, will be glad to peruse an article in the August "Girls' Realm," in which Miss Ellis chats of her photography, and shows some of her successful figure studies in the making.

We learn that the Hartlepool Photographic and Sketching Society and the West Hartlepool Amateur Photographic Society have now become one body under the title of the former

A DEVELOPER FOR STUDIO NEGATIVES.

the current number of "Photographic Scraps" C. Harold Smith discusses the good qualities of the Ilford Zenith plate for studio portraiture. He says:—"As regards development, for studio work the Ilford pyro-soda is the standard developer. There are, however, occasions when the exposure is known to have been very short, and a pyro-metol developer may be preferred. With pyro-metol the clearance of the image is much quicker, and in practical result there is more shadow-detail for the same density of high lights. The plate develops quickly with it, and does not need to be and should not be overdeveloped. This developer does not, however, afford the immense latitude of the pyro-soda, and it should never be used where overexposure has been possible. A most convenient method to the man who uses the Ilford pyro-soda as a general rule, is to keep a solution of metol separately to add to it; or rather, to make up the developer with metol taking the place of a part of the pyro. The following is the metol solution:—

Water	20 ozs.
Metol	50 grains.
Sodium sulphite	1 oz.

(Dissolve in the order named.)

should be used thus:—

Ilford No. 1 pyro solution	1 part
Metol solution	1 part.
Ilford No. 2 soda solution	2 parts.

The No. 1 pyro solution for studio work should always be made up with 1 oz. of stock solution to the pint, and the bromide be omitted in the No. 2 soda solution, whether for use as pyro-soda, or pyro-metol-soda.

Regularity, and therefore quality, of result can only be obtained by using fresh developer for each plate, whatever the developer. A developer used a second time has taken into itself some bromide from the first plate; the image takes some two or three times longer to develop, and in proportion to this is fully developed much sooner. The 'multiplying factor' is lower. There is also less detail in the shadows, very noticeable in portraiture."

OPENING OF THE ROTARY PHOTOGRAPHIC COMPANY'S SOCIAL CLUB.

On Saturday last a party of guests and friends of the Rotary Photographic Company journeyed to West Drayton, where the works of the company are situated, to be present at the inauguration of a social club and grounds for the use of the employees.

A large house by the side of a delightful little river flowing into the Thames has been fitted up for the purposes of a social club for the employees living at Yiewsley. Billiard and music rooms have been provided and furnished by the directors, and, for the benefit of the employees in the London office of the company, several completely furnished rooms have been provided for their free use at week-ends. In addition to the orchard and grounds surrounding the club, a capital sports field has been provided, in which on Saturday races were held, and swimming matches took place in the river, followed by a concert dance.

The premises include a dining room to seat fifty, general and reading rooms, and baths, with special accommodation for the girls and young men employed.

The formal opening was performed by Mrs. Haenel, wife of the managing director. A golden key had been subscribed for this purpose by the employees, and will doubtless be kept as a valued souvenir of an interesting event in the annals of the company.

Should the condition of business allow of it, a start will be made next year in the provision of cottages for the workers. The directors are also forming a lending library in connection with the club, and

the lot of the Rotary Company's employees at the works should be a very happy one.

After tea had been served on the lawn of the newly opened club, the guests were conducted over the works and shown evidences of the immense output of the firm in the way of picture postcards.

FORTHCOMING EXHIBITIONS.

July 4 to August 12.—Northern Photographic Exhibition. Secretary, F. G. Issott, 62, Compton Road, Harehills, Leeds.

August 7.—Andover. Hon. Secretary, W. I. Gradidge, Jubilee House, Andover.

August 24 to September 21.—Berwick-upon-Tweed Arts Club. Hon. Secretary Pictorial Photography Section, H. Hancocks, 38, Ravensdowne, Berwick-upon-Tweed.

September 8.—International Exhibition at Budapest. Address, Secretary of the Photo-Club, Egyetem-ter 5, Budapest, IV.

September 15-October 21.—Photographic Salon, 5a, Pall Mall East. Hon. Secretary, Reginald Craigie, Camera Club, Charing Cross Road, K.C.

September 21-October 28.—Royal Photographic Society, New Gallery, 121, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

October 17-18-19.—Isle of Wight Photographic Society. Hon. Sec., V. Howard Burgess, 53, Pyle Street, Newport, I. of W.

October 18-21.—Rotherham Photographic Society. Hon. Secretary, H. C. Hemmingway, Tooker Road, Rotherham.

October 19-21.—Grangemouth Amateur Photographic Association. Hon. Secretary, Robert Marshall, 3, Park Terrace, Grangemouth.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

November.—Edinburgh University C.C. Hon. Secretary, Harold C. Simpson, University Union, Edinburgh.

November.—Bristol and Clifton Arts and Crafts Society. Secretary, R. H. Parr, 5, Grove Buildings, Blackboy Hill, Bristol.

November, December, January.—Second American Photographic Salon. H. Snowden Ward, 6, Farringdon Avenue, London, E.C.; Wm. T. Knox, 279, Washington Street, New York City, U.S.A.

November 3, 4, 5.—Metherwell Young Men's Institute C.C. Hon. Secretaries, James Dunlop, Myrtlebank, Metherwell, and Archibald Matthews, 24, Enfield Place, Ladywell, Metherwell.

November 8-15.—Croydon Camera Club. Hon. Sec., W. H. Rogers, 88, Woodville Road, Thornton Heath.

November 14, 15, 16.—Ipswich Camera Club. Hon. Sec., R. H. Sutton, 37, Henley Road, Ipswich.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

November 25-December 2.—Glasgow Eastern Amateur Photographic Association.

November 25-December 2.—Glasgow Eastern A.Ph.A. Hon. Secretaries, Thomas B. Kirkhope, 37, Winston Street, Parkhead, Glasgow, and John Brough, 68, Dalmarnock Street, Parkhead, Glasgow.

December.—Muirkirk A.Ph.A. Hon. Secretary, William Barrowman, Ayr View, Muirkirk.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sargent, 55, The Drive, Hove.

December 6-7.—Watford Camera Club. Hon. Secretary, E. H. Jackson, 100, High Street, Watford.

December 12.—The Scottish Photographic Federation Lantern Slide Competition. Entries to Hon. Secretary, John B. MacLachlan, Blairgowrie.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

December-January.—Wishaw Ph. A. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January, 1906.—Shettleston Camera Club. Hon. Secretary, Wm. Kitson, Hawthorne Villa, Shettleston.

January 13-February 3, 1906.—The Third Scottish National Salon at Dundee. Hon. Secretary, V. C. Baird, Broughty Ferry. Entries close December 30, 1905.

February 13-27, 1906.—Greenock C.C. Hon. Secretary, W. D. Boyd, 2, Church Place, Greenock.

March, 1906.—Larkhall C.C. Hon. Secretary, Robert Rodger, 26, McNeill Street, Larkhall.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern P.A. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 19-24, 1906. Sunderland Photographic Association. Hon. Sec., William E. Kieffer, Stirling Street, Sunderland.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 1, 1906.—Coatbridge Co.-Op. C.C. Hon. Secretary, James Robb, 6, Windsor Terrace, Blenheim, Coatbridge.

FORTHCOMING COMPETITIONS.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 in prizes for photographs taken with Thornton-Pickard cameras or shutters.

October 31.—"Zigo." Cash prizes for prints on "Zigo" self-toning paper. Thos. Illingworth and Co., Limited, Willesden Junction, London, N.W.

November 30.—Royal Photographic Society "Affiliation" Print Competition. Particulars from the Secretary, 66, Russell Square, W.C.

December 30.—Royal Photographic Society "Affiliation" Lecture Competition: (a) Illustrated lecture descriptive of a tour; (b) Illustrated technical lecture. Particulars from the Secretary R.P.S., 66, Russell Square, London, W.C.

For selling a celluloid comb instead of a bone one, a firm of drapers in Kilburn had to pay £50 damages to a lady of West Hampstead on Monday last. The lady stated that she bought the comb on the understanding that it was bone. Some days afterwards, as she was drying a pet dog in front of the fire, the comb in her hair suddenly burst into flame, with the result that a quantity of her hair was burned off, and that she became partially bald. To a sympathetic jury, Miss Carter showed a great mass of the hair which had been burned from her head, with the remains of the comb in it. At the earnest request of her counsel she also reluctantly removed her hat, and showed the jury "the place that had not healed." She said she bought a set of combs on exchange. For the defence, one shop assistant said that she knew the difference between bone and celluloid, and could not possibly have made a mistake. Another said that she detected the difference by rubbing the combs on her skirt, and if there was a smell of camphor she knew they were celluloid. An analytical chemist explained that celluloid was a mixture of highly inflammable materials. In some shops, he said, it was the custom to mark celluloid goods by stamping them. Judge Selfe expressed the opinion that it was stretching the point rather too much to hold the draper responsible for damages in such a case; but the jury took a different view.

MR. O. MOLLER is now the Hon. Secretary of the Sunderland Camera Club. His address is 1, Thornhill Gardens, Sunderland. The Blaydon and District Camera Club has also got a new Secretary in Mr. J. Parker, of 7, Evelyn Terrace, Blaydon-on-Tyne.

Photo-Mechanical Notes.

Artistry in Process Engraving.

THE exhibition of photo-mechanical reproduction processes which has just reopened at Manchester did not aspire to be judged as the product of a distinct art—or, at least, those most intimately associated with photo-mechanical work would not wish to set the chemical engraving by the side of the work of the old engravers. For the whole tendency of process engraving has been towards abolishing character of any kind. Commercially, a reproduction process which is automatic from first to last is perfect, and although there is no such process, and probably never will be, the aim of the process-engraver has been to make his business a factory of blocks and plates, in which the work can be turned out with the least intelligence on the part of the workmen. In a commercial sense, considering present conditions, that course is almost the only possible one, but its effect on process as a craft, let alone an art, is inevitably disastrous. Hence it is not surprising to find an art critic writing of process:—

"I have never longed to possess a good, bad, or indifferent print of any process block. I have never felt that I could cherish an impression of a process engraving as a thing intrinsically valuable; none of the exhibits at South Kensington made me feel it and I have an obstinate, deep-rooted conviction that I never shall feel it."

Analysing this repugnance, he finds it to come from the lack of character. Mezzotint, etching, wood engraving, and lithography each modified the original, so that it is something more than a simple reproduction. The impressions have a kind of personality of their own. But process engraving—it is heavy, lifeless, and tedious. We are glad to find that some of the photogravures at South Kensington could be excepted from this denunciation:—

"Messrs. Walker and Cockerell's and Messrs. Allen and Co.'s photogravures of pictures by Turner, Romney, and Gainsborough (Nos. 114, 115, 116, 117, 101, and 102) are as much reinterpretations of the originals as the work of a line-engraver or mezzotinter would be. The employment of photography makes them more accurate with regard to line and spacing, but the defects of photography make the translation of tones less accurate and less intelligent than an engraver relying only on his visual faculties would have made them. The surface quality of the prints is far from unpleasant, though there is a general tendency to make them too heavy and too dark. Messrs. T. and R. Annan have wisely recognised the limitations of the process, and have turned their attentions to the production of a sympathetic and agreeable surface of print. Their photogravures of paintings by Sir James Guthrie (110), Mr. J. S. Sargent (111), and Sir Henry Raeburn (112) have a rich velvety quality which is very pleasant to the eye. It is true that this charm of tone is got at the expense of accuracy of reproduction (this is especially the case with Mr. Sargent's pictures), but Messrs. Annan have here shown sound judgment, for charm is more important than accuracy in a work of art."

Considering what few process houses there are which have artistic aims before them, and considering also how utterly commercial, often debased, are the applications of the great bulk of the photo-engraver's work, it must be a long day before one or other of the photo-mechanical methods becomes a craft in the best sense of that term.

But there is another side to the question which the critic appears to overlook, and that is the rôle which process plays as a reproducer in facsimile of the artist's work. The "characters" of etchings and wood-engravings represent qualities of tones and textures which are altogether admirable. But the work of a great artist interpreted by one or other of these processes becomes something else. An old master engraved on wood by Timothy

is still a beautiful work of art, but it is virtually a new work. We do not see why a process reproduction should not enjoy the less a gratification to the artistic mind because it reproduces literally the artist's work. Mr. Pennell, whom no one accuses of partiality to photographic processes, has not dissipated his appreciation of that power in the process block which is the artist, the whole artist, and nothing but the artist—quality which should surely add, and not detract, from the value of a reproduction.

Sir William Abney on British "Process."

The recent exhibition at South Kensington was opened on Tuesday last week in the large hall of the Manchester Municipal School of Technology, when Sir William Abney delivered a short address. In his examples on the walls, he said, showed the degree of perfection to which the various processes of photography and engraving had been brought, and there were some exhibits of very great interest. Until quite recently people used to send to Germany if they wanted anything done well in this particular department. They said they could get it done better there than in this country. They disputed that idea, and attributed its existence to prejudice. To put the matter to the test, he got the Society of Arts to offer a prize for the best reproduction of the picture named "The King of the Wedding Garment." The result justified his opinion, the photographs of England excelled those of Germany. Sir William Abney gave a technical description of the processes used in the production of the various exhibits, and particularly of the way in which the colours were shown in the pictures. He had, he said, the advantage of seeing the exhibition in London, and believed it would be valuable to persons engaged in colour printing and to those who were simply amateurs in the work. The visitor would have an opportunity of inspecting some of the best work done on the Continent, in England and America. Sir William Abney, in acknowledging a number of thanks, advised his hearers to give up their ordinary cameras and go in for the three-colour cameras.

The exhibition was criticised in our pages when it opened at South Kensington (THE BRITISH JOURNAL OF PHOTOGRAPHY, Nos. 17 and 24), but we may remind visitors to it in Manchester to overlook the exhibit of the Photography and Printing Crafts Department of the School of Technology, of which the head is Mr. Charles W. Gamble. This department includes work in pure photography, photo-engraving, and various photo-mechanical methods, photographic technology, and letterpress printing. The stages in the photo-mechanical methods of relief, surface, and intaglio are shown by the objects in the cases.

Super-sensitive Bitumen.

A query of a correspondent last week has brought us several letters pointing out the advantage from a photo-engraving point of view of a more sensitive bitumen preparation, and the following notes are therefore penned with the hope of their proving of use to those engaged on the problem of a sensitive bitumen.

The following is the substance of the paper referred to by "A." by M. Colens, and appears in the "Bulletin" of the Belgian Photographic Association, 1891, p. 622.

Chromate and bitumen are combined into one mixture by means of a very easy ink, which combination is further mentioned as "bichromate bitumen." A polished zinc plate is coated with this mixture, and, after being exposed to light, is placed in a solution of collodion, left to dry (of course, in the dark), and exposed under negative for three, four, or five minutes, according to the light. The zinc plate is then heated, a film of greasy ink applied to it, and it is then washed in clean water for one or two minutes with the aid of a brush or tuft of wool. It is then dusted with the finest talc powder, and the excess dusted off; the bitumen is fixed by the action of the ink and the bichromate, and the plate left to cool. It

is then ready for etching, which is done in three stages, with inking up between each.

The above is the only reference we can find to a bichromated bitumen formula, except the following, published about 1895, in the "Photographische Chronik." Here the bitumen is an addition to a gum solution, but we must express ourselves dubious of the practical value of the formula:—

White gum arabic	60 gms.
Water	300 ccs.
Chromic acid7 gm.
Potass. bichromate (saturated solution)	30 ccs.

Extremely finely powdered bitumen is added until the solution is of fair consistency, but still flows easily. The plate is coated, whirled, and dried at a gentle heat, and exposed and developed in a broth of white sawdust, in which it is kept in agitation, being afterwards dried and burnt in. Etching is done with 1:3 iron perchloride solution.

Those who are experimenting with bitumen should also study the methods employed for preparing a bitumen which *per se* is of greater sensitiveness than the crude natural product. The following are the chief of these:—

- (1) Solution in chloroform and precipitation with three to five times the volume of ether.
- (2) Washing the raw powdered asphalt with ether, and using the dry residue as basis of the sensitive coating.
- (3) Solution of the powdered raw bitumen in as little turpentine as possible, and precipitation with several times its volume of ether.

Herr E. Valenta, however, some years ago, worked out a method of producing a highly sensitive bitumen based on the introduction of a further proportion of sulphur. The working details, as given by him, are:—100 gms. of Syrian asphalt (bitumen) are dissolved in 100 gms. of pseudocumol, in which 12 gms. of flowers of sulphur has just been dissolved, and the whole digested under an inverted condenser. The deep brown solution evolves hydrogen sulphide gas, but after about three or four hours the evolution of the latter ceases, and the cumol is distilled off. The residue, prepared as a 1:25 solution in benzole, is employed to coat the plates.

A MONSTER camera for process work has just been completed by the Camera Construction Company, Limited, of Hackney. It takes plates from whole plate to 40 in. by 40 in., and thus claims to be the largest practicable process camera yet made. A number of improvements are embodied in its construction, in particular the gearing of the focussing screens, which are both central, although the actuating handles cannot foul each other. The large dark slide is made without springs on the door of the slide, thus obviating distortion of the plate.

AN instance of very smart photography (says the "Aldershot Gazette") was forthcoming at the Bisley meeting last week, when his Majesty the King paid a visit to the camp. Mr. West, photographer, of Aldershot, had a tent on the ground, and succeeded in taking a first-class picture of the King and the Duke of Sparta on arrival at Bisley Station. Such excellent use was made of the negative, that before his Majesty had reached the thousand yards range, Mr. West's staff had printed the plate on picture postcards, and they were speedily selling by hundreds. Other up-to-date features were the printing of all notable events at the meeting as the day progressed, as well as photographing the King's prize-winner, Armourer-Sergt. Comber, and selling the picture before the camp broke up.

THE Newry Agricultural Society held their exhibition on August 8 and 9. A photographic section is included, and cash prizes are offered; the district in which the show is held is very rich in typical Irish scenery. It is near Warrenpoint and Rostrevor, and on the other side is Carlingford, with its numerous old ruins of castles and abbey. All communications connected with the show should be addressed to the Secretary, Mr. J. M. King, The Mall, Newry, Ireland.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes."

The following applications for patents were made between July 17-22, 1905:—

APPARATUS.—No. 14,659. Improvements in or relating to photography and the apparatus required therefor. Ernest Henry Saniter, Strafford Villa, Moorgate, Rotherham, Yorks.

CAMERA.—No. 14,954. New or improved photographic camera or apparatus for use with film racks, applicable, also, to other sensitive surfaces. James Alfred Sinclair, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London.

CINEMATOGRAPHY.—No. 15,003. Improvements in cinematographic apparatus. Henry William Joy, 3, Brown Street, Market Street, Manchester.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

REFLEX CAMERA.—No. 18,815, 1904. The invention relates to reflecting cameras, and has for its object to enable the dark slide to be brought nearer to the lens than is usual in this type of camera, and yet to enable the whole of the picture to be seen on the focussing screen, whether a short or long focus lens is used. The invention further relates to means for releasing the shutter immediately after the focussing screen is covered by the mirror, and to means for rendering it impossible to use the focussing screen in a vertical position when the plate-carrier is in a horizontal position, or vice versa. In carrying the invention into effect the mirror is mounted so that its rear and upper end may, when the mirror is released, first move upwards and backwards from the lens carrier, and, when the mirror has nearly come into contact with the focussing screen, it may move forwards. By receiving this motion, the front lower edge of the mirror is moved in a hollow curve, thereby enabling it to pass the lens-carrier even when the latter is in its rearmost position and when the said front edge of the mirror is carried well forward. The construction of the parts require the eight drawings contained in the specification for its proper explanation. George Russel Nichols, 25, South Norwood Hill, South Norwood, Surrey.

SHUTTER.—No. 18,454, 1904. The forty claims in this specification require the reproduction of the numerous diagrams of the shutter, but the following describes the general claim for novelty:—The invention relates to shutters for photographic cameras, and particularly to that class known as iris diaphragm shutters, embodying a number of pivoted overlapping leaves, and it has for its object to provide a suitable operating mechanism whereby the leaves may be operated for making either time, bulb, or instantaneous exposures, and also for governing the relative movement of the leaves so that the opening formed upon any of the above-mentioned exposures may be stopped or varied in size as the operator may desire. Kodak, Limited, 57-61, Clerkenwell Road, London.

THE Optical Convention will probably meet for the second time next summer, but it is improbable that its activities will be as ambitious as those of June last. The exhibition, which was a large undertaking will not be repeated yearly; but it is thought that the Convention may meet as often as once a year, and confine itself to the reading and discussion of papers.

New Books.

REIGATE AND REDHILL.—A second edition of the Homeland Association's guide to this picturesque part of Surrey has been issued after extensive revisions; 6d. net with ordnance map.

MOUNTAIN PHOTOGRAPHY.—The little German book by Emil Terschak is at once an incentive and a guide to this most healthy and inviting branch of photography, and the second edition, which Herr Gustav Schmidt sends us, has been revised and embellished with additional illustrations. The German title of the work is "Die Photographie im Hochgebirg," and the published price is M2.50.

A **HANDBOOK** on "Colloidon Emulsion" is in preparation by Mr. H. O. Klein, of Penrose and Co., and will deal with this process, as applied to photo-mechanical work in half-tone and three-colour. It is to be issued at 5s.

New Materials.

Chromo-Sulphon. Sold by Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, E.C.

The above is colouring matter in powder for addition to the developing solution, which latter with "chromo-sulphon" as a constituent, may be employed in ordinary day or artificial light. That it is suited for this scheme of "daylight development" we can positively state, for the developer is highly absorbent of the actinic rays, and the plate on removal from it loses every trace of yellow colour in the ordinary course of washing. We have heard little of the dyed developer lately, but whenever the practice becomes talked about, as it periodically has been during the past fifty years, "chromo-sulphon" may be named as a suitable reagent. A three-ounce bottle of the powder costs 9d.

CATALOGUES AND TRADE NOTICES.

"**WATKIN'S Exposure Notes.**"—The sixth edition of this useful little exposure note-book has been published. A new feature has been introduced. The ruled pages are now available either for exposure or for development notes. This is accomplished by printing development "headings" at the foot of each page. The ordinary headings, i.e., "Place and Subject, No. of Slide, Plate, Stop, Light, and Exposure," are at the top, and the entire page can be used for these data if necessary. The development "headings" read upwards and the same divisions of the page can be used or not, as may be convenient. Useful tables and formulæ are also included, and the little book is particularly neat and compact. It is sold at 1s., and is published by the Watkins Meter Company, Hereford.

A new list of Goerz lenses is just issued from the London House 4 and 5, Holborn Circus, W.C. It contains specifications of the performances of the various famous series of Goerz anastigmats and is embellished with bromide and half-tone supplements demonstrating the great optical perfection of the lenses. A series of distinctive names has been adopted for the anastigmats, and the list conveniently summarises the salient features of these—Dagor, Syntor, Pantar, etc. The list, which is altogether a handsome production, and contains a number of notes on the qualities of lenses effective for various purposes, is offered free.

A new collodion paper is now appearing on the market from Messrs. A. E. Staley and Co., 19, Thavies Inn, London, E.C., and is distinctive from the fact that for the raw stock on which it is coated a source of supply other than the Rives factory has been drawn upon—and successfully as far as our experience goes. The paper tones well in the platinum bath, lies flat in the baths, and gives rich brown and black tones. Samples and prices are obtainable from Messrs. Staley.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
	Watford Camera Club.....	Outing to Moor Mill and Netherwyld Farm.
	Orickewold Photo. Society	Trip to Barnet Gate.
	North Middlesex Photo. Soc.	Outing to Godalming.
	Wallasey Amat. Photo. Soc.	Members' Evening.
	Everton Camera Club	Ten Minutes' Papers of Interest to Beginners.
	Devonport Camera Club	Trip to Cranmere Pool.
	Hull Photographic Society	Outing to Westella.

Commercial & Legal Intelligence

At the North and West London Police Court, John Samuel Francis, of Grovedale Road, Holloway, was charged, on a warrant, for obtaining, by means of a false pretence, 2s. 6d. from John William Gray, of Union Square, Islington, with intent to defraud. The prosecutor, a photographer, had employed the prisoner to canvass on commission for orders. It was alleged that he had taken in bogus orders, and received commission on them. The prisoner denied that they were bogus orders, and the prosecutor replied that in some cases there were no such numbers in the streets as those written on the orders. The prisoner was remanded.

At the Louth Police Court, Reginald Innes, photographer, of Freeman Street, pleaded guilty to Sunday trading, and was fined 7s. 6d., inclusive of costs. The shop, said the constable, was next door to a chapel.

MATTHEW KEDDIE MACKENZIE and Miss Margaret Gemmel (Mackenzie, trading as Mackenzie and Co.), photographic dealers and photographers, both of 50, Grove Road, Eastbourne, attended at the Eastbourne Bankruptcy Court on Tuesday of last week to undergo their public examination in bankruptcy, before the deputy-registrar (Mr. J. B. Compton Coles). The case was adjourned.

The Progress Photographic Company, the style under which Mr. George Garett Charles conducted the publishing, wholesale, and export photographic department of his establishment at his premises known as the Progress Steam Works, in Eden Street, N.W., were completely gutted by fire on July 25, the entire set of buildings (five in number), stock, plant, etc., being entirely burned down. The losses are considerable. We are desirous to intimate that any communications, until the works are rebuilt should be addressed to Mr. Garett Charles's Studio, 49, Acacia Road, Regent's Park, N.W.

THE PROPOSED POISONS BILL.—It is stated on good authority that there is now no probability of there being introduced during this Session of Parliament the Bill with reference to the sale of poisons, which had been undertaken on behalf of the Government, by the Lord President of the Privy Council. The shareholders in "Drug Stores" limited companies will not grieve much over this we imagine.

READERS of "Pearson's Magazine" for August will, perhaps, be specially interested in one article, descriptive of the adventures and air-breadth escapes of one of the Editors of THE BRITISH JOURNAL OF PHOTOGRAPHY. These perils were incurred, we hasten to say, not in the precincts of 24, Wellington Street, but where Atlantic breakers make rude sport of life and limb, on the stormy coasts of Cornwall and the Scillies. The writer of the article has a good deal of interest to say on the wave photography of F. J. Mortimer, though, perhaps, those who have not been down to the Scillonian sea with a camera, will credit him with introducing more sensationalism into his description of the sport than it deserves. Such critics are asked to reserve judgment until they have hunted big waves.

News and Notes.

THE Royal Meteorological Society.—The Council of the Royal Meteorological Society are desirous of advancing the general knowledge of meteorology, and of promoting an intelligent public interest in the science. They think that these ends can be most readily attained by means of lectures delivered in connection with scientific societies and institutions in various parts of the country. The Council have now appointed a lecturer, who is prepared to deliver lectures on meteorological subjects—e.g., how to observe the weather, weather forecasting, climate, rainfall, thunderstorms, meteorology in relation to agriculture, health, etc. The lectures will be illustrated by lantern slides from the large collection in the possession of the society. Societies and institutions wishing such lectures will be expected to pay a moderate fee and to defray travelling expenses. The Council are willing to arrange for exhibiting at the gatherings of local scientific societies, institutions, or schools, a collection of photographs, drawings, diagrams, and charts, illustrating meteorological phenomena, and of various patterns of instruments used for meteorological observations. They would also, if desired, lend and fit up a complete climatological station for exhibition, showing the necessary instruments in position and ready for use. The cost of transit and the expenses of a member of the staff in fitting up and superintending the exhibit would be borne by the society or institution inviting the co-operation of the Royal Meteorological Society. The Council are further prepared to lend sets of lantern slides, illustrating meteorological phenomena and instruments at a small charge. Further details on the subject may be obtained from the Assistant Secretary, Royal Meteorological Society, 70, Victoria Street, S.W.

PICTURE POSTCARDS.—A return which has just been issued by the Postal Union for the year 1903 contains some interesting items, especially with regard to the extent to which postcards have ingratiated themselves with the public. It appears from this return that in the matter of postcards the German Empire heads the list with no fewer than 1,161 millions posted there during that year. Even the United States, whose population is about one-half in excess of that of Germany, can boast of only 770½ millions of those missives. Great Britain comes next with 613 millions. Japan, which previously used next to Germany most postcards, is now fourth on the list with 487½ millions. The inhabitants of Germany alone, therefore are now availing themselves of nearly as many postcards as the United States and Japan together. Other countries are greatly left behind in the race; not one of them reaches the number of 300 millions. Individually there came, in millions, upon Austria, 291; the East Indies (British India), 254; and Russia, 114. All the rest show a number of less than 100 millions—namely, Belgium, 63; Denmark, 6; France, 70; Spain, 13; Hungary, 88; Italy, 85; the Netherlands, 59; Norway, 5; Portugal, 11; Sweden, 43; Switzerland, 53. As to letters, however, the United States is far ahead of all other countries. The total number of letters posted there during 1903 was 4,109 millions. Great Britain follows in its wake with 2,597 millions, and then Germany with 1,648 millions. The said three countries together have, therefore, each posted upwards of one milliard of letters. France counts for over half a milliard—namely, 844 millions of letters. With less than half a milliard are Austria with 464, Belgium with 104, Spain with 136, Hungary with 127, the East Indies with 258, Japan with 208, Norway with 32, the Netherlands with 86, Russia with 349, Switzerland with 94, and Sweden with 81 millions.

Le Dernier Cri in the lay press on photography! "Simplex," in a Midland journal, disembowels a reducer from the "Photographic News" of 1868, and offers it as "quite reliable and effective for gelatine papers." It is a solution of potassium cyanide, and we are afraid it has no particular claim to disinterment.

Correspondence.

* * *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

THE ALLEGED "FORGERY CHARGE."

To the Editors.

Gentlemen,—With reference to our publication of the above charge brought against me, and now withdrawn, I beg to state that no one regrets more than myself that further evidence in this case had not been gone into. It would have been conclusively proved that the charge was altogether a false and vindictive one. It was not a question of forgery at all; it was merely a question whether I had or had not the right to sign my brother's name. I certainly produced evidence that by the existence of two powers of attorney, one a general one, that I had the right to act as I did. I have signed a great number of share certificates, transfers, and agreements in the same manner as I signed the Bill in question without taking any trouble to imitate my brother's signature in particular. Without any desire to run my own brother down, let it be said that had it been forgery he would have shown me little mercy! The prosecutor, Mr. H. H. F. Hyndman, insisted on my signing a document (now in court) which would have given him absolute control of the whole business, and which I refused to sign, as well as the secretary of the company, whereupon Mr. Hyndman swore at me, and our friendship was at an end. Needless to say, that on Thursday last my solicitor already issued and served a writ on my behalf on the prosecutor, claiming damages for malicious prosecution and wrongful imprisonment which I have suffered. Surely it must be quite obvious to any business man that if my name was considered good enough to figure prominently as managing director, inventor and patentee of a valuable process, in the prospectus of a company with a capital of £120,000, as issued on July 8 last, of which £60,000 is to be raised from the public, and as a large shareholder, my own name would have been good enough for one of my co-directors (the prosecutor) on a bill for £100, without any need to forge my brother's name or intent to defraud! It is no doubt for this reason that the magistrate found as he did. I shall thank you if in fairness to me you will give a little space in your esteemed paper for this.—I am, etc.,

F. ARBLE,

Managing Director, Metotype Co., Ltd.

82, Cavendish Road, Harringay,
July 30, 1905.

THE FREE ENLARGEMENT IN SOUTH AMERICA.

To the Editors.

Gentlemen,—You will see by the newspaper I mail to-day that Tanqueray and Co. are advertising their "free portrait" in the newspapers of this city. They have been sending circulars by post for some time back to private families. A gentleman some eight months ago showed me a circular and acknowledged that he had been "done" by this firm,—I am, dear Sirs, yours truly, an old subscriber,

J. FITZ-PATRICK.

Calle Rincón, 176, Montevideo,
July 8, 1905.

[The advertisement is in the style with which we are unfortunately familiar, and we hope that our correspondent will be able to convince his public of the fraudulent character of the business.—EBS., B.J.P.]

QUALIFICATION BY EXAM?

To the Editors.

Gentlemen,—Your remarks in the last week's B.J. on certificates and examinations are what I can cordially endorse, for I have had good reason to do so, having once taken on a man who according to the certificate ought to have been able to have done pretty nearly everything, and so he could if he had a year to do it in, and all the stock of a photographic factory to mess about with. But for turning out work on a pretty close time limit and with a narrow margin of wasters, give me a chap who has it in him, and who has had reasonably good training in a well-ordered establishment. In all the instruction in photography which is given I would like to see more attention paid to the practical requirements of a professional business. It is not often that one has trouble which needs a man on the place with a knowledge of chemistry, but every day and all the time we need that quality in our assistants, which is half technical and half commercial, and which is never found in the scientific dabbler who can frequently score brilliantly in an examination. I enclose my card, and remain yours truly,

OLD PROPRIETOR.

July 31, 1905.

FRENCH COPYRIGHT LAW.

To the Editors.

Gentlemen,—I have been much interested in the two cases of copyright law in France which have recently appeared in your columns, the latter under "Ex Cathedra" last week. It would seem that photographic copyright law is one of the things that they do not do better in France. Apparently a photographer has to establish his position in public estimation before he can claim any protection under an act which is framed in the interests of artists only, and does not benefit the photographer until he has proved his title to be classed among artists. It is scarcely necessary to point out the unfairness of this law to the young photographer who has still to make his name. Your artist has copyright because he is an artist, but the struggling photographer, forsooth, must wait until the public distinguishes between his work and that of the man on the other side of the road, who remains "only a photographer." It would be interesting to know, for the satisfaction of some of us who have fancied that French law meant justice, whether a painter must likewise produce proof of his artistry before he can claim protection in his works, but from my reading of the French Law of Copyright I take it that he has no need to do so. I hope the day is far distant when such invidious distinctions will be made in this country,—Yours truly,

ANGLO-SAXON.

Plymouth, July 30, 1905.

J. H. DALLMEYER, LIMITED, makers of the famous "Dallmeyer Lenses," hitherto represented in America by Anthony and Scovill, are stated by "The Photographer" to have entered the American market direct, and to have engaged the services of Mr. F. G. Burgess, late of the Rotograph Company, and previously the travelling salesman of C. P. Goerz. It is the intention of the firm to ultimately open offices in New York City, though for the present Mr. Burgess intends to make a trip throughout the United States and Canada.

"JOHANNES JAEGER, LIMITED," of Stockholm, have, from July 1, taken over the photographic studio and art publishing business, founded in 1860 by the court photographer, Jaeger, and, since 1890, under the management of Mr. Wolfenstein. The managing director for the new company is Mr. Albin Roosval, editor of "Fotografiska Tidskrift."

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

J. Lawrence, "Cambridge," Farnborough, Hants. Photograph of King Edward VII. Saluting.
 V. Catling, 19, Bertram Road, Bush Hill Park, Enfield. Photograph, Group of 1st V.B. Middlesex Regiment (D.C.O.), "P" Company.

REDEGAR.—1. Mr. C. F. Cross, 4, New Court, Lincoln's Inn, W.C. There is no fixed scale of charges. 2. We do not know the address. If we can be of any service to you we shall be pleased. Perhaps you would like to give us a call.

UNMOUNTED BITUMEN.—Re reply to correspondent "A" in current issue. It is more than probable I am under a misapprehension, as you say, but I have upon several occasions read of sensitive bitumen or asphalt used for etching without being able to find out the sensitiser. I understood, however, that it was bichromate, as parts were washed away as in the carbon process, but could not understand how the bichromate was rendered soluble for mixing with the bitumen. The enclosed cutting, taken from an old "Annual" of, I think, 1891, prompted me also to follow the matter up, as I am much interested in it. However, I should be grateful, as a reader for eighteen years, for any information as to an easy method of sensitising bitumen for etching, or information as to any book which treats of the subject.—A.

This matter is referred to under "Photo-Mechanical Notes."

QUESTIONS ON PHOTOGRAPHIC CHEMISTRY.—I should be much obliged if you could inform me, through your "Answers to Correspondents," what the standard works are on photographic chemistry, and publisher's name.—T. E. H.

"The Chemistry of Photography," by R. Meldola. MacMillan.

"Chemistry for Photographers," by C. F. Townsend. Dawbarn and Ward. 1s.

NEW BOOKS.—I wish to take popular views in different towns in the counties of Sussex, Surrey, and Kent. Would you be kind enough to tell me if there is any book published giving the most important views in each town that are saleable and

popular in each particular district? It would be a great help and saving of time to me if there is a book of this description.—VIEW FINDER.

Your request certainly does not lack candour, but we should have thought a prospective publisher of views would know of the material at present on the market. Most of the large photograph publishers issue sets of views or of postcards, or you will find a selection of the best views in most of the guide books to the various localities in the "Homeland" guides, for example.

EN AVANT (and Others).—In our next.

RETOUCHING, ETC.—Can you kindly tell me (1) how to fill in holes and scratches in negatives so that there will not be the slightest trace of them in the finished print? The negatives are varnished, but the holes and scratches are right through the film, leaving nothing but bare glass. Brush with water colour, also the scrapings of old negatives in acetic acid, have been well tried, but without success. Neither method allowed of the exact density at the first application; while if a second coat of colour was applied it disturbed the one underneath, or else showed on the finished print. (2) Is there any simple method of taking a quick proof at night other than by the bromide development method? I am in diggings, and find proofing by the bromide method to cause inconvenience to my landlady, although the negatives have to be perfect to print from in the morning.—WORRIED.

(1) It is a matter of skill and practice, and you cannot expect to become proficient at once. Brush and colour is the usual method, and perhaps it will be necessary for you to touch out the scratches, etc., more deeply than the surrounding negative, and then to work up a print from the negative in which these markings will be slightly lighter and comparatively easy to match. A second negative is finally made from the print.

(2) We can only suggest one or other of the "gaslight" papers, such as Velox.

COPYRIGHT.—Last Sunday I took an order to photograph an interior of a bar of public house. On submitting the proofs (untoned) they were objected to, saying they were not satisfactory. Leaving the house with the promise of taking them again, I went into another public and showed the proofs to landlord, who thought them excellent. On arriving home I received a letter from my clients expressing their non-approval of showing them (some busybody having told them), and wishing me to destroy them. Whose property are they? They have not paid for them. How would you act in the case?—F. L.

The copyright belongs to the landlord who gave you the order. If he does not pay for the work you have done you can sue for the money. But you cannot make use of the negatives without rendering yourself liable to action.

RETOUCHING (General Assistant).—It is impossible to state your probable salary upon the evidence of a single print of an easy subject, and we wish inquirers would make a note of this reply. Three unretouched prints and three retouched should be sent. Let one be of an aged person with character and wrinkles for preference; the next a young man or woman; and the third a child study. All to be toned and fixed and made on glossy paper to show the detail. These would display the ability to differentiate the treatment between youth and age, and would serve us as a fair guide; but even then the query as to salary is almost useless, and we would rather not reply to it. So much depends upon the personality of the applicant, the years of service, and class of experience, and the feeling of the employer in the matter. Our replies to indifferent workers may

set a value upon those of a higher grade that would be unfair, and tend to lower the general rate of wages. Your retouching for mere fineness is very good, but you remove the shadows unduly, and so flatten your effect.

A. L.—(Asnières).—We are obliged to you for your notes.

RESITTINGS (Country Photo).—The subject of your letter is dealt with in "Ex Cathedra."

FROSTING FOR GLASS.—In page 718 of 1905 "Almanac," Mr. H. N. King recommends "Vitrolite" as a frosting for glass, and mentions that it may be obtained from "the well-known" firm of Walter Carson and Sons, but gives no address. I should be much obliged if you will kindly give me the address.

—W. H. R. K.

Grove Works, Lombard Road, Battersea, S.W.

FIXING TROUBLES.—I have had considerable trouble with my hypo bath lately, my negatives will not fix some days, even when left in hypo bath for half an hour or even more, one edge or corner remaining unfixed and blistering. Until this has happened I have been in the habit of developing a batch of negatives while the last batch fixed, and have never had to wait for the first batch to fix; but now it means a great loss of time as well as many spoilt negatives. I make the hypo very strong. I can only put it down to one of the following reasons:—1, hypo being too strong; 2, hot weather; 3, poor hypo; 4, faulty plates. Any advice you can offer will be greatly esteemed, as I am at my wit's end what to do.—

WORRIED.

It is quite possible that the first cause is the real one. It is a pity you do not tell us the strength of your bath, but it should not be more than 8 oz. to the pint, better 6 or 4 oz. The hot weather may have had something to do with it, by causing the bath to become stronger by evaporation. You should keep it covered when not in use, or pour off the bath into a jar. Nos 3 and 4 are improbable. Try working with a bath 6 oz. per pint, and let us know if your troubles do not disappear.

FINGER PRINTS.—I should be greatly obliged if, through the medium of your paper, you would inform me the best way to photograph finger prints on glass and wood, etc.; if special treatment, plates, developer, exposure, etc.? I should think it would be interesting to most photographers. I have some to do but am quite ignorant how to get about it.—N. BARRY.

We have had no experience in this work, and can only suggest that the impression should be intensified by dusting some impalpable powder, such as bitumen, over it. The surplus having been dusted off, that adhering to the impression could be fixed by heat. In the case of finger prints being made, we may quote from Dr. Francis Galton's directions as follows:—Ink a piece of glass plate with printer's ink by means of a printer's roller, applying the ink very uniformly and thinly. The coat of ink should be so thin that when the inked plate is held between the eye and the light, its tint should be of a smoky yellow, very far from black. Press the finger first on this inked glass and then on a porcelain palette, such as is used by painters in water-colours. The extreme whiteness of the palette contrasts well with the impression upon it, and makes photography easy.

S. HORTON.—Will you kindly give me your opinion on the following questions? I give an order to a publishing firm for postcards of the town and districts, and to save them the trouble and expense of making negatives, I sell them prints from my own negatives at 2s. each. The postcards are to bear my name,

and as I do not want the whole batch at once, they agree to let me have half of the order at first, and to hold the remainder until I require them. I now find that they are selling these cards to a rival firm in the town. Have I any redress? These prints were not copyrighted at the time, but some of them have been copyrighted since.

We do not quite understand the matter from your letter where you say you sold the prints to the firm to execute an order for you. If you gave an order on the terms you say they had no right to sell the photographs to your rival unless, indeed, you did not take the prints they held in stock for you within a reasonable time. You can prevent your rival from selling the photographs you have made copyright, and obtain damages for their sale from the time of registration, if you can prove you have sustained any.

RETOUCHING (Reply to C. F.).—1. Your retouching is second-class only, but might easily become first-class with a little effort and under direction. Balance shadows under eyes to better effect, and grade out to face line with nicer definition—increase your high lights, but do not leave them lonely or too marked. 2. For your retouching only you would not receive more than 30s. per week; but much depends upon your speed, which you do not state. 3. With regard to your operating, it is fair, but you are using a villainous background that plays havoc with the head—which should be kept clear for such a subject.

DEATH OF WALTER E. WOODBURY.—We see announced, in the American papers, the death of Mr. Walter E. Woodbury from fever contracted in Panama, where, at the time of his death, Mr. Woodbury was acting as assistant editor of a daily paper. Mr. Woodbury was well known in photographic circles in Europe and America. He was in Germany at the time of the rise of gelatine printing-out paper, and is credited with the coining of the word "Aristotype." He wrote the first handbook on gelatine printing-out processes. During his career in America Mr. Woodbury was with the Velox Company, and for some years edited the "Photographic Times" and the "American Annual of Photography" for the Scovill and Adams Company.

THE employees of Art Printers, Limited, Bristol, had their annual outing on Saturday, July 29. The party drove to Badminton by char-a-banc; a stop was made at Chipping Sodbury, and lunch was taken at the Portcullis Hotel. On arriving at Badminton the party visited his Grace the Duke of Beaufort's kennels, stables, and grounds, after which cricket and tennis were indulged in, and the party left at 7.15 for the drive home, which was very pleasant, songs being rendered in first class style, and received most heartily.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION, Post Free.

(UNITED KINGDOM AND THE CHANNEL ISLES).

One Year ... 10s. 10d. Half Year ... 5s. 5d.

Quarter Year ... 2s. 9d.

Places Abroad (One Year) ... 13s. 0d.

It may also be obtained from all Booksellers, Photographic Dealers and Railway Bookstalls.

EX CATHEDRA.

Tanquerey It would seem as if M. Tanquerey, of the Société Artistique des Portraits, was not finding the European market quite responsive to his cajolleries. The last we heard of him was from a correspondent in Ceylon, and this week our reader in Johannesburg informs us that all the firms were receiving the time-worn offer of the free argument. We trust our estimable friend of the Rue Turin is not falling on bad times, that the "free argument" fraud is beginning to lose its freshness, and that he may be forced to seek some other vocation for which the chief qualification is an unbounded confidence in the gullibility of the human race. It would naturally be as if these forebodings proved to be true, and if, as seems to be the case, we have ourselves in some measure contributed to the present circumstances. We can assure Tanquerey it has always been a pleasure to us to make business known.

Rising Price of Platinum. The price of platinum has undergone a good deal of fluctuation, but has steadily risen of late years, notwithstanding an increase in the production of the precious metal. The chief source is the Perm district of Russia, where some firms are engaged in platinum mining. According to a report in the "Chemische Industrie" on the present condition of the business, the production rose spasmodically in 1901 from 310.7 to 389 pounds (the pound equals 15.43236 ounces). But this advance has not been maintained, and, for one thing, the ore has proved slightly poorer in platinum, and, for another, that under the peculiar conditions of the business, mine owners have no inducement to increase the supply, and, therefore, as the Russian mines are by far the most important source of platinum for the whole world, there is no reason to anticipate any

reduction in the cost of a material of such importance in photography. Excepting revolutionary changes which the modern scientific alchemist may produce, the immediate prospect is for platinum to become dearer rather than cheaper.

* * *

Who Took the Photograph? We read in the Manchester papers that the Queen has been presented with a photograph, specially taken for the purpose, of the recently-established child's cot in the Northern Hospital. But we do not see any mention of the photographer to whom the work was entrusted. In an event of this kind, which is of some considerable public interest, it might reasonably be expected that the name of the firm undertaking the work would appear. It probably would in the case of a jeweller or a confectioner doing anything on such an occasion, and though the question may seem a paltry one, small news items of this description keep a photographer's name before the public, and it is to his interest to endeavour to obtain such acknowledgment of his work in the Press. Usually it will not be difficult to achieve this end through the parties from whom he receives his commission, or from the newspaper people.

* * *

Pirie MacDonald. Among the Transatlantic visitors to London has been Mr. Pirie MacDonald, "Photographer of Men," New York, an interview with whom appears on another page. Mr. MacDonald is a conspicuous member of the group of twenty or twenty-five individualist photographers of New York. He is a "photographer of men" only, and strictly adheres to that self-description in the pursuit of his profession. Your American worker with ideas and personality is more often than not a first-rate man of business, and one does not want to know Mr. MacDonald very long to discover that the alert, clear-cut business faculty is merged with the artistic half-philosophical cast of mind which aims at character studies of sitters as distinguished from facial delineation. How a man advertises is no bad guide to his grasp of a business, and here we have a photographer of men announcing his studio in the ladies' papers, on the practical basis that man comes never to a studio, but is driven there by his sister, wife, or sweetheart. And the matter of the advertisement is just that which rivets attention. There is Pirie shown putting all his weight to close the door of his studio. Over the fanlight is inscribed "Pirie MacDonald, Photographer of Men," but through the slit of the door is visible a surging tide of women struggling for entrance. To take another. A dude of the dudes, flabby and effeminate, is shown in course of sudden ejection from the studio, and, as before, the letterpress

reads only: "Pirie MacDonald, Photographer of—MEN!" Mr. MacDonald recently organised, and became the first president of, the Professional Photographers' Society of New York, a body with aims allied to those of the P.P.A., and already proving a considerable strength to the professional photographers in New York State.

* * *

The Outdoor Portrait Photographers, of all men, Life.

ought to see to it that their hours of leisure are spent as much as possible in the open air. Even a photographer who does not actually spend much time in his dark room gets none too much fresh air in the course of the working day, and some form of outdoor sport, which braces mind and body, is an essential to his well being and an actual business asset. There are precedents in the profession which argue for the truth of what we are saying. One West End photographer at least can be seen every morning taking his early dive into the Serpentine, and he finds the practice a sure means of keeping up to concert pitch. Golf has several distinguished exponents, and among other advocates of active outdoor exercise we might name a well-known Hull photographer who is captain of a cycling club, and does good, not to himself only, but to others whom he introduces to the byways of the East Riding. Our advice to the photographer is to guard his leisure from the claims of business, and to set apart as much of his free time as he can for exercise in the open air. His work and his business will be all the better for it.

* * *

The Portrait and the Sitter.

When a number of negatives are taken at a single sitting, the photographer usually feels that there is one which embodies his conception of the subject better than the others, and is the one which he would prefer the sitter to take. Very possibly the choice of the sitter and the sitter's friends will be quite different, as their decision is based on likeness above all things—a fact, of course, which the photographer should keep ever before him. Nevertheless, it may often be desirable to "force the client's hand"—to borrow a phrase from the card prestidigitateur—and there are ways and means which may be adopted to bring the choice on the favoured portrait. The latter can be printed "just so" in every respect, while others are kept a little under or over printed. The portrait to be "forced" is produced in perfect finish, immaculate in point of surface and mounting, while the others may be let fall a little below the standard, or sent as avowedly rough proofs. Unknown to the customer, a particular print, embodying some distinctive feature of the photographer's work, may be made acceptable above its fellows.

PRINTING PROCESSES.—X.

ALBUMEN PAPER.

The sensitising of albumen paper was fully described on page 563 *ante*, but paper so prepared will not keep more than a day or two, and therefore it is best to use up all of it on the day of sensitising. The addition of citric or of tartaric acid to the silver bath enhances the keeping qualities of the paper, but the acid retards toning, and introduces difficulty in obtaining deep, rich tones. The whiteness of the paper may, however, be retained for some days by storing it between sheets of pure blotting paper saturated with a solution of carbonate of soda and afterwards dried. If the pads of the printing frames be similarly treated, prints not finished one day may be completed on the next without deterioration.

The conditions under which the paper is printed have an influence on the toning of the print, particularly at this season of the year. If the printing frames and their pads become abnormally dry, as they may do if stored, when out of use, in a very hot and dry place, the prints when taken out of the frames will have a rusty brown colour, be mealy in appearance, and also refuse to tone to anything beyond a dirty brown. For this reason the frames, when not actually in use, are best kept in a room of normal dryness. In the last article it was mentioned that fuming with ammonia finds more favour in America than here. This may be because the atmosphere of this country is always in a moister condition than that of the States.

In printing, the prints should be made somewhat darker than they are to be when finished—the deeper the tones desired the darker should be the printing. It should be kept in mind that some toning baths reduce more than others. Prior to toning, the prints must be washed for ten minutes or so in three or four changes of water to remove the free nitrate of silver. The first and second waters should be saved, as they contain a good quantity of silver, especially when the paper is sensitised on a strong silver bath. After the last water ceases to be milky the prints are ready for toning. The toning baths that may be used for albumen paper are almost innumerable; any of those given for P.O.P. on page 524 may be employed. The one most in favour with those who employ albumen paper is the acetate bath; indeed, it is probably more used for the purpose than all the other toning solutions put together. Here is the formula for it:—

Acetate of soda	30 gr.
Water	8 oz.
Chloride of gold	1 gr.

This must be made up at least twenty-four hours before it is to be used, otherwise it is liable to yield mealy prints. This bath can be used over and over again if more gold be added as it becomes exhausted, but the gold must be added some eighteen or twenty hours before it is again employed. Very occasionally a little more acetate will be required. The bottle containing the bath should not be exposed long to the light, otherwise the gold will become reduced. This bath is admirably adapted for producing the tones that were known some years ago as the Payne Jennings red by stopping the toning at an early stage. With deeper toning it gives rich purple browns, and, with strong negatives and deeper printing, purple blacks may be obtained. It may as well be mentioned here that the tone yielded by any bath is largely dependent upon the negative. If deep, rich tones are desired, the negative must be of a vigorous character, so that the deepest shadows become strongly bronzed in the printing. Thin and feeble negatives are useless for deep-toned prints. A good bath for cold tones is the following:—

Carbonate of soda	4 gr.
Water	8 to 10 oz.
Chloride of gold	1 gr.

This bath should be made up shortly before use, as it will not keep for more than an hour or two. Here is a bath that found much favour some years ago with those who liked cold tones. It is known as the lime bath:—

Boiling water	8 oz.
Chloride of gold	1 gr.
Chalk or whiting	30 gr.
Saturated solution of chloride of lime ...	2 minims

When cold, the solution is decanted from the chalk sediment, and it is then ready for use.

With this bath considerable over-printing is necessary, the chlorine has a reducing action on the image. Here is another form of lime bath that is preferable to the above, inasmuch as it has practically no reducing action on the print, therefore little or no over-printing required. Furthermore, a stock solution of it may be kept. The formula is as follows:—In a 10 oz. bottle put a few ounces of distilled water and add 15 gr. of chloride of gold. Drop in a piece of blue litmus paper, which will be turned red. Add lime water (not chloride of lime) till the blue colour of the paper is just restored. Then add 2 dr. of fused chloride of calcium, and make up the bulk to 7½ oz. of water. For use, take half an ounce of this to 8 oz. of water. This bath, like the acetate, can be used over and over again by the addition of more of the stock solution, and that may, if necessary, be added while the prints are toning without injury to them. The stock solution as well as the used bath should be kept away from the light, to avoid spontaneous precipitation of the gold.

Another good toning bath, that is much liked by me, is:—

Borax	20 gr.
Water	8 oz.
Chloride of gold	1 gr.

This yields good purple-brown tones.

There are many other baths, as well as modifications of those given, that can be used for albumen papers, but the above are the most popular ones. It may be well to point out here that all of them will yield good warm brown tones, if the toning is arrested at an early stage, then the colours with all of them will be very much alike. It is in the deeper tones that the effects given by the different baths are most noticeable. In toning albumen prints the colour must be judged by looking on them, and not

through them, as with P.O.P., and the toning should be stopped as soon as the desired tint is reached, or a little before. It should also be mentioned that with highly albumenised papers, such as the double albumenised, deep blacks or purple-blacks are much more difficult to obtain—whatever bath may be used—than with less albumenised ones.

After toning, the prints are washed in one or two waters and, if many are dealt with at a time, it is well to put them, when removed from the bath, in a very dilute solution of salt, to stop further toning action. After another rinse in water, the prints are fixed in:—

Hypo-sulphite of soda	8 oz.
Water	40 oz.

In this they should remain for fifteen minutes, being kept in motion all the while by turning them over and over. If they are allowed to stick together stains will be the result. After fixing, the prints must be well washed in several changes of water, being kept in motion all the while. If the prints are washed in a dish, the best way is to keep them turning about, by hand, in the water for six or seven minutes, and then pour it off and rear the dish up on end, with the prints sticking to the bottom, to drain for two or three minutes. The dish is then refilled with water and the operations repeated. In this way the washing of quite a large number of prints may be thoroughly done in an hour or a little more—that is, if the fixing has been complete, i.e., the hypo salts of silver converted into the freely soluble state. Warm water may be used to facilitate the removal of the hypo without injury to the pictures, and this practice is frequently adopted. At the fixing and washing stages, with some papers, blisters may arise. This subject, as well as the manipulation of ready-sensitised papers, will be dealt with in the next and concluding article on albumen printing.

“PHOTOGRAPHER OF MEN.”

is characteristic of the American photographers, of those, that who are at the head of their profession, that they should come over to Europe to look after business, or to seek ideas for the New world, in the ancient picture-galleries of this country and the continent. Among the visitors who have just left London was Pirie MacDonald, “Photographer of Men,” of Wall Street, New York City, with whom a representative of the BRITISH JOURNAL OF PHOTOGRAPHY obtained an interview, embodied in the notes which follow. Another well-known New York photographer who has just over here is Core, also of New York. Like Mr. MacDonald, he is a specialist and an individualist; and some account of how he has associated his name throughout America with the photography of children will appear next week.

He was not always a photographer of men only. A few years ago he had a snug business in Albany, New York, where he made portraits of anyone who came along, from babies upwards. In those days he was known throughout the American fraternity as a great supporter of the Photographers' Association of America. He was always much in evidence when any hard work needed to be done for the benefit of the profession. It would be unjust to any excellent men to say that he was the heart and soul of the annual meetings—but he was one of the many “hearts and souls.” When, however, it came to exhibiting, he was *facile princeps*. In all classes of portraiture, from miniature upwards, he was used to securing the premier place in the exhibitions.

Pirie MacDonald was everywhere known as a good photographer, and a prince of good fellows.

A Prophet at Home.

So much for his fellow craftsmen. In his own city of Albany he proved that a prophet might have honour in his own country. It is one thing to produce exhibition winners, and quite another to produce everyday work worthy to rank with exceptional efforts. But wherever one went in Albany homes there were photographs dotted about which were unmistakable. The ordinary output of the studio was as distinctive as its exhibition pictures.

From a business or social standpoint what could possibly be better? Mr. MacDonald photographed and cycled, and debated, and lived the strenuous life of a man overflowing with vitality. But there came a day when he squared his broad shoulders, and set his firm jaw, and declared he would have a chance. He sighed for a new world to conquer. His friends have wasted much brain energy in devising some plausible reason for this change. There is a legend to the effect that an irate female customer stunned him with his own lens, and that since that fatal day his nerves have given way at the swish of a skirt. But there is no scar to substantiate the lens story, and the man's nerves are equal to all emergencies. It was sheer love of tackling and overcoming new conditions which sent him from the Albany studio into the swirl of New York.

A Photographer of Men

New York is a city—photographically—of individuals and of specialists. Few people open there successfully unless they do

distinctive work. The rank and file who do "the usual thing" are not of much account. Pirie Macdonald did not do as others have done—he did not open on Fifth Avenue. He made men his specialty, and he went where they foregathered. His studio is high above the street—Wall Street—in a many-storied business building, in the heart of the busiest hive of wealthy men that the world knows. And the results have justified the enterprise.

He Takes a Holiday.

New York has an annual "hot season." For several months in the summer all who can do so flock to Europe or the seaside, or to the mountains. This summer Pirie has come to England, and we ran him to earth for a few minutes just before he sailed for home. We were anxious to learn a little first hand about his work, and he was ready to talk on any subject except that one. He would warm to photography in general as a topic. He has no pessimism about the "fatal facility" of camera work. Only those who have gone through the mill know how the mere chemical and mechanical difficulties of the past have chilled artistic enthusiasm. Photography is no mechanical tool, but a medium whereby an artist may express himself. The younger generation, or at any rate the successful part of it, is becoming less and less artisan. Photographers, while continuing to make pleasing combinations of line and texture, are becoming closer students of character. Undiscerning folks may talk of nature-rubbish. There are enough of harsh sounds in nature; but the harmony of music is not nature—it is art.

About Prices.

"Prices? Well, English photographers have not much to complain of in that respect. Certainly some American photographers get prices which are away up; but so do some English photographers. The men on this side who get a guinea a dozen for cabinets are doing similar work to that which may be obtained for five dollars a dozen in New York. And, after all, there is the other side to high prices. They are of little use unless accompanied by a sufficient volume of business. And in this vital detail the advantage may be with the Englishman."

"But we hear a good deal about go-ahead American business methods. How do we rank?"

Pirie Macdonald laughed. "Don't you believe it. There are good business men on both sides, but some of your most successful men are eye-openers to us. There is not much they do not know. The most noticeable difference is in individuality. I could select the photographs of a dozen successful British firms, and, if the names were trimmed from the mounts, would defy anyone to apportion the prints to their respective studios.

In America a man may be doing the most orthodox of home 'old-line' photography and yet his work is distinctive. The successful photographer in England keeps a firm hold of the business end. He holds the cheque-book and employs capable men to do the practical work. In America he is more likely to handle the camera and be the practical overseer, with his palette help at the desk.

"In New York we have perhaps twenty-five or thirty photographers who are doing essentially individual work. Yes, may be that we have a different class of sitters."

A Difference.

"In England you may hear little of an individualist, for the tendency is to become exclusive and to cultivate a select private clientele. But all American workers keep before the public. And your English sitters are more amenable to the photographer. They place themselves in his hands and accept the results he offers as being what his trained judgment considers the best. In America they form more definite ideas of what they want and if the result does not come up to expectations they are not slow to say so.

"I have seen some of the bulkiest work that I have ever come across, here in London. My specialty, as you know, is men. Well, I have seen some portraits of men that have made me envious. They were mostly 10 by 12 heads. They were—lastingly full, rich, strong, soft, at once. And there was flesh—flesh such as few photographers have conceived. Loose in texture, but nothing in them that was outré; nothing that the normal Philistine could object to. Some of our workers develop what we call the 'freak' mania. But these pictures were the sanest of photography, free from tricks and affectations. Such work would go strong in America—would make a big hit. But here the photographer tells me, nobody wants it. I wonder whether you could guess where I found these photographs?"

L'Adieu.

"You are a great believer in the convention spirit. Do you know that we now have a successful P.P.A. on this side?"

He glanced at his watch. "Ah! You must not draw me out of the question of fraternity. Time's up, don't you know."

"Well, at least, you may leave your formula for success."

Pirie laughed. "Work is the formula. But tell the boys not to come to the States to study American hustle—there are several instances of it in your London studios and they need go no further. But if they come over we will try to give them a good time."

THE WEEK IN HISTORY.

Daguerre's English Patent.

For practical purposes photography is almost exactly sixty-six years old, for 1839 saw the birth of photographic processes which could be put into actual use. During the early part of that year, Daguerre had been busy with his negotiations with the French Government, so that although his process was perfected in January or February, if not earlier, it was not until the last week in August that his *modus operandi* was made known. On June 15, as I have already mentioned in the WEEK IN HISTORY, the French Chamber passed the Bill by which he and Isidore Niepce were granted annuities for freely making known their process to the whole world. However, on Monday next, August 14, exactly sixty-six years will have elapsed since application was made in England for patent rights. The preamble to this first photographic patent runs as follows:—

"This invention relates to photogenic drawing or the spontaneous reproduction of images, pictures, or representations of

nature by the action of light; that is, by the process or methods now well known under the name of Daguerreotype. I believe it to be the invention or discovery of Messrs. Louis Joseph Jacques Mande Daguerre and Joseph Isidore Niepce, jr., both of the kingdom of France, from whom the French Government have purchased the invention for the benefit of that country. This invention or discovery was fully communicated to me by a certain foreigner, residing in France, on about the fifteenth day of July in the year One Thousand Eight Hundred and Thirty-Nine, with instructions immediately to petition her Majesty to grant her Royal Letters Patent for the exclusive use of the same within these kingdoms."

Daguerre's patent was set aside by Sir Thomas Wilde in 1847.

Emulsion Washing by Precipitation.

It is just twenty-eight years ago—on Thursday next August 17th—that Mr. F. Wratten, of Wratten and Wainwright, worked out a method of washing gelatine emulsions—or rather his process was first made known on this date in the BRITISH

JOURNAL OF PHOTOGRAPHY. The method was to add alcohol in considerable quantity to the unwashed emulsion, whereby the gelatine and silver bromide were precipitated together, and the alcohol and included water formed a mixture, in which were dissolved nitrates and other salts formed by double decomposition when the emulsion was mixed. This clear liquid collected at

the top, and was eventually poured off. At this time a ready-made emulsion, to be liquefied by the photographer for his own use, was kept in view as much as a ready-prepared plate, and it was for this purpose that the method was put forward quite as prominently as for the coating of plates.

HISTORICUS.

PERSULPHATE EFFECTS WITH FARMER'S REDUCER.

(A communication to the Photographic Society of Philadelphia.)

THE objection hitherto to the so-called Farmer's reducer has been to the tendency of the agent employed to destroy the detail of the shadow parts of the negative while acting upon the high lights; hence the Lumière Bros. introduced the persulphate of ammonia as an agent which would act harmoniously upon the film—that is, would attack the high lights (the dense deposits of the film) in preference to the thin portions. The persulphate undoubtedly is a valuable chemical and in the majority of cases will be found to work effectively; but frequently it is refractory, apparently not acting at all in the line of reduction. Besides, it requires considerable manipulation to insure success and preservation of the negative from subsequent action.

High-light Reduction with Farmer's Reducer.

The writer has found that the ordinary Farmer's solution, the mixture of ferricyanide of potassium and hypo, may be made to act harmoniously upon the film, that is, to preserve the shadows while it reduces the high-lights. Its harmonious action depends principally upon its constitution and mode of application.

Everyone is aware how much more readily a plate will reduce and indeed how much better is the relation of high-lights to shadows when the plate is reduced with the Farmer's solution immediately on removal from the fixing bath after development, than it can be after being thoroughly washed free of the hypo and dried. Indeed it is the practice of many practical workers to immediately reduce the plate after examination from the hypo bath.

Now the reason why the plate (unwashed from hypo) reduces

more harmoniously as regards light and shade when placed in the Farmer's reducer is on account of the hypo on the film having the preponderance. So that if one wishes to secure shadows, the rational way to proceed is to constitute the reducer so that there may be considerable excess of hypo over the ferricyanide of potassium (the red prussiate of potash), for when the ferricyanide of potassium is in excess, the shadows invariably suffer.

The Method—Ferricyanide in Acid Hypo Solution.

The method employed by the writer (who prefers the Farmer's solution to the persulphate) is to reduce immediately after fixing, when possible, making the film acid with acetic or citric acid and then to place merely in a 5 per cent. solution of ferricyanide of potassium—lifting the plate after a few minutes' action to note the progress, for the action must not be allowed to continue too long or the shadows will pay for it.

When it is necessary to reduce a plate which has been thoroughly washed from hypo, the plan is first of all to soak the film in a bath of weak acid, say a 10 per cent. solution, for 5 or 10 minutes, and then transfer to a bath of hypo for another 5 or 10 minutes, and finally subject it to the action of the ordinary Farmer's solution, that is, one constituted with twice or three times the amount of hypo over the ferricyanide solution and made acid by addition of acetic or citric acid sufficient to redden litmus paper.

Intense plates may thus be reduced as effectually as with persulphate and with less trouble of manipulation.

JOHN BARTLETT.

PROCESS WORK IN AMERICA.

I.

AMERICAN process methods do not differ very much from European practice in a general way, and anyone making a tour of inspection round an American photo-engraving shop will be disappointed if it is expected that anything very wonderful will be seen. Here in England, and also on the Continent, we work processes which we originally derived from America, and we employ American-made screens and machinery to a large extent. Such difference as now exists between English and American shops lies, for the most part, in the fact that whereas American workers have changed very little the methods we learnt from them ten years ago, European workers have elaborated both the processes and the apparatus.

A Lack of Progress.

The majority of American photo-engravers seem to know very little of what is going on outside their own country, for they read very little about their craft. As one of their own writers puts it, "The rank and file, 95 per cent. of them, never think of reading anything technical regarding process work; they simply 'plug' along from day to day in a purely mechanical way, grinding out their quota of work without thought as to why or what, and with only a mind for quitting-time or pay-day. Once out of the shop, process is out of mind, and the days slip by without improvement. In a business so full of possibilities, the great bulk of workers are but

day labourers, bricklayers, and hod carriers." The employer is perhaps, equally to blame. In a great many firms the principals are men who have not worked practically in the business, and only know the technical part in a general way. Work has to be got out so quickly, and competition is so keen, that there is no time to experiment with new processes. Certain processes have been found to yield uniform results, and everyone else uses the same, so there is no thought of changing. There is hardly any originality displayed in the equipment and lay-out of the shops, and they are apparently pretty much the same as they have been at any time during the past ten years, except that they have grown larger, and the plant has been duplicated. After you have been shown through one or two representative shops you find little to interest you in the others, as they are all so absolutely alike.

American Process Apparatus.

I certainly did not see in American photo-engraving shops any evidences of that extreme eagerness to "scrap" old plant when it has obviously become worn out or obsolete, as we have so often heard is the regular practice on the other side. If it were so there would have to be a very complete "clean out" in the majority of the photo-engraving studios in the United States. The cameras and stands were for the most part of a rickety, even ramshackle, descrip-

tion, and often the operator has to stick wedges in badly fitting parts to ensure some degree of parallelism. The American operator, or his employer, does not seem able to get away from the idea that the camera is only a "box," and "any old thing" will do so long as you have a decent lens, forgetting that all the good qualities of the expensive lens are neutralised by the imperfections of the camera and stand. The latter is generally a cheap and flimsy construction, roughly put together, with no pretensions to accuracy. Frequently I hear, "We buy the 'lumber,' and have it put together by a carpenter on the premises when the studio is being fitted up." When the stand begins to show signs of decrepitude, as a good many of them already do, it is "fixed up" with wire nails and bits of string. The dark slide, or plate holder as it is called, is usually of the pattern in which the screen is carried along with the plate. If it has a screen-distancing mechanism it is generally a poor makeshift, and so clogged up and rotted with silver nitrate solution that it is impossible to move it. There is just beginning a tendency to adopt the European plan of holding the screen in an adjustable mechanism at the back of the camera, and there are two or three American-made cameras which somewhat distantly resemble European ones. The American makers do not, however, seem to be able to get away from the idea that a process camera must be cheap to be acceptable to American firms, and the result is that they cannot afford to produce a camera with any great degree of accuracy or durability. I am afraid such cameras give the operators a very unfavourable opinion of the European plan of process camera construction. To import European cameras is, however, out of the question on account of the high initial cost, the expense of shipment, and heavy duty, amounting, I believe, to 45 per cent. of the value.

The Skylight Studio.

Daylight is used whenever possible, and almost every photo-engraving shop has its big skylight studio. The photo-engraving shops are generally located on the top floors of tall blocks of offices or warehouses, and in some cases occupy superstructures on the roof. It is not unusual to find the photo-engraving studio on the 13th to 15th floor of some of the older "skyscrapers." That height, however, is somewhat out of date in New York, where a 21st floor is now to be found in several of the buildings; and they talk about putting an extra storey on some of them. The wonder is that the photo-engravers do not have trouble from vibration, for these buildings shake quite perceptibly. However, various forms of spring stands are used, and this probably overcomes the difficulty.

The Gill Engraving Company in New York have held the record hitherto for the largest skylight studio in the States, but in Chicago I found two concerns were having immense skylights constructed, and one of them, on the roof of the great printing house of R. R. Donnelley Sons and Company, was destined to eclipse everything hitherto done. The studio is 85 feet square, and furnishes accommodation for twenty cameras; it is divided down the centre by a row of eleven dark rooms, and there are nine more dark rooms on the south side. These dark rooms are most substantially constructed, and are lofty and well ventilated. A notable feature is that instead of being constructed of matchboard partitioning, a light kind of corrugated and galvanized steel is used. I noticed this in several other studios. The illumination is obtained from the outside, and the windows can be thrown open when the developing is completed. The half-tone work is to be done in the south part of this studio, the glass roof of which slopes towards the mid-day sun. The north division is to be used for colour work, the photographing of commercial objects being done direct from the goods.

Electric Lighting.

Whilst daylight is largely used, arc lamps are always available

for dull days, and in a few cases where it has not been possible to get skylights, the arc is used exclusively. The "enclosed arc" is rapidly superseding the open arc, but I do not think that as good lamps of the former type are in use in America as in England. I believe our lamps are faster, by reason of the longer arc they draw due to the higher voltage they work on. Again, the use of flame carbons for colour work to reduce the exposures through the filters is quite unknown. The mercury vapour lamp was everywhere in evidence, and was well spoken of both for printing and negative making.

Direct Half-tone Work.

It is quite a general practice to make half-tone and colour reproductions direct from the goods, and it was in this line that I noticed the most marked departure from English methods. There are firms in England who make a feature of photographing commercial articles, and even have a studio set apart for it, but in America it always seemed to me that a very large portion of the business was devoted to this kind of work. In several cases there were immense lifts in connection with the commercial studio, by which large machines, motor cars, or similar bulky affairs, could be brought into the studio complete. In the Binner-Wells Company's studio in Chicago, they make a specialty of reproducing cut glass ware and have a special process for preventing reflections by dulling the surface of the glass without impairing the brilliancy of the high-light effects. They also make a feature of reproducing jewellery and other small objects by laying the things out on the horizontal board of the vertical copying stand. The camera is mounted parallel to the board and is provided with a prism, the face of which is turned towards the board, and the whole stand is run under the skylight where direct sunlight can fall upon it. They get very brilliant effects with splendid detail and no heavy shadows. They have given the appropriate name of "sunlight half-tone" to the results. The half-tone negative is made direct from the objects there being no intermediate stage of producing an ordinary negative, making a print and working it up. They told me they were attempting a "high light" method by which the screen in the background would be eliminated.

Colour Work and Collodion Emulsion.

In the studios of the American Three-Colour Company in Chicago, such objects as ties, scarves, etc., were mounted on a large board and the three-colour negatives made therefrom on dry plates. They had not, however, got to the European practice of making direct half-tone with collodion emulsion. This was not for want of trying. They had had experienced men from Europe, but none had so far succeeded in making a commercial success of the process. The same tale was told me in many other concerns, and collodion emulsion was rather under a cloud in America in consequence. The firms could not make out the reason of this ill-success; they thought there must be "something in the air," or in other words the climate was not suited for it. It could hardly be the fault of the men, seeing that some of the European operators had also failed. They thought the dealer who supplied the emulsion did not give them the same kind as that used in Europe, but batches of emulsion were imported from Europe with no better result. The process was accordingly being looked upon as somewhat of a mystery, and one employer expressed the opinion that it could only be worked by operators who were trained chemists; such as he thought were employed in German studios. Notwithstanding, there are a few firms working collodion emulsion successfully, and this deepens the mystery.

The opinion I formed was that the trouble, when it was not due to badly cleaned glass, dirty holders, and the generally sloppy conditions which prevail in the majority of American process dark rooms, was owing to a lack of appreciation as to the result to be

ed at. The operators were disappointed because they could not the precise black and clear cut dot of the wet plate half-tone negative, and the metal printer objects to print anything else. In, the American operator has got the idea that it is a mistake to expose on white paper for the shadow dots, and his reluctance to do it leads to the weakness of his shadow prints. Now, this "washing" with white is regarded in Europe as a valuable aid to production of good negatives, and so long as it is not overdone there can be no possible harm to the gradation of the negative. Done at the commencement of the exposure it overcomes the inertia of the

plate, and it does no more than build up the centre or nucleus of the dot, so that the deposit of silver can be carried on by the regular process of exposure on the original. I showed an operator a sample collodion emulsion negative brought from England, and he immediately exclaimed: "If I could get a negative like that I should be well satisfied." To sum up it seems that where they have failed is through attempting to apply wet plate methods to emulsion.

WILLIAM GAMBLE.

[The conclusion of Mr. Gamble's "Notes on American Process Work," may appear in our issue of August 25.—Eds., B.J.P.]

CONTROLLING EXPOSURE AND DEVELOPMENT IN BROMIDE ENLARGEMENTS.

(A Paper read before the Photographic Society of New South Wales.)

EDITORIAL NOTE.

Systems of exposure of development papers by rule have been frequently advocated, and have, we know, been found of considerable service by their exponents, yet little or no progress has been made towards the wider adoption of such a method in practical work. Indeed, very little has been done to simplify the experimental work—which is a necessary preface to such a system—since Mr. V. C. Riffled's paper on "The Principles Involved in Enlarging," appeared in our pages eleven years ago. Thus, while we are bound to recognise the trial and error method as one which answers the requirements of practical men, we cannot but feel a sneaking disposition to help forward the system by calculation, and, to this end, reprint here the major portion of a paper which deals at length with the practical aspect of the question. For the report of Mr. N. C. Beck's paper we have to acknowledge our Sydney contemporary "The Australasian Photographic Review."—Eds., B.J.P.]

In exposure the factors which have to be considered are:—

1. Strength of the light.
2. Stop or diaphragm.
3. Degree of enlargement.
4. Focal length of the lens.
5. Speed of the paper.
6. Opacity of the negative.
7. Gradation of the negative.

We can easily allow for the first five factors except when enlarging by artificial light, when it is impossible to allow for the strength of the light.

Gauging the Strength of the Light in Daylight Enlarging.

We can accurately allow for the light by measuring it with an actinometer—that is, a meter in which sensitive paper darkens to a standard tint and the strength of the light is inversely proportional to the time of darkening. Some people may object, that in daylight the light may be altering in intensity, even during exposure; but I have adopted the complete solution suggested by that great photographic benefactor, Mr. Alfred Watkins, of using such an aperture that the correct exposure for the enlargement is identical with the time taken by the paper to darken to the standard tint in the actinometer. So if we hold the actinometer facing the light, illuminating the negative, and uncover the actinometer and the negative at the same time, and then cover the negative when the paper has darkened to the tint, the actinometer will allow for any light variation.

Now, the first thing we have to do is to adopt our standards with which we make our comparisons.

A Standard Negative.

My standard negative is one of medium density or opacity, and of standard contrast; a fairly plucky negative which will give a perfect

range of contrast when printed by contact on bromide paper and developed in an unrestrained developer to the limit of development. Its opacity therefore equals 1.0, one. I will give later on means of comparing the opacities of negatives.

Paper Speed Numbers.

The speed numbers which I have adopted are half those on the Watkins's speed card, because my standard negative is of medium density, while Watkins's is a "decidedly dense" negative, which might be rated as opacity 2.

The following is the table of speeds as I have found them:—

Barnet—Platino matte	12
Empire	3
Kodak—Royal, creme, crayon, and white, platino matte rapid	25
Pearl	3
Wellington—Platino matte	12

I find that these values do not agree with the Watkins numbers, but I have just re-tested them, and find them exactly as given.

Actinometer.

I use the Imperial, or the Watkins's actinometer, for determining the light intensity, as the speeds of the papers are about the same. The Wynne paper I find is of a different speed from the Watkins or Imperial, and so allowance has to be made; the speed of the Imperial paper is very constant, and the colour match quite perfect.

Technique.

1. Place the negative in the enlarging apparatus and focus to the desired size, moving lens and easel as usual.
2. Measure the distance from the surface of the easel to the lens diaphragm with a tape in inches.
3. Divide the speed number of the paper to be used (given in above table) by the estimated density of the negative. Call this A. Opposite this A number in the following table find the corresponding f number:—

A Nos.	f Nos.
100	f64
50	f45
25	f32
12	f22
6	f16
3	f11
1½	f8
¾	f5.6

4. Suppose the A number is 50, then the f number is f45. Now if we used an aperture on the lens which had this value, the correct exposure would be identical with the actinometer time, but the stops marked on the lens have different values, according to the

degree of enlargement. To find the stop marked on the lens, which has this f value, we employ the following equation:—

$$\text{Required stop on lens} = \frac{f \text{ value} \times \text{focal length of lens}}{\text{distance from easel to stop.}}$$

Use this stop on the lens.

5. Close the lens or cover up the negative, then pin up the bromide paper (for this a yellow lens-cap is very useful). Now expose the actinometer outside to the light illuminating the negative, and at the same instant open the lens or uncover the negative, and when the actinometer paper has darkened to the standard tint, close the lens.

If you are using an enlarging camera, after inserting the bromide paper and covering the negative or closing the lens, the camera is carried out into daylight and the negative pointed to the sky (do not let the sun shine on the negative). Now hold the meter, facing the sky (also out of direct sunlight), and expose as before.

Two Practical Examples.

1. Opacity of negative = $\frac{1}{2}$ (a thin negative)
Paper Wellington = 12.

$$\therefore A \text{ no.} = \frac{\text{Paper}}{\text{Neg.}} = \frac{12}{\frac{1}{2}} = 24$$

$\therefore f/\text{no.} = 32$ from table.

Lens, Ross Homocentric, focus, 7 in.

Distance from stop of lens to easel = 21 inches.

$$\therefore \text{stop required} = \frac{f/\text{no.} \times \text{focal length of lens}}{\text{stop to easel}} = \frac{32 \times 7}{21} = f/10.6.$$

Thus use the stop at the lens marked $f/10.6$

2. Opacity of negative = 2

Paper Kodak royal = 25

$$\therefore A \text{ no.} = \frac{25}{2} = 12.5$$

$$\therefore f/\text{no.} = 22$$

Lens, Ross Homocentric, 7 in. focus

Stop to easel = 28 inches

$$\therefore \text{required stop on lens} = \frac{22 \times 7}{28} = f/5.5$$

Now, my lens does not work at $f/5.5$. Hence, I will halve the diameter of the stop, using $f/11$, and let the actinometer darken four times, or if it is a fairly clear day and the light is constant. I give four times the actinometer time. When we use an aperture of half the diameter, we must give four times the exposure; e.g., $f/16$ needs four times the exposure of $f/8$, for the area of the stop varies with the square of the diameter.

Allowing for the Opacity of Negatives.

We will consider the one factor which is difficult to allow for—viz., the opacity of the negative. At the outset the classification of opacities is probably different for enlarging than for contact printing; it is certainly so if there is much fog present.

In contact printing, after the light has passed through the negative, it immediately comes in contact with the sensitive paper which catches it. But in enlarging the conditions are different (see diagram). The light that strikes a part of the negative that has a deposit of silver on it does not pass wholly straight through, but some of it is reflected at an angle by the grains of silver, and does not reach the lens, and is so lost; hence, the light passing through is of less intensity than if all of it went straight on to the lens. On the contrary, in the transparent portion of the negative the light is not interfered with in the slightest. When fog is present, there is much diffusion. Thus we find the optical conditions are quite different.

A negative which gives perfect gradation with an unrestrained developer in contact printing, when using artificial light, is too hard for enlarging by the same light. Messrs. Hurter and Driffield

have estimated that a contact printing density of 0.8 corresponds with an enlarging density of 1.4. We can get over this hardness by using a more active or blue light—viz., daylight. The colour and strength of the light certainly affecting the steepness of gradation in the result. A strong light and a blue light tend to reduce contrasts; a weak one and a yellow light to increase them.

There are, however, two good methods for allowing for the opacity.

First Method.

Select a number of negatives of varying opacity or density, to act as pilot negatives, from very thin negatives of density $\frac{1}{4}$ (say) to dense negatives of density 4; let them be clean, i.e., free from fog. Now, find out from the method below their exact opacities for enlarging. We then take our unknown negative and see visually which pilot negative is nearest to it in density, or between which two negatives it happens to lie, and so find out its opacity very exactly. The more pilot negatives the easier the comparison. It is important that the negatives are perfectly free from stain, or, if stained, equally so. It is better to use a non-staining developer, or to use a properly compounded acid fixing bath.

Second Method.

Focus the image in the enlarging apparatus so that it is the same size as the negative (or smaller, if convenient). Now, use as a trial slip a piece of paper embracing the whole image; you can then gauge your gradations perfectly, and can see the general effect.

This would be impossible with only a portion of the picture. Of course, in arriving at the exposure for the trial slip we gauge the opacity of the negative as closely as we can visually—i.e., compare with the standard negative, and use the foregoing exposure system—most likely it will be very nearly correct in the first exposure. In developing this slip we must develop to the limit, using (say) rodinal with no bromide (rodinal 30 minims, water 1 oz.), or very little bromide. Any developer will do as long as it does not stain and is not restrained. If the resulting print, when viewed by gaslight or subdued daylight after having been fixed, is too dark, we have over-exposed; if it is too light, we have under-exposed. In this way we find out our opacity number, then proceed to enlarge to the desired size.

Technical Details.

There are one or two practical details which call for mention:—

The question may be raised: "How can you get out of the dark-room to hold the actinometer near the negative, to test the light falling on the negative, seeing that you must have your paper pinned up ready for exposure, and having to give the exposure from the outside, you cannot admit light by opening the door?"

1. You may have your dark-room opening into another room, which you can temporarily darken—as I have done.
2. You may get some one else to hold the actinometer outside and make the exposure for you.
3. You might have a little box opening on to the reflector near the camera, with a yellow glass window at the side, through which you might observe the darkening of the meter.
4. You can choose a day which is tolerably clear, and expose about

middle of the day, when the light is constant. Make the cinometer test, timing it with a watch, and go inside and pin up bromide paper, and give this time. Of course, there must be no rapidly moving clouds, with periods of shade and sunshine. 5. You may use an enlarging camera and carry it out and expose as before described.

All this technical explanation sounds very complicated when compared with the trial and error plan, and, indeed, it has taken some time to explain. But it is not so; in fact, it takes much less time, it may take $\frac{1}{2}$ minute to estimate density of negative, $1\frac{1}{2}$ minutes make our calculation; total, 2 minutes. The rest, pinning up, exposing, etc., is the same in both. Now, it takes longer than 2 minutes to expose and develop the trial slip, and then we have the great difficulty of estimating from a small portion of the image whether exposure is right or not. The only thing we must be sure

not to do is to under-expose, remembering that with the following system of development slight over-exposure is of no consequence whatever. Even if we are not aware that we have exposed, we can safely give twice the correct exposure, and even more, and we can be quite sure that our exposure lies somewhere within this limit. It is well to keep a notebook for full data, exposures, magnification, paper, etc.

For those who are content to use a fixed focus enlarging camera, a fixed stop, and one brand of paper, the only factors which have to be considered are the opacity of the negative and the strength of the light, hence the exposure problem is somewhat simplified.

It is well in practice to use only one brand of bromide paper, as you get to know its idiosyncrasies. N. C. BECK.

[The concluding portions of the paper must be held over until our next issue.—Eds. B.J.P.]

PAINTERS AS JUDGES OF PHOTOGRAPHS.

We often see the question raised, "Who is the right person to judge pictorial photographs?" and, of course, this question implies the further one, "Is it better to have a painter's views on art applied to a photograph, or should such judging be confined to photographers only?" A writer in the "County Gentleman," one of our contemporaries which presents each week a well-edited page of photographic notes, discusses the pros and cons of these vexed questions some length.

A Photographer on Technique.

Undoubtedly the photographer is the right man to judge on questions of photographic technique, just as the painter is the right man to consult to find out if a picture is well painted. But in a pictorial photograph something more is aimed at than an exhibition of technical excellence, and this something else this pictorial quality needs to be appreciated at its proper value.

The Dangers of the Painter.

There is one danger inherent in the painter's appreciation of a photograph that I saw well described in an article a short time ago. There are certain effects that are produced by a painter laboriously and carefully—gradation in a sky, for example—that may quite possibly be produced by a lens correctly in a moment. The painter may well over-value a result which to him would have been difficult, whereas to the lens it is easy.

Judgment by Aim.

But I think it is fair to remember that this is, after all, still a question of technique. A painter, in judging pictorial photographs, ought to lay aside altogether all thoughts as to how the picture has been produced, and should simply estimate the pictorial quality of the result before him. It seems to me that such expressions as "faking," "dodging," etc., are often misleading. If the photograph is shown as a specimen of work done by the lens, then, of course, it ought not to be worked upon by hand; but, if it is shown as a picture, it has a right to be estimated as such, without any reference to the means that have been taken to produce the effect. The only question is—Have these means attained their object? A man may use any method he pleases if it produces a beautiful result, but the quality of that result must be determined by minds that are trained in art. At present, at any rate, minds of this character are far more likely to be found amongst painters than anywhere else. In course of time there may emerge men who are accepted as artists, and whose experience has been acquired

through photography, and not through painting; but it is very unlikely that any man will attain such a position without studying the acknowledged masterpieces of art and the accepted principles that guide all artists in their work.

One point of great importance is that a picture of any sort should be judged according to its aim. "How far has the artist realised or fallen short of his intention?" is the point to be examined by the critic, not merely "Has the artist produced a picture which appeals to me?"

In painting, of course, the same question is all important, but the different aims followed by different painters are more widely understood. It is known that the same picture is unlikely to excel in power of design, in harmony of line, in beauty of colour, and in well-balanced light and shade, and there are many different schools of painting that produce widely different results. But in photography the fact that differences of aim exist is not yet so fully recognised. A man who produces work of the older type of excellence, consisting of elaborate detail in the sharpest possible focus, is with difficulty brought to acknowledge that another man's work can have real merit, although expressed in sombre masses, low in tone, and indistinct in outline. All this kind of thing he is apt to consider simply bad work, and to condemn accordingly; whereas, of course, a picture of this broader kind may well have achieved a true pictorial excellence. An artist judging by results alone is more likely to have a balanced mind, from the fact that he is no partisan of any school of technique.

A M \acute{e} tier for Photography.

It is to be hoped that from all the pioneering work now going on there may emerge some definite knowledge as to what type of pictorial work photography is most fitted to produce. There may then be a recognised school, which does not practise a mere imitation of painters' methods, and has got rid of the early affectation which delights in defying all accepted conventions, so that we may realise that pictorial photography has a definite m \acute{e} tier of its own.

At present the pioneers are making vigorous experiments in all directions. Many eccentricities, highly praised but a short time ago, are now seen to have been off the lines of real advance. The chief need is that those things should be studied which find their expression better through the lens than through any other medium. An art founded upon such things as these must be truly characteristic of photography, and would be welcomed, because of its power of expressing itself in a field of work that the recognised arts have not hitherto been able to make their own.

OUT OF THE RUT ADVERTISING.

THE "British Advertiser," which by the way has now established itself in London at Queen's Anne's Chambers, Westminster, publishes in its August number an interview with Messrs. Taylor, Taylor, and Hobson, of Leicester, on their distinctive methods of advertising "Cooke" lenses. The interviewer writes:—"Appreciating the value there is attached to a cross mark against the side of any matter to draw attention to it, Messrs. Taylor put a cross against all their announcements, with the result that they at once stand out. In case others may haste to copy the idea, I give the following bit of conversation I heard only the other day. Another photographic manufacturer, with more appreciation for the value of the idea than originality, is attempting to distinguish his announcements by putting a tick against them. 'See this?' said one camera enthusiast to another, 'that's not a bad idea to draw attention to an advertisement?' 'Oh,' said the other, 'they've copied Taylor, Taylor, and Hobson. They always put a cross against their advertisements.' Then followed a long dissertation on Cooke lenses, which by the way were not being advertised in the paper they were looking at, to the total exclusion of the real advertiser.

"There is a hint in this for those people who are fond of slavishly copying any good idea that comes along. They forget the obvious fact that the idea is associated with the original advertiser, and that in many instances the effect of their copying it will only be to accentuate the original advertisement."

Discussing the opportunities for powerful advertising of lenses, the writer pictures the photographer dissatisfied with his optical equipment for some particular reason.

"Turning over the pages listlessly, he comes across an announcement of the Cooke lenses and he is interested at once. There's a 'reason why' in each of them. In dull weather you are reminded that you can take pictures in a fraction of the time required for other lenses to operate because of the wide aperture of the lens. Perhaps at the moment you are interested in enlarging or copying your attention is drawn to the flat field of the Cooke. Price may be a consideration; you are shown how by its simple construction the Cooke can be sold cheaper than other lenses, and so through all the gamut of reasons that could possibly be adduced to persuade you to become a possessor of a Cooke. Each is dealt with in turn, and in each announcement there is a 'good reason why' you will be acting wisely in acquiring such a lens.

"Messrs. Taylor do not believe, however, in relying on their announcements only. At the foot of all their advertisements is a line 'Send postcard for particulars.' This is usually keyed, and a request for further particulars brings a neatly got up little catalogue as chock full of argument as one could wish. Following this comes a series of follow up letters, each one a little more persistent than the preceding, the last culminating in a request to know the reason why the order has passed them."

We have already reported the threatened demise of the Camera Club as a separate entity, and on the 22nd inst. an extraordinary general meeting of the Camera Club Company will be held to consider, and if it were deemed expedient, to adopt, a formal resolution for winding up of the same. Provisional arrangements have been made with the Club Trust Company, the proprietors of the Blenheim Club, by whom members of the Camera Club can be nominated as members of the Blenheim before November 30. Up to the 1st inst. only 120 out of the 400 town and country members of the Camera Club had signified their intention of being absorbed by the Blenheim. The Camera Club will finally close on the 31st inst.

Photo-Mechanical Notes.

Etching Zinc Plates.

THE effect on the structure of zinc plates by enamelling the image was shown, by photo-micrography, in a previous issue of this Journal. In that case the zinc was fractured to show the change of grain. The writer has often observed the effect on "perished" zinc of the nitric acid etching bath. Before placing in the bath the surfaces of normal and perished zinc

Fig. 1.—Photo-micrograph of normal zinc plate after etching with nitric acid.

have practically the same appearance, but directly the metal is placed in the etching bath the difference of structure is immediately demonstrated.

The normal metal etches with an even, dull surface, whereas the heated zinc shows its crystalline structure directly the acid

Fig. 2.—Photo-micrograph of enamelled zinc plate after etching with nitric acid.

flows over it, and the surface of the metal assumes a coarse granular appearance with bright sparkling specks of metal.

Under the microscope, the surface of the unheated zinc appears of a fine, even grain of a grey tint. The perished zinc shows a large irregular grain. Some of the crystalline granules are of

distinct bluish tint, probably owing to slight impurities in zinc. The effect of the acid on the surface of the two kinds of metal is shown in the accompanying photographs taken with a two-thirds-inch objective. The first illustration shows the small zinc with the comparatively even surface; the second shows the appearance of the perished substance with its crystalline structure developed by the nitric acid. Enamelling does not seem to affect the rapidity of the etching to any appreciable extent. Two-line blocks printed one on perished zinc and the other on normal metal and etched for the same period of time are both of the same depth when removed from the bath.

J. I. Pigg, F.R.P.S.

The Citrate Bichromate Bath for Photolitho Paper.

Professor Namias gives, in the current number of the "Zeitschrift für Reproduktionstechnik," a preliminary note on the above subject, the experiments being based on the much greater stability of carbon sensitive on a bichromate and citric acid bath. If Rives' paper is coated with albumen and bichromate, rendered alkaline with ammonia, a good photolitho transfer paper is obtained, which, however, only keeps for a short time. If, however, 2 to 3 per cent. of citric acid is added, the paper will keep much longer. The actual formula will then be:—

Potassium bichromate	10 gms.
Water	100 ccs.
Liq. ammonia	q.s.
Citric acid	23 gms.

From 10-15 ccs. of this should be added to every 100 ccs. of egg albumen, and the paper floated on the mixture. This paper will keep for three weeks at least, and then give transfers on zinc as good as freshly prepared paper. Details are promised as to the use of citric acid in the bichromated films for collotype.

Shrinkage of Stripped Films.

To a reader of Penrose's "Process Work" who asks for help in stripping a collodion film square and exactly to size, the following reply is given:—

"First, let the film dry—gummed or ungummed does not matter. Wet the edges $\frac{1}{4}$ in. wide all round, and then neatly, with a piece of square wood, remove the wet strip of film, and rub clear of the smallest fragments all round with a cloth, pinching the edge of the plate. 3. Have ready a gelatinised plate. The gelatine is very particular; it must be of fair quality, and should have a mixture of stale or inferior gelatine, otherwise the surface is as biting to the collodion film under water as if it were in the air and you touched it with the finger. We all know the peculiar grip of pure and freshly set gelatine. The same smoothness or freedom from grip under water may be got by a very small mixture of fish-glue. But it is easy to add too much, and the collodion film then refuses to grip when wanted. These gelatinised glasses are preferably dry and in stock; they may also be made by bleaching out dry-plate negatives or spoilt dry plates so as to be clear and transparent. 4. Now bathe the negative in a dish so as just to cover it with water acidulated with hydrochloric acid about 7 per cent. Leave it in awhile and the edges will be seen to rise, and as separation goes on the whole film will presently float. It is often well to take out early and rinse it from the jug, holding the upper edge with the thumb on the glass. Meanwhile, it will become quite free. 5. Place the gelatine glass in a dish about 1 in. deep in water, and on the far edge of it a strip of glass about $\frac{1}{4}$ in. thick. 6. Now turn over the negative with the loosened film face down, and lay it carefully upon the future support with the space produced by the glass strip on the farther side. 7. In a minute or two the film will drop slowly from the upper glass, and

can be assisted by passing the water away from the operator on either side of the glass, when a return current is caused which runs in between the film and the glass, and so it gradually gets clear. 8. When nearly or more than half clear, begin by putting the fingers under the far edge of the upper negative glass, and very slowly and steadily lifting it. As it rises the currents in the water may be caused similarly to keep the floating film straight, and cause it to clear itself from the upper glass, which is deftly and slowly removed, the last part being very careful. 9. The film, now floating freely in the dish, is adjusted by the two thumbs on the far edge, and gradually the lower glass is lifted, keeping it carefully to an angle of 15 deg. until it is lifted right out. Keep it down on the far edge with the thumb, by which it will become attached, and on draining it will be found to settle with practically exact truth, and can be biased a little this way or that by the thumb or finger during the draining, after which it dries in a few minutes. It is usual to lay it on a gentle slope to drain, and a small weight or two along the top will prevent it slipping altogether away. This method has served me many years, and I was never put out with the least distortion."

The Direct Reproduction of Plastic Objects.

The direct reproduction of any solid object in half-tone is generally acknowledged to be much more difficult than a mere print or flat surface, and Herr Mente gives some useful hints on this subject in the "Zeitschrift für Reproduktionstechnik." One of the most important things is the illumination, and this must be arranged for each object, so that brilliancy is avoided as far as possible. If the object has low relief, then the lighting must be from one side; if high relief, on the other hand, the lighting must be "soft" and more from the front. Polished objects are always difficult because of the hard and spotty lights, and these should be obviated by painting with a thin paste of magnesia or chalk. Silver and glass vases and bowls can be "matted" by putting pieces of ice in them, and a great deal of reflection may be avoided by hanging a neutral grey, dull cloth behind the camera. In taking glass vases, particular attention should be paid to the background, so as to avoid extreme contrasts. When a lot of small objects are to be included in one plate, they can be temporarily cemented to a sheet of plate glass, so as to avoid shadows, and a card of the desired colour placed some distance below the glass. As regards the lens, it is usual to employ a focus of from 45 to 60 cm. for plane objects, and such a lens may be also used for small objects, but for large ones a shorter focus will be more convenient, and this introduces the difficulty of the screen distance, which will in certain cases become less than the thickness of the glass, so that limits are thus set to direct work. It must not be forgotten when choosing the stops that not only is it requisite to have the proper shaped dot, but also sufficient depth of focus to get all planes sharp.

The work of students in the Bolt Court School of Photo-engraving, Fleet Street, London, E.C., is given a prominent place in the "Inland Printer" for August, where the separate impressions and the complete trichrome from a set of three-colour blocks made by students are presented as a series of supplements.

Who said American invasion? We now read in the "Inland Printer" that the firm of Penrose and Co. is establishing in New York a house for the supply of all process apparatus and materials, and will carry on in America a business such as that which it has so successfully established in Great Britain and the Colonies. The announcement comes as a natural sequel to Mr. William Gamble's recent visit to the States, and we congratulate the management at 109, Farringdon Road, on the enterprise which now bids fair to make their house world-famed in the process-materials trade.

Exhibition.

ANDOVER.

The fifth amateur photographic exhibition held in connection with the Andover and District Horticultural Society was opened on Monday last. The exhibition is a great advance on previous shows, all classes being well supported. The judges, Messrs. F. J. Mortimer, F.R.P.S., and W. Milman, M.A., made the following awards:—

OPEN CLASSES.

Class A. (Portrait and Figure Studies):—Gold medal, Miss B. Stanford; silver medal, A. W. Walburn; bronze medal, Rev. E. G. Watts; certificate, C. Castle Sloan.

Class B. (Landscape and Seascape):—Silver medal, Fred Judge; bronze medal, Rev. E. G. Watts; certificate, M. Willis; extra certificate, G. Vials.

Class C. (Architecture):—Silver medal, W. G. Hill; bronze medal, Alfred Roffey; certificate, James Dunlop.

Class D. (Postcards):—First prize, J. H. Saunders; second prize, A. H. Almond.

CLASSES OPEN TO ALL AMATEURS RESIDING WITHIN A RADIUS OF TWENTY MILES OF ANDOVER.

Class E. (Landscape and Seascape):—First prize, Miss M. Best; second prize, Rev. E. G. Watts; third, T. C. Baynon.

Class F. (Architecture):—Rev. E. G. Watts.

Class G. (Figure Studies, etc.):—First prize, Rev. E. G. Watts; second prize, T. C. Baynon.

Class H. (Novices):—First prize, H. C. Wood; second prize, George Knowles; third prize, Mrs. Barr.

FORTHCOMING EXHIBITIONS.

July 4 to August 12.—Northern Photographic Exhibition. Secretary, F. G. Issott, 62, Compton Road, Harehills, Leeds.

August 24 to September 21.—Berwick-upon-Tweed Arts Club. Hon. Secretary Pictorial Photography Section, H. Hancocks, 38, Ravensdowne, Berwick-upon-Tweed.

September 8.—International Exhibition at Budapest. Address, Secretary of the Photo-Club, Egyetem-ter 5, Budapest, IV.

September 15-October 21.—Photographic Salon, 5a, Pall Mall East. Hon. Secretary, Reginald Craigie, Camera Club, Charing Cross Road, W.C.

September 21-October 28.—Royal Photographic Society, New Gallery, 121, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

October 17-18-19.—Isle of Wight Photographic Society. Hon. Sec., V. Howard Burgess, 53, Pyle Street, Newport, I. of W.

October 18-21. Rotherham Photographic Society. Hon. Secretary, H. C. Hemmingway, Tooker Road, Rotherham.

October 19-21.—Grangemouth Amateur Photographic Association. Hon. Secretary, Robert Marshall, 3, Park Terrace, Grangemouth.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

November.—Edinburgh University C.C. Hon. Secretary, Harold C. Simpson, University Union, Edinburgh.

November.—Bristol and Clifton Arts and Crafts Society. Secretary, R. H. Parr, 5, Grove Buildings, Blackboy Hill, Bristol.

November, December, January.—Second American Photographic Salon. H. Snowden Ward, 6, Farringdon Avenue, London, E.C.; Wm. T. Knox, 279, Washington Street, New York City, U.S.A.

November 3, 4, 5.—Motherwell Young Men's Institute C.C. Hon. Secretaries, James Dunlop, Myrtlebank, Motherwell, and Archibald Matthews, 24, Enfield Place, Ladywell, Motherwell.

November 8-15.—Croydon Camera Club. Hon. Sec., W. H. Rogers, 88, Woodville Road, Thornton Heath.

November 14, 15, 16.—Ipswich Camera Club. Hon. Sec., R. H. Sutton, 37, Henley Road, Ipswich.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

November 25-December 2.—Glasgow Eastern A.Ph.A. Hon. Secretaries, Thomas B. Kirkhope, 37, Winston Street, Parkhead, Glasgow, and John Brough, 68, Dalmarnock Street, Parkhead, Glasgow.

December.—Muirkirk A.Ph.A. Hon. Secretary, William Barrowman, Ayr View, Muirkirk.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 6-7.—Watford Camera Club. Hon. Secretary, E. H. Jackson, 100, High Street, Watford.

December 12.—The Scottish Photographic Federation Lantern Slide Competition. Entries to Hon. Secretary, John B. MacLachlan, Mairgowrie.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

December-January.—Wishaw Ph.A. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January, 1906.—Shettleston Camera Club. Hon. Secretary, Win. Kitson, Hawthorne Villa, Shettleston.

January 13-February 3, 1906.—The Third Scottish National Salon at Dundee. Hon. Secretary, V. C. Baird, Broughty Ferry. Entries close December 30, 1905.

February 13-27, 1906.—Greenock C.C. Hon. Secretary, W. D. Boyd, 2, Church Place, Greenock.

March, 1906.—Larkhall C.C. Hon. Secretary, Robert Rodger, 26, M'Neill Street, Larkhall.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern P.A. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 19-24, 1906. Sunderland Photographic Association. Hon. Sec., William E. Kieffer, Stirling Street, Sunderland.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 1, 1906.—Coatbridge Co.-Op. C.C. Hon. Secretary, James Robb, 6, Windsor Terrace, Blenheim, Coatbridge.

FORTHCOMING COMPETITIONS.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 in prizes for photographs taken with Thornton-Pickard cameras or shutters.

October 15.—Lantern Slide Competition, Association Belge de Photographie. Secretary, Palais du Midi, Brussels.

October 31.—"Zigo." Cash prizes for prints on "Zigo" self-toning paper. Thos. Illingworth and Co., Limited, Willesden Junction, London, N.W.

November 30.—Royal Photographic Society "Affiliation" Print Competition. Particulars from the Secretary, 66, Russell Square, W.C.

December 30.—Royal Photographic Society "Affiliation" Lecture Competition: (a) Illustrated lecture descriptive of a tour; (b) Illus-

ted technical lecture. Particulars from the Secretary R.P.S., 66, Finsbury Square, London, W.C.

February 6-9, 1906.—Guisbrough Fine Art and Industrial Society, Photographic Section. Hon. Sec., G. H. Angus, 34, Westgate, Guisbrough.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes.

The following applications for patents were made between July 29, 1905:—

LOUR PHOTOGRAPHY.—No. 15,185. "Improvements in multi-colour photography." Charles Louis Adrien Brasseur, 18, Southampton Buildings, Chancery Lane, London.

ULSIONS.—No. 15,214. "Improvements in the manufacture and production of emulsions and other materials sensitive to light." James Harris, Paul Gillard, and Henry Hearn Molyneux, 2, Beaufort Villas, Sandycroft Road, Kew Gardens.

VELOPMENT APPARATUS.—No. 15,262. "An automatically rocking developing apparatus for photographic plates, films, and the like." George Beston, 306, High Holborn, London.

FOUSSING.—No. 15,341. "Focussing device for magazine cameras." John Herbert Briggs, 36, Bridge Street, Castleford, Yorks.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

MONOCROMA CAMERAS.—No. 19,427, 1904. The patent relates to a camera with a lens swinging on an axis which passes through the optical centre of the lens, and provides for the employment of film of less length than the longest the camera will take. There are also:—Improved means for regulating or adjusting the speed of the swinging lens-carrier and thereby timing the exposure; and arrangement of the body of the camera in such a manner that the internal parts are rendered easily accessible and the introduction and removal of the films facilitated. The numerous diagrams are necessary to explain the construction. John Boulton Brooks, Finstall Park, Bromsgrove, Birmingham.

THREE-COLOUR CAMERA.—No. 4,290, 1905. The patent is for a camera with a particular arrangement of screens and reflectors for simultaneously taking all three negatives, viz., as follows:—The blue-sensitive plate is placed where it receives the image from the second reflector, the green-sensitive plate where it receives the image at first reflection, and the red image is received direct. The arrangement permits of the quickest exposures consistent with the requirements of the red plate and more correct adjustment of the quantity of light allowed to act on each plate so as to secure more truthful rendering of the colours of nature. By placing the green in the position opposite the first reflector it gets the strongest reflected light and the red at the back is not needlessly kept back. The drawing shows a section of a camera with the two reflectors a. b. c. d. e. are the three plates, and f. g. coloured screens before the first two plates. The first reflector (a) transmits red, orange, yellow and blue, and may be called a "pink reflector," though it may appear to the eye heliotrope, mauve or magenta. The second reflector (b) transmits red, orange and yellow, and may be called "yellow," it may appear to the eye red or orange. A

portion of the light passing through the lens is reflected from the reflecting surface of the reflector (a) passing to the plate (c). This light is filtered of all rays except the green and a portion of the yellow, by the green screen (f). A portion of the red, orange, yellow and blue rays which have passed through the reflector (a) is reflected by the second reflector to the plate (d). These rays are again filtered of all but the blue rays, which are to act on the blue taking plate by a blue screen (g). This screen should be so coloured as to exclude the more active violet and ultra-violet rays which will prevent plate (d) from being over-exposed compared to plates (c and e), the violet colours of the subject being reproduced in the photograph by combinations of blue and red. The red, orange and yellow rays pass through the second reflector on to the red plate (e) situated at the end

of the camera. In place of the reflectors being parallel to each other, as shown, they may be at right angles to each other, in which case plate (d) will be on the opposite side of the camera to that on which plate (c) is situated. Should it be desired to make the colour records to consist of suitably adjusted secondary colours instead of primary colour sensations, this arrangement will still hold good—the slow colours being assigned to the position of the greatest illumination and the quickest to the position of least illumination. It is not necessary to have the reflectors movable for the purpose of adjusting their position as the correct position of the faces of the reflecting surfaces can be ascertained once for all by calculation or experiment, having regard to the thickness of the glasses used in the reflectors and screens. It is only necessary to adjust the lens to the distance from the subject, that is, to focus the subject as in ordinary cameras for one plate, and when one plate is in focus the others will be also. Edwin Tranter Butler, 26, Craven Park, Willesden, Middlesex.

MULTIPLE PICTURES.—No. 7,900, 1905. 1. A photographic apparatus in which a number of separate subjects or views may be taken on a single plate, by means of one lens mounted on two screens, one being adjustable vertically and the other horizontally, the camera being also provided with a removable compartmented partition. Abbé Antoine Cardon, Castel Lorrain, Beausoleil, Monaco (A. J. Boulton, 111, Hatton Garden, E.C.).

DRAINING RACK.—No. 8,964, 1905. The patent is for the combination in a photographic draining rack (of the folding type, in which grooved rails, or boards, for supporting the negatives are fixed to pivoted X legs which open at right angles) of rails made V shape in section, and of metal legs furnished with right angle flanges for the purpose of forming direct resisting stop abutments to prevent the legs from spreading when in use, and

for providing a convenient means of attaching the rails. Houghtons, Ltd., 88-89, High Holborn, London, W.C., and Herbert Holmes, Tudor Works, Tudor Road, Hackney, London.

MULTI-FILM ORTHO PLATES.—No. 9,246, 1905. The claim is for a double or multiple film of isochromatic emulsions, one of a different character from the other. The slower emulsion having been applied as a first layer on a support (which may be temporary or permanent according as a flexible photographic film or rigid plate is required) and dried, the faster emulsion (made in the same manner but differing from the first in its higher degree of sensitiveness to the actinic rays) is then applied as a second coating on top of the first or slower coating and allowed to dry, and so on for as many superimposed coatings of progressively increasing degrees of sensitiveness as may be deemed necessary to ensure the complete interception of the rays. The film may then be stripped off the support and used as a flexible film, or it may be left on the support and used as a plate. There are a number of aniline dyes which may be used for the first or slower emulsion (for examples, dyes of the erythrosine series), while for the top or faster emulsion a mixture of the dyes of this series with a yellow dye (for example, nitrophenine or other dye of that nature) may be employed. The emulsions are of the ordinary silver bromo-iodide formulae. The dyes in liquid form are added to the emulsion, which is prepared in the usual manner previous to coating the support. The advantages obtained by this invention as compared with the ordinary single layer of isochromatic emulsion is the absence of all halation and false tone-rendering due to imperfect interception of light rays, and the wider and more perfect tone-rendering due to the colour sensitiveness of each layer of emulsion of which the film of this invention is composed. Sandell Films and Plates, Ltd, 213, Selhurst Road, South Norwood, London, S.E., and Leonard Smith, 22, Park Hill Road, Croydon, Surrey.

New Apparatus, &c.

The "Brownie" Stereo-Printing Frame. Made by Kodak, Ltd., Clerkenwell Road, London, E.C.

With this compact printing frame negatives on glass or film can be printed on to a single piece of paper, and when finished can be mounted for the stereoscope without transposition. In use the frame

is very simple and rapid, and is strongly, yet lightly made. The prints are obtained with a narrow white margin, and with the pictures level and at the right distance apart, we conceive that users of the Brownie stereos will find the frame an indispensable adjunct to their outfit.

THE V.H. WASHER. An improved pattern of this washer has been submitted to us by Houghtons, Ltd., of 88 and 89, High Holborn,

W.C. We have already reviewed the apparatus, and can speak well of its capabilities. It is well and strongly made in enamelled iron. The direction of the jet entering the washer is so arranged that circular motion is set up, and this motion is continued by the impetus of the inrushing water. The prints, therefore, are kept continually on the move, and as there is no vortex they do not all clog together in the centre. This vortex, which is the usual failing of circular washers, is prevented by a central column or core, which gives an even circulating motion to the moving water, and prevents the prints sticking together. The movable bottom is perforated in a helical manner, so that hypo or other foreign matter is quickly carried off, drained away by means of a central conduit. The V. H. is also fitted for plate washing, and does this as effectively as it washes prints. The price of this washer is now 6s. for 12 inches in diameter, 13s. 6d. for 17 inches, and 21s. for 22 inches. This last size is large enough to wash prints up to 12 x 10 size. The V.H. is supplied either as a print and film washer only, or as a combined print and plate washer, the latter being slightly more expensive, but in any case they cannot be considered dear, and are very good value for the money.

New Materials.

Ensign "Slip-in" Postcards. Supplied by Houghtons, Ltd., 88-89, High Holborn, London, W.C.

The fecundity of the picture postcard goes without saying in these days, and we cannot be astonished by any introduction which adds a novelty to what seemed infinite variety. Messrs. Houghtons, Ltd., at one fell swoop have caused the photographic postcard to multiply in the earth, the swoop being in the nature of a slip-in mount, postcard in size and shape, but with openings for prints quarter-

plate or less in size. Thus the small print that would otherwise be thrown away becomes a postcard, though in justice to prospective senders of the cards, it must be pointed out that officially they are not postcards, but letters or book packets, according as a message is or is not written upon them. Messrs. Houghton do not say so, but we imagine that when bearing only the sender's name and address the "Ensign" card will pass through the post for a halfpenny.

"Chess" Brand P.O.P. Made by Photographic Materials, Ltd., Rickmansworth, Herts.

Samples of a new brand of P.O.P. have been sent us, and although there are a good many papers already on the market, we are always ready to welcome another, provided it can substantiate its claims to popularity. "Chess" Brand P.O.P., however, makes its appearance with no beat of drum or flourish of trumpets, neither does it claim to be the best ever made. By following the directions, how-

ver, the user of this paper will soon discover for himself that it is first-class article. It prints quickly, tones easily, and gives a good colour print. The toning bath recommended is composed as follows:—Ammonium sulphocyanide, 20 grs.; water, 18 ozs.; chloride of gold, 2 grs. When the desired tone has been obtained, the prints are fixed in:—Hypo., 3 ozs.; water, 20 ozs.; and then washed and dried. In hot weather the prints should be transferred to a solution of alum, 3 ozs.; salt, 1 oz.; water, 40 ozs., for five minutes after fixing and rinsing. A glazed surface is obtained on Chess' P.O.P. by squeezing the prints as soon as they are taken from the last washing water, face downwards on ferrotype plate, the surface of which has been previously polished with waxing solution, made as follows:—Spermaceti wax, 30 grs.; benzene, 5 ozs. The paper is sold at the usual rates, and in the usual cut sizes.

A memorandum from the Kodak Company calls attention to the fact that the recently introduced Tank Developing Machine permits of the simultaneous development of any number of films. As the films require but little attention during development use can be made of duplicating outfits which are supplied consisting each of an extra tank, reel, and apron. While one film is being developed a second is rolled up within the duplicate apron in the box, and inserted in the second tank. Duplicating outfits are sold at 6s. to 2s. 6d., according to size.

URBANORA IN THE CAUCASUS.—The expedition which in the early part of the year Mr. Charles Urban despatched to the Western Caucasus has returned to London with records in "animated photography" of several months' travel in Albania, Roumania, Montenegro, Servia, and other countries.

OPEN classes and cash prizes for photography are announced in the schedule of the forthcoming exhibition of the Guisbrough Fine Art and Industrial Society, to be held on February 6 to 9, 1906. The hon. sec. is Mr. G. H. Angus, who will supply all information on application to 34, Westgate, Guisbrough.

On August 3rd, Wm. Scott, photographer's canvasser, of Chapel Street, Swinton, aged 63 years, died under somewhat singular circumstances. The deceased was found asleep in Station Road, Mexborough, and on being brought home a bottle of laudanum was found in his pocket. He regained consciousness once or twice, but finally expired. A verdict of death from natural causes was returned.

An instance of rapid photographic work was accomplished last week by Mr. J. H. Coath, F.R.P.S., of Fore Street, Liskeard, on the occasion of the opening of a new Cattle Market in the same town. Mr. Coath first "snapped" the Mayoral procession, headed by the Volunteer Band, just on the point of entering the market. The next picture shows the Mayor in the act of speaking when declaring the market open, while the third photograph depicts his Worship on the point of unlocking the gate, completing the ceremony, after which the company proceeded to luncheon. Mr. Coath subsequently photographed different views in the market, illustrating in a remarkably life-like manner the animals within the various pens. The negatives were then developed, prints made, then washed, and dried, and sent to the market for the inspection of the company during luncheon, where their appearance evoked much favourable comment. Much interest, too, was shown among the worthy farmers present, whilst "spotting" each other in prints, or recognising either their sheep or bullocks in the pens. Only one camera—a whole plate—was used for the whole of the series. All the various processes were gone through under an hour, Mr. Coath's only assistant being his son.

News and Notes.

DR D'ARCY POWER, for many years a practitioner of pinhole photography, is the writer of No. 70 of "The Photo-Miniature," in which the subject is taken to a more advanced stage than that reached in the earlier number (27) of the same series. Dr. Power is directly practical, and illustrates most of his points. This number of "The Photo-Miniature" brings the appearance of the magazine up to date by the heroic method of omitting the issues from January to June. Subscriptions are advanced, and Editor John A. Tennant holds out the promise of hereafter producing "on time."

THE ROTARY CLUB HOUSE.—We can now give a view of the club house opened at Yiewsley on July 29th in connection with the works and London office of the Rotary Photographic Company, Ltd.

The Social Club of the Rotary Photographic Co., Ltd.

The premises, as we have already said, are fitted up for the entertainment and enjoyment of the employees at West Drayton and Moorfields, and the opening of the house should mark a distinct step forward in the prosperity of the company.

CONSTANT change, as a law of nature, is in no way opposed in Cecil Court, or, more precisely, at Nos. 22 to 27, where Messrs. Gaumont and Co., cinematographers, work without ceasing to produce new subjects almost daily. The latest "Elge" list of films describes the most recent notable additions.

PROCESS and Printing via the Photographer.—Our note of last week is endorsed by Hood and Co., Middlesbrough, themselves specialists in blocks, and also of completely printed circulars, souvenirs, catalogues, &c. A selection of these reaches us, with the reminder to the photographer that it is quite as much or more within his province and to his profit that he should supply and arrange for the finished engravings, and even the illustrated printed matter from the photographs which he has prepared, than an outsider who is not so much concerned nor can have the same personal enthusiasm as the man with the camera. Messrs. Hood show us a number of postcards and pictures for framing produced by their four-colour process, and by a special method of their own designated "Poynter full-tone process." The latter method gives a most pleasing and rich effect, producible with matt or semi-glossy surface, and giving a handsome, and, we think, saleable description of card. We must signalise several very neat photographers' booklets among the specimens.

THINGS were pursuing the even tenour of their way in New York

last week. On M. Witte driving across Brooklyn Bridge and taking the train to Oyster Bay, his way was persistently blocked by the Press photographers, who had to be dispersed by the police.

TANK development is receiving a good deal of attention in America from both professional and amateurs. Several prominent photographers have recently assured us of their desire to possess a reliable and effective system of this kind for development, and we see "The Photo-Miniature" hopes to publish a monograph on the subject in the course of the year.

ON BEING PHOTOGRAPHED.—In an American publication intended for the reading of the public we find a few "Don't's" for the woman who would have a successful photograph of herself:—Don't wear a new and uncomfortable gown. Don't arrange your hair in a new way for the first time. Don't forget white is safest for brunettes. Don't forget black is safest for blondes. Don't forget black lace is always effective with silver locks. Don't wear any stiff neck-dressing. Don't risk decolleté unless your neck is plump. Don't close your lips tightly.

ALUMINIUM PAPER is now employed for various purposes in Germany in place of tinfoil, but a kind of parchment paper coated with aluminium dust by means of a spirit varnish, the whole being subjected to pressure between rollers to cause the aluminium to adhere well. The metallic coating is not affected by fatty matters or atmospheric influences, and as the aluminium paper is cheaper than tin foil it is being substituted for the latter in wrapping up various food products and other articles.

An electrical exhibition is open at Olympia, London, W., on September 25, at which, amongst a large number of other appliances, electric lamps for photography will be a feature. The organisation of the exhibition is in the hands of a committee having its headquarters at Balfour House, Finsbury Pavement, E.C.

THE NORTHERN EXHIBITION.—The fourth visitor entitled to select a picture from the walls passed the turnstiles on July 30, in the person of Mr. W. H. Hodgson, who chose a photograph by J. E. Latham, entitled "On Lago Maggiore." This idea of our Leeds friends appears to have worked excellently in practice, and the scheme of awarding a prize to every thousandth visitor is one which other societies may note as offering possibilities for local advertisement.

THE Shah of Persia was busy with a Kodak during his visit to Paris last week. Early in the forenoon he was in the Bois. There he arranged his suite and the municipal guards who form his escort Persian-wise—that is, tailor-wise—on the greensward of the Pré Catalan, and took several photographs. Then, espying a group of ladies, among whom was Mrs. George de Reuter, wife of the London representative of the Bank of Persia, the Shah photographed them, also, and then went back to lunch.

DEATH OF MRS. MAWSON.—On Wednesday in last week, at Alnmouth, the death of Mrs. Mawson, widow of the late Mr. John Mawson, founder of the firm of Mawson and Swan, took place. Mrs. Mawson had reached the great age of 82 years, and her death is a reminder of the tragic circumstances under which her husband met his end in 1867. A large quantity of nitro-glycerine exploded, and eight persons were killed, including Mr. Mawson, then Sheriff of Newcastle. Mrs. Mawson, who survived her husband's death by 38 years, was the eldest in a family of eight. One of her brothers is Sir Joseph Wilson Swan, the eminent electrician, another is Mr. John Cameron Swan, and a sister is the wife of Mr. John Pattinson, the Newcastle City Analyst. Mrs. Mawson is survived by three daughters and one step-daughter.

Commercial & Legal Intelligence

PHOTOGRAPHIC Obstruction.—The latest form of obstruction Blackpool (according to a newspaper report) is that caused by the taking of photographs. In nearly every street visitors are to be seen grouped in gardens having their photographs taken, and the photographers fix their apparatus either in the middle of the street or on the footpath, thereby impeding traffic. Last week at the police-court four persons were fined for causing an obstruction in this way.

At the North London Police Court last week the case of John Samuel Francis, reported in our last issue, came on again. The prisoner was charged, on remand, with obtaining 2s. 6d. by false pretences from John William Gray, photographer, of Union Square, Islington. It was alleged that the prisoner had taken in bogus orders and thus obtained commission. Several of the orders were produced in court; and one witness was called who denied any knowledge of the prisoner, and also that anybody of the name entered on the order had resided in her house for the past 15 years. The prisoner then said that if he had entered wrong addresses it was owing to his negligence and not to deliberate falsification. He also declared that the prosecutor owed him over £1 for commission, which was more than an answer to the three half-crowns which he had received. The prosecutor denied that he owed the prisoner anything. The prisoner called a witness who said he had canvassed for Mr. Gray, who was not always prompt in his payments. He added that he considered the prosecutor owed him 10s. This also the prosecutor denied. The prisoner asked this witness if he remembered being with him in the "Mother Redcap" on the 17th July, when he got two of the orders which were now in dispute. The witness: Yes; you got into conversation with some women, and two of them gave you orders. The prisoner declined to plead guilty to obtaining money by false pretences, and was committed for trial at the Sessions. He was allowed out on £10 bail.

IMPROPER PHOTOGRAPHS.—At the Clerkenwell Sessions on August 2nd, before Mr. Loveland-Loveland, K.C., two Frenchmen, named Eugene Wegel, 25, bookseller, and Albert Bourlasse, 20, clerk, pleaded guilty to having unlawfully dealt with certain French books, postcards, photographs, and pictures of an improper character. Wegel was ordered six and Bourlasse four months' imprisonment in the second division.

At the London Bankruptcy Court on Friday last the public examination took place of Adolph B. Neilson, photographer, lately carrying on business at 7 and 9, Regent Street, under the style of the International Art Company. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £974 13s. 7d., of which £964 13s. 7d. was expected to rank against the estate for dividend. It appeared that in 1897 the debtor joined a Mr. Thompson in partnership, under the style of the International Art Company. They first took premises at 28, Cockspur Street, but afterwards removed to 20, Regent Street, W. No deed of partnership was executed, but it was verbally agreed that the debtor should work the business, and Mr. Thompson finance it. The debtor put about £500 into the business altogether, and Mr. Thompson put about £2,000 into the business. After trading at 20, Regent Street for some time, they removed to more commodious premises at 7 and 9, Regent Street, W., where they carried on business until February, 1904. The business was very successful and they made a profit. About June, 1902, Mr. Thompson thought it would be advantageous if they went into the wholesale fine art business, and worked it in conjunction with the retail business in Regent Street. They took manufacturing premises at Newman Yard, Newman

street, W., but the venture proved a failure, and brought about the bankruptcy. The examination was ordered to be closed.

PHOTOGRAPHER'S ALLEGED THEFT.—Frederick William Brown, 45, described as a photographer, of 116, Latham Road, East Ham, was charged at Stratford on a warrant for stealing £85, money belonging to his wife, Margaret Ann Brown, on June 8th. Detective-sergeant Anstone said that at 8.30 that (Friday) morning he went to 116, Latham Road, where he saw the prisoner and told him that he held a warrant for his arrest. The warrant was read to him, and then he said, "I didn't steal it, she signed the cheque," but afterwards he added, "I am very sorry. I did have the money, and will pay her back again." Three months.

The public examination of W. H. Hayward, photographer and picture-frame maker, 60 and 61, Long Lane, Smithfield, E.C., was held at the London Bankruptcy Court on Thursday in last week. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £9,993 10s., of which £5,360 8s. 1d. was due to unsecured creditors. The assets consisted of stock-in-trade, cost £7,800, estimated to produce £4,050; trade fixtures, £150; book debts, £2,290; and other items brought up the total assets to £6,563 5s. 7d., from which £279 4s. 3d. had to be deducted for the claims of preferential creditors payable in full, leaving the net assets at £6,284 1s. 4d. It appeared that the debtor commenced business in 1886, without capital, at Paternoster Square, E.C. Three years afterwards he removed to Giltspur Street, and remained there until 1904, when he went to his present place of business at 60 and 61, Long Lane, West Smithfield, E.C. For the last seven years he had also premises at 55, Farringdon Road, and branch shops at Lewisham High Road, and other places in the S.E. district of London. In 1900, he entered into partnership with a Mr. Ellis in a photographic publishing business at Streatham. Eventually disputes arose between debtor and his partner, which resulted in Chancery proceedings, which were settled in his partner's favour, and he was awarded £1,112 and costs. He alleged his failure to have been caused through the action of his partner in the business at Streatham. He had kept the usual books of account, and proper books had also been kept in respect of the Streatham business, but they were in the hands of his partner. When he said he had lost £2,000 in the Streatham business, he included the amount he had spent in law costs in the Chancery proceedings. Replying to Mr. Brinsley Harper, who appeared for Mr. Ellis, the debtor's late partner, debtor stated that he did not keep the books of account relating to the partnership business. He had sometimes sent out partnership goods in his own name. He had not paid all the partnership money into his own banking account. He had never disregarded Mr. Ellis as a partner, and carried on the business in his own name. He had only used his own name in some instances, in order to facilitate business. The partnership business was carried on under the style of Ellis and Hayward. He could not say whether he was solvent or not, it would depend upon the realisation of his estate. After debtor had been questioned at considerable length with regard to certain of the figures in his statement of affairs, and having replied to a few questions put by a barrister who appeared on his behalf, the examination was ordered to be closed.

An international lantern slide competition is announced by the Association Belge de Photographie. There are no classes, and two silver gilt and one bronze medal are placed at the disposal of the judges. An entry will consist of six slides, which must be of regulation size, and they will be judged by arc-light. October 15, 1905, is the latest date for receiving entries, and they must be addressed to the Secretary of the Association Belge de Photographie, Palais du Midi, Brussels, Belgium.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
13.....	Glasgow Southern Ph. Assn. ..	Outing to Luss, Loch Lomond.
12.....	Manchester Amat. Photo. Soc.	Rambles to Middlewood.
12.....	Bowes Park and Dis. Ph. Soc...	Outing to Chingford Marshes.
14.....	Southampton Camera Club	Demonstrations. 1. "Sulphide of Silver." Mr. G. Vials. 2. "Simple Photo-Micrography." Mr. C. M. Cooper. 3. "Combination Printing." Mr. G. Daw.
16.....	North Middlesex Photo. Soc.	"Modifying Transparencies for Enlarged Negatives." Mr. Louis Dick. "Our Library." Mr. A. E. Smith.
19.....	Woolwich Photographic Soc....	Excursion to Slades Green.

THE July meeting of the Torbay Camera Society was held at Park View, Bovey Tracey, the moorland residence of Mrs. Marillier, who invited the members, whilst the August meeting took place at Maidencombe House, by invitation of the president, Colonel W. Fothergill Macmullen. In both instances there were representative gatherings, and after the transaction of the ordinary business, many matters were discussed and experiences interchanged; always beneficial to the tyro as well as the more experienced in the art. Some delightful prints were shown of Ely Cathedral, both of interior and exterior. At the conclusion of the meetings the members were entertained, respectively, by Mrs. and Miss Marillier, and Colonel and Mrs. Macmullen.

Correspondence.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* * We do not undertake responsibility for the opinions expressed by our correspondents.

BACKGROUNDS.

To the Editors.

Gentlemen,—The letter to a "Professional Photographer," in this week's *Journal*, is instructive, and should prove helpful to many, but the assertion is rather wide that there are no backgrounds of the class advocated painted in England. I am now painting dark, unobtrusive interiors (true to different periods), and heavy foliage effects, with breadth and depth, as well as light, simple pictorial ones, which are always useful for children. It is true, however, that the better photographers only go in for the first-mentioned, the middle and cheaper class being largely influenced, on the one hand, by the demands of their ignorant sitters, who desire what they have so long seen that they deem it orthodox; and on the other by the fact that the showy, sharper grounds are more easily and quickly painted by inexperienced painters, and therefore cheaper. It is quite time, though, in the interests of common sense that the arrangements of blossoming curtains and the half Louis, half anything else style, with ferneries stowed half behind all the available ornamentation, should give place to something quiet, simple, and in better taste.

I enclose a few rough prints, and beg to remain, gentlemen, yours truly,

Longford, near Sevenoaks, Kent,

Aug. 4, 1905.

J. EVERETT WILSON.

[Several of the prints sent by Mr. Wilson represent backgrounds done in a reserved, unobtrusive style.—Eds., B.J.P.]

ORTHOCHROMATIC RATIOS OF PLATES.

To the Editors.

Gentlemen,—I am sorry my letter was not as explicit as appears to have been necessary, for I do not think you have yet fully appreciated my point.

Suppose we have an ideally chromatic plate and wish to photograph an object consisting of patches of various colours and tints which are all of equal visual luminosity (though of varying colour), we should expect this plate to give a negative in which all the colours and tints were rendered by equal opacities.

Of such a plate we shall unquestionably say that its ratio

$$\frac{\text{blue sensitiveness}}{\text{yellow sensitiveness}}$$

was represented by $\frac{1}{2}$.

Now suppose we take such a plate and test it in the way Mr. Mees does, we shall not obtain the value $\frac{1}{2}$ for its

$$\frac{\text{blue sensitiveness}}{\text{yellow sensitiveness}}$$

for his yellow light is many times (I do not know exactly how many) more brilliant than the blue, and we should get a factor something like $\frac{1}{4}$ or $\frac{1}{5}$.

I am not quarrelling in the least with the method of testing, but I consider to give the figures so obtained as representing

$$\frac{\text{blue sensitiveness}}{\text{yellow sensitiveness}}$$

is misleading, to say the least.

The last paragraph but one of your article on p. 603, I absolutely fail to understand. To quote your words: "To obtain equal brilliancy we must . . . and having done this we shall have to correct the results by a complicated calculation to bring the factors obtained into line with the conditions of practical work." Suppose, again, we have an ideal plate and test it behind screens that have been reduced to equal visual luminosity, we should, you must admit, obtain a ratio of $\frac{1}{2}$ for its

$$\frac{\text{blue sensitiveness}}{\text{yellow sensitiveness}}$$

and is not this exactly what the practical man requires? For he then knows that photographing objects of blue and yellow colours he would obtain negatives in which the opacity was proportional to the luminosity throughout; or, supposing a plate, tested in the way I suggest, showed a ratio $\frac{1}{2}$ the practical man at once knows that he has to make a screen which only allows 1-3 of the blue to pass. but all the yellow, in order to obtain a correct rendering in monochrome of these colours, when he uses this plate in his camera. I do not see any complicated calculations in this.

But the ratio as determined by Mees' method for an ideal plate would, let us say, be something like $\frac{1}{4}$, which ratio will have no value for the practical man, unless he knew that the relative luminosities of the blue and yellow lights, as used by Mr. Mees, were as 1 to 6. Further, Mees' ratio for the second of the two plates, discussed above, would be $\frac{1}{2}$ or $\frac{1}{4}$; would not the practical man either think he had got a plate which was twice as sensitive to yellow as it was to blue, and would, therefore, require a compensating filter, which actually cut down the yellow, or if he realised that this was not the case, he would be no wiser off, unless he knew the relative luminosities of the light transmitted by the two filters used.

Again, quoting, "Whereas now, knowing the ratio

$$\frac{\text{blue sensitiveness}}{\text{yellow sensitiveness}}$$

any practical worker who also knows the ratio

$$\frac{\text{visual luminosity}}{\text{photographic luminosity}}$$

can at once adjust a colour filter to give his ideal negative." Sur the ratio of

$$\frac{\text{visual luminosity}}{\text{photo luminosity}}$$

with colour sensitive plates is one that must vary according to colour sensitiveness of the plates used, and would require as much determining for every make of plate as the chromatic ratio.

What I contend is that a ratio

$$\frac{\text{blue sensitiveness}}{\text{yellow sensitiveness}}$$

naturally means the relative sensitiveness of the plate to blue and yellow lights of approximately equal luminosity (a good average determination by several people of the colour luminosity would give quite near enough results), and that this ratio should not be used in the way you have done without some qualifying factor or statement being appended to it every time it is mentioned.—Yours faithfully,

R. S. POTTER.

97, Belgrave Road, Hford, August 4th, 1905.

[It is obvious that 'our correspondent's definition of an ideally chromatic plate is one in which there is equal sensitiveness throughout the spectrum, and he ignores the fact that the luminosity of yellow and blue is practically 10 to 1, taking the spectrum as the standard. Therefore, to obtain "negatives in which the opacity was proportional to the luminosity throughout," this should be the ratio of sensitiveness. The objection to Mr. Mees' light is, as we have already pointed out, uncalled for because it approximates very closely to daylight, and in practice plates are exposed to daylight and not to patches of colour of equal luminosity. If the sensitiveness behind the blue filter is stated to be 100 and that behind the yellow filter is 10, it is obvious to represent the luminosities correctly we must screen down the blue till it bears the correct ratio to yellow, and Mr. Mees' results tell us exactly how much screening down we must resort to, with each plate that we have so far given a reading for, and as when giving these readings we have invariably stated that they have been made by Mr. Kenneth Mees, it is necessarily inferred that they are by the method which he has adopted. Hence is fulfilled, it seems to us, the final requirement of our correspondent's letter, namely, "that this ratio should not be used in the way you have done without some qualifying factor or statement being appended to it every time it is mentioned."—Eds., B.J.P.]

THE CELLULOID HAIR COMB.

To the Editors.

Gentlemen,—It may interest you and some of your readers to hear of an authenticated case of a fire caused by the ignition of celluloid combs in a shop window.

Mr. Brooks, of 264, Lavender Hill, Clapham Junction, keeps a hair-dresser's and tobacconist's shop at the address named. The shop is a double-fronted one. The left window was set out with toilet articles, including a number of celluloid combs and hair ornaments, etc. Last Sunday morning, in the window facing south-east, the celluloid articles ignited through the heat caused by the sun shining through the glass on to them, and the whole window blazed up and was burnt out in less than ten minutes. The sun-blind not being down and the shop closed helped, of course, to intensify the sun's rays, and there must have been quite 160 deg. in the window if not more. The fire broke the plate glass and a large mirror in the window, but did not do any damage in the shop otherwise.—Yours, etc.,

E. FENSKE.

188, Falcon Road, Clapham Junction, S.W.
August 8, 1905.

THE CHEAP COPIES GRIEVANCE.

To the Editors.

Gentlemen,—Why should not photographers adopt the system of requesting their sitters to sign an order form before sitting, requesting a negative to be taken, proofs furnished, and conveying the right to the operator—if necessary, a clause to be inserted stating that no publication of the portrait would take place without the sitter's permission? A very large proportion of sitters would do this without any trouble or question. The few who would object could state their reason for so objecting, and the photographer could then hold out for a higher rate. This would effectively meet the case of those who have a negative taken and proofs supplied in a good studio, and have the proofs reproduced cheaply elsewhere.—Yours truly,

F. SKEEN.

1, Chatham Street, Colombo, Ceylon.

July 18, 1905.

The system has often been mooted, but our feeling is that the best plan of charging for, and if necessary suing a sitter what he has had, is the one which will work best in the long run. It is easy to foresee a good deal of unpleasant aspersions cast on the photographer who takes the case of a cheap copyist into his hands on the basis that the sitter has assigned the copyright to him. There may be cases when such a transaction can be creditably made, but to adopt it as a general practice would place photographers very unfavourably in the eyes of the public.—Eds., B.J.P.]

THREE-COLOUR STEREOSCOPY.

To the Editors.

Gentlemen,—As I am aware you take a deep interest in stereoscopic work, I send you by this mail, under separate cover, a slide mounted from one of my trichrome stereograms, which I hope you will accept.

I am in the habit of reading the numerous articles on colour photography in the "British Journal" as well as in the Almanacks, and I may say I thus frequently gathered hints to improve my work.

I take negatives for three-colour work, only from nature, avoiding paintings, water-colour or coloured prints, as the truth of the colours of their photo reproduction can only be appreciated when comparing with the original. Such is not the case with subjects of nature, the colours of which are generally known by everybody.

I also selected the stereoscopic form of image, same giving sensations of solidity, and besides excludes any attempt to retouch or paint, but gives the pure synthesis resulting from printing the three negatives.—I am, dear sir, yours faithfully,

VICTOR SELLE.

42 Rue des Drapiers, Bruxelles,

Aug. 2nd, 1905.

[We are pleased to receive token of our correspondent's esteem, particularly as it takes the form of an excellent piece of pigment trichromy on paper.—Eds., B.J.P.]

DEATH OF MR. E. H. FITCH.—We very much regret to record the death of Mr. Edgar Henry Fitch, which took place at Brixton on July 25, after a long and painful illness. Mr. Fitch was associated with the celluloid film manufacture from its early days, and up to the time of his decease was actively engaged in the business which he conducted at Fullwood's Rents, High Holborn, W.C. His interest in photography sprang from those of his father, Noel E. Fitch, who was a well-known amateur photographer of the last generation, an active member of the old South London Society, and for some time its treasurer. We join our regrets to those of many others by whom the deceased gentleman was known and respected.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

L. Berry, 29, Chapel Street, Chorley. Two Photographs of the Rev. Father C. E. Slater.
H. Terry & Sons, Lodge Road, Redditch. Four Photographs—Group of small metal work. Group of bent wire work. Group of steel springs. Heap of steel springs.
W. Sbeeran, Watercastle, Durtow, Queen's Co., Ireland. Five Photographs—Abbeyleix House. Main Street, Abbeyleix. Abbeyleix Fair. Old Bridge, River Vore, Abbeyleix. Tea House, Abbeyleix.
J. H. Cartwright, 171, Orford Lane, Warrington. Photograph, Pictorial Post Card with seven local views of Warrington.
J. Clapperton, 23, Albert Place, Abbotsford Road, Galashiels. Photograph of marble bust of Sir W. Scott.

RETOUCHING (Balgownie, N., Queenstown, Cape Colony).—Your retouching, whilst very good indeed, is not equal to the best we have seen. The face, worked two years ago, has lost much of its ruggedness and strength of character through over-stippling and lifting of the lead. We should think you laboured over the subject, but you do not state the time taken. Softer, looser, and bolder treatment would have improved matters. The neck looks twisted and unpleasant, although correct in the unretouched. This negative was not a difficult subject, being well modelled in its unretouched state. The test is to make something good out of a really defective and poor negative. Since this effort you appear to be passing through a transition stage, as shown by the other specimens, which are more in the English style, although not fine and soft enough in the working for the subjects. The management of the shadows under child's eyes is bad, and they are unevenly balanced. (2) You have yourself criticised your evident lack of knowledge in knife work or reducing agent. Your retouching is nearly first-class, but you might try us again in about twelve months' time, and under conditions as advised to "General Assistant," in our issue of August 4th, 1905.

RESIDUES.—Which is the best way to throw down the silver in used hypo baths, and how can I make sure that it has settled?—H. H.

Add "liver of sulphur" (potassium sulphide). The silver is thrown down as a black sludge of silver sulphide. Add a little more sulphide solution to some of the clear supernatant bath; if it remains clear, the silver is all down, if not, further liver of sulphur must be added to the bulk.

SALARY.—1. What is average salary for landscape operator for publisher? 2. What amount of expenses allowed per day? 3. How many half-negatives of popular subjects, in town, fairly near together, for post-card or similar use, would be usually expected to be taken in a week? 4. Does "out of pocket expenses" mean, in addition to railway fares and porterage, all hotel expenses of board and lodge? Presuming, which is the case to me, that the operator has a home and family to keep.—ALPHA.

1. There are no fixed salaries, they depend upon the abilities of the operators. 2. There is also no fixed rule as to expenses, they are a matter of mutual arrangement between

the parties. 3. This question is unanswerable, for it is obvious that so much depends upon the weather, the light, and the time it may take to get from one subject to another.

4. Yes. 5. Yes, we should say it does.

POSTCARDS.—Would you kindly inform me the cheapest process to produce picture postcards? I may only want 100 of each, so block would be too expensive. I would like to sell at 1d. each. Is colotype best? If so, where could I obtain instructions in same? Is apparatus expensive, and would it pay at above price.—LEAMINGTON.

For such a small number it will certainly not pay you to set up a colotype press, etc. Your best plan is to produce a bromide or gaslight card. If of the size sold as midget, micro, etc., the card can retail at a penny.

AGREEMENT FOR SERVICES.—We are writing to ask your advice and shall be glad if you will kindly let us know what you think about the following subject:—Some months ago we took on a canvasser at a salary and commission, and he signed an agreement (a copy of which enclosed). He left us, giving us a week's notice, and then started with another photographer in this town. We saw the photographer, showed him the agreement, and he dismissed the man, who was not heard of again for some time. One day he came back and asked us for work, and we then took him on again on the same terms, but not asking him to sign an agreement this time. He this time left without notice, and is working for the same photographer, who now refuses to dismiss him, as he says the agreement was cancelled by working here again. The man is a very good canvasser, and is doing us a lot of harm, or we should not trouble about him. Can we get an injunction to stop him working? Can we, in any way, compel the photographer to dismiss him?—INJUNCTION.

The agreement seems to be a curiously-worded one, as the man, in one part of it, agrees not to enter the services of anyone or trade on his own account while in your employment. In agreements of this sort it is usual to have a penalty named which is to be forfeited in case of a breach. You cannot compel the other photographer to dismiss the man. Your remedy, if you have one, is against the man himself, for damages. Your best way will be to consult a solicitor, showing him the agreement.

VARNISH.—Can you oblige me with the name, or formula, of a suitable varnish for using after transferring carbons on china, so that the pieces can be washed?—EN AVANT.

The best varnish we know for the purpose is "Japon. Enamel 105." It is supplied by the Crane Chemical Co., 22, Newhall Street, Birmingham.

SEPIA TONES WITH PLATINUM.—I shall be obliged if you can favour me in your columns with a bath to obtain a cold sepia tone on collodio-chloride paper. I have been in the habit of using the ordinary plat. and phosphoric acid bath, but the tones got are either too rusty or else the common brown. The paper used is Solar. Thanking you in anticipation. — EXPERIMENTALIST.

Try diluting the bath with water. Use 12 or 15 ounces instead of 10 ounces, or in this proportion. The phosphate bath should then give you the desired sepia tone.

S. E.—You do not state the working aperture of the lens. Assuming this to be $f/11$, most likely, the distance beyond which all objects are in focus is 15 ft., if $f/8$, 21 ft. (2.) As above (3.) If working correctly to its marking, the magnifier should give any object nearer than 9 ft. as out of focus. (4.) On the side remote from the camera, a considerable distance, the-

retically an infinite distance: on the near side, the range is practically nil. (5.) No. As the focal length is increased, the working aperture is also increased and exposure may be less.

ORTHO.—All the films you name are, we believe, sensitised with erythrosine and not eosine or fluorescine. Your most likely trouble is in errors in exposure, and you are under-exposing through the orange screen, the result is that your negative is too thin everywhere, and therefore in printing in blue you get an excess of blue. You give no information as to the screens or plates that you are using, but if you are using an isochromatic plate with an orange screen to obtain the blue printing negative, your results are likely to be wrong, because unless you give very long exposures, you cannot possibly get sufficient density. For the orange screen, which gives you the blue printing plate you must use a panchromatic, or red sensitive plate, that is assuming you are employing the ordinary stained film process.

THE Right to One's Face.—A case came up in the American Courts not so long ago in which it was ruled that one cannot restrain a photographer from taking and using a photograph of oneself, saving only in the case when by so doing he exposes himself to action for libel. Hence, an incident such as the following, reported in the "Photographer," may occur frequently in the States:—"Harry Lehr, the well-known society man, had an argument with a photographer on Bellevue Avenue, Newport, recently because the man had taken his picture. Alighting from a motor, Mr. Lehr and party started for the Casino door, and the camera was aimed at them, and the plate exposed. Mr. Lehr saw the taking of the picture, and as the man pressed the button he raised a bundle in front of his face, and then made a rush for the man. Mr. Lehr did not lose his temper, but gently told the man that he guessed he would "have to take the camera now." The man replied, "I guess not." Seeing that he could do nothing with the photographer, Lehr went for a policeman to make a complaint, and while talking to the policeman the artist again took his picture. This made Lehr angry, and he sent for the chief of the police, telling that official that the man had taken his picture. The chief informed Lehr that he was powerless to act in the matter, but said that he would ask the man to stop, which he did. This in a measure satisfied Lehr, but he did not get the man's camera, and the man has Lehr's picture. Shortly after that a number of young women were photographed by the camera man, and they complained to a young man in the party, who went and threatened to kick the camera to pieces, but the threat was not carried out. There is no law to prevent the taking of pictures on the street, although the cottagers have tried for years to have it stopped.

EX CATHEDRA.

Although many members of our Royal Family are amateur photographers none so practical an interest in photography as Queen Alexandra. Her small hand camera is a familiar sight at the numerous outdoor functions she attends, and she apparently derives as much pleasure in portraying the interesting scenes she witnesses, and as keen a delight in photographing the crowds that gather to greet her, as the energetic press photographer takes in snap-shooting Majesty. A unique opportunity is now afforded the public of seeing some of the Queen's photographic work. "Graphic" for August 19, 26, and September 2 will contain special supplements consisting of a series of reproductions of photographic studies taken by her Majesty Sandringham, Marlborough House, Copenhagen, and the Coast of Scotland. These pictures will not only be interesting from the fact of their Royal authorship, but as admirable specimens of artistically chosen incidents and scenes. Further particulars of the first of these special numbers will be found in our advertisement pages.

From the pages of the "Scientific American" we learn that Professor Lowell and his assistants at the Flagstaff Observatory succeeded in recording on a bioscope film photographs of the enigmatic canals of the planet Mars. A monophotographic apparatus was devised which, excellent though it was, left much to be desired, chiefly so far as automatic motion was concerned, inasmuch as the camera had to be worked by hand. Still, by diaphragm-down the objective to suit the atmospheric currents at time of observation, the experiment succeeded. An excellent reproduction of a part of one of the films is reproduced, and side by side with it is placed a drawing

made by Prof. Lowell shortly before the camera was put on. This serves the double purpose of showing the confirmation by the photograph of the existence of the canals, and at the same time of acting as a chart. Our contemporary says:—"The astronomical importance of this feat of photographing the canals can hardly be overestimated. A hot controversy may now be considered definitely settled—a controversy in which most of the eminent astronomers of the world have taken part, either in absolutely denying the existence of Martian canals, or in advocating not only their existence, but also in regarding them as evidences of life on a neighbouring world.

Losses through the Post Office.

Complaints are frequently made of the loss of letters and parcels sent through the post, and often by photographers of packets of photographs, but is it always the fault of the Post Office? The annual report of the Postmaster-General has just been issued, and very interesting reading it is. For example, it shows that no less than 734,500,000 postcards were sent through the post during the year, being an increase of 19.7 per cent. on the previous year. This increase is attributed largely to the increased use of picture postcards. The most astonishing part of the report is that referring to the number of packets posted with insufficient addresses, and with no address at all. It says that the number of registered letters, and letters containing property sent through the post with insufficient addressing was 315,965. These letters contained £17,830 in cash and banknotes, and £622,123 in bills, cheques, money orders, postal orders, and stamps. One packet contained jewellery whose value exceeded £2,000. The number of letters containing valuable contents posted with no address at all was 4,507, the contents including £157 in cash and banknotes, and £9,412 in various forms of remittances, and it was found possible to restore the greater number of these letters to the senders. It seems incredible that so many letters and parcels with valuable contents should be posted without any address at all, or with only insufficient ones. Also that they should be so insufficiently secured that the contents get loose in their passage through the post. The fact that so much of this valuable property was restored to the careless senders speaks much for the honesty and ability of the Post Office employees.

Sending Negatives by Post.

Apart from occasional losses in the post complained of by photographers, who, doubtless, by studying the above figures will think less badly of the department, losses frequently arise, for which the photographer, by no line of argument, can blame anybody but himself. We refer to the case of

negatives getting smashed in transit. We have on more than one occasion received an envelope full of bits of broken glass and film, and an accompanying letter containing the naive enquiry, "Can you tell me what is the matter with the enclosed negative?" The answer is, of course, obvious. The negative has come into precipitate contact with some hard substance, and the glass, being devoid of ductility, has suffered disintegration. It may, of course, have been trodden on, or squeezed into an awkward corner of the mail-bag. In any case, to send a glass negative through the post with no further packing except that afforded by a paper envelope is to court disaster. And yet this is done again and again, and the unfortunate Post Office gets the blame. Negatives for conveyance by either letter-post or parcels-post should be first carefully wrapped in soft tissue paper or placed in one of the prepared envelopes specially sold for the purpose. It should then be placed between several pieces of stiff corrugated paper, cut to size and inserted in a plate-box, with more packing of tissue paper if necessary. The plate-box is wrapped in several thicknesses of the corrugated paper, and the ends well covered. If the whole parcel is now given a final cover of brown paper, and the address is written on a tag label attached to the package, it ought to travel with perfect safety through most of the dangers that beset such things en route. If the negative is particularly valuable, further protection can be assured by placing the brown-paper parcel, with the addition of extra packing, in a light wooden box. We have frequently sent negatives 15 in. by 12 in. and larger per parcel post packed in this manner, and they have come to no harm.

The Free Portrait Swindle at Home.

the suburbs, but with somewhat different tactics. The touts, sometimes stylishly dressed women, call at private houses and politely offer to do an enlargement free, with the usual tale that it is as an advertisement for the firm, etc. If no money can be drawn at the time the photograph is still taken with the promise that a rough proof of the enlargement will be submitted in a few days. In due course a bromide enlargement is shown, and the demand made for the price of a frame, as the picture will not be supplied without the amount being generally from fifteen shillings to a pound. If this is refused, bullying and threats of county-court proceedings follow. In the case of nervous women, who are the chief dupes, the money is often extracted. Sometimes the unlucky dupe loses the original photograph entrusted to the tout unless the money demanded for a worthless frame, etc., is forthcoming. As the photograph is too often one of a departed relative, and, perhaps, the only one its owner has, the money is frequently paid rather than lose the original. The price of the frame, which is of the commonest description, amply covers the cost of the enlargement, and yields a very good profit. A friend who resides in the suburbs has just related to us the following:—A well-dressed man called at the house and stated he was representing the — Studio. He then recited the usual formula about doing free enlargements as an advertisement, etc. This was duly listened to, and then our friend, in a quiet way, informed the man that he quite understood the game, and that the thing would not work with him. That was sufficient: the man was profuse with apologies for troubling, and said he had been sent to the district, and was simply doing his duty. It was noted that he did not call at any more houses in that road.

The free portrait swindle of Tanqueray in Paris has been frequently referred to in these columns, yet it is still being largely practised here, particularly in

Light on the Waters.

In another column a correspondent told of his difficulties in dealing with the extreme actinicity of the light when photographing sailing vessels and such subjects at this time of year when the sun is shining brightly. The conditions that govern photography on the sea during the summer months are altogether different to those that apply to any other form of camera work, and up to the end of August every precaution will be necessary to avoid over-exposure. Exposure meters give only an approximate idea of the brief exposures necessary, as it will usually be found that the test paper tints so rapidly that calculations are difficult, and even then it is found that one-fifth to one-twentieth of the indicated exposure usually suffice. We have during the past week made exposures on Barnet ortho films, and, using a yellow screen with $f/16$ and focal plane shutter exposures of 1-130 second, have had considerable over-exposure. Marion-Iso plates and Kodak films have also given over-exposure under similar conditions, the subjects being racing yachts, with their canvas illuminated by brilliant sunshine. The blue sky and choppy sea, reflecting nearly as much light as the sky itself, also tending to shorten the exposure, which, under the circumstances, could easily have been one-half of that given. It will be found, however, that the light will drop considerably in actinicity value during the month of September, and exposures that are now possible at the seaside will be impracticable in a few week's time. But, nevertheless, photographs taken either on or by the sea always need considerably shorter exposures than those of landscapes or any other outdoor subjects, irrespective of the time of year.

Photographing Fortifications.

We have on several occasions cautioned English tourists on the Continent against taking photographs in the neighbourhood of fortifications, or they might find themselves in an unpleasant position if noticed by an enterprising official anxious of promotion. It may not be known to all amateurs that taking photographs of English fortifications without authority may also land them in difficulties. Only last week a German photographer who has lived for thirty years at Sheerness was charged with attempting to take a photograph of the Ravilin Battery, and the case was remanded. In dismissing the charge a couple of days afterwards, the Stipendiary remarked that the proceedings were absolutely right and proper in the interests of the country. If an unpleasantness such as this arises with one who has lived for thirty years in the neighbourhood, it should serve as a warning to strangers when using their cameras in the proximity of fortifications in any part of Great Britain. As a rule, amateurs in search of artistic pictures are scarcely likely to point their cameras at fortifications, for they are by no means picturesque. Still, the subjects may be interesting to some, and if they desire to obtain photographs of them they should take the precaution of asking permission of the commanding officer before attempting to do so. On the Continent they are much more strict in this matter than we are here, and not a few tourists have had at times got themselves into trouble through the incautious use, or even carrying, a camera in the neighbourhood of fortifications, particularly on the Franco-German frontiers. It is not pleasant for a tourist on a short holiday to have to spend a day, perhaps two, in durance vile, and that has happened to several. We have on more than one occasion before advised all visiting the Continent to provide themselves with passports before starting, although now passports are not required in most Continental countries. They may be

and without difficulty at the Foreign Office, and the cost quite nominal. A passport will not, of course, prevent a photographic tourist from getting himself into difficulties, but it will help very materially in getting him out them by proving his *bonâ fides*.

Portraits in Natural Colours.

We notice in one of our German contemporaries the announcement that a studio has been opened in Berlin specially for photographs in natural colours on paper. The studio is about fifteen yards long and five and a half yards wide, and is fitted with ribbed glass windows and of. About six feet of the roof and side glass is movable, thus giving a brilliant and open-air lighting, and also saving away with any loss of light by the absorption of the glass. The camera is fitted with a repeating back for the three exposures, and the colour filters are placed just in front of the plate. The printing process adopted is that of superimposed carbon tissues, in, of course, the correct colours—red, yellow, and blue—the same as are placed in the market here by the Rotary Photographic Company. Not only portraiture, but the reproduction of oil paintings and other coloured objects will be undertaken, and special arrangements have been made to give instructions in the process. We should think that what is possible in Berlin might also be possible in London or England, and at the prices charged, namely, fifty shillings for two cabinets, there ought to be profit in it.

Development in P.O.P.

In the early days of P.O.P. many formulæ were given for developing faintly-printed proofs, all of which were tried, and which practically relied on the phenomenon of physical development—that is to say, the silver salts in the film were more or less dissolved by the developer and immediately reduced to the metallic state by the reducing agent and the silver deposited in the image. The disadvantage of this process was the liability to general stain, due to the silver being deposited all over the print rather than locally on the image, and, further, the unpleasant tones which were frequently obtained. A distinct advance was made when Mr. W. J. Wilson, of the Paget Prize Plate Company, suggested the conversion of the whole of the free silver salts into bromide, and the subsequent use of an alkaline developer. Of late there has been a revival of the acid physical development, particularly with metal acidified with glacial acetic acid, and on some papers excellent results are obtainable. The article which we publish elsewhere on this subject is interesting, as it is, far as we are aware, the first attempt to control the results obtainable by the addition of various salts and acids.

NEGLECTED BUSINESS.

We suppose there are very few photographers who cannot sympathize with us in deploring the agencies which of late years in one way or another have "cut into" photography. The business of the photographer has been assailed at a good many points. The picture-postcard, since the market has been flooded with cards of every place and thing in heaven and earth, has practically destroyed the trade in views of his locality, which many a photographer could have accounted an appreciable source of revenue. And the postcard has had a further injurious effect in offering the opportunity for the production of the cheapest and poorest

kind of photography, done either direct or from the work of reputable photographers. We know the cheap postcard and the other forms of cut-price photograph as well as we know the cheap enlargement in its various degrees of badness. Considered as value for money, these products cannot be unreservedly in demand, and it is difficult to exaggerate their evil effects on the commercial and professional status of the photographer.

Our object now, however, is not to dilate on these adverse tendencies in the profession, but to insist on one or two directions in which profit and prestige may be sought, and which a very large number of photographers seem to ignore or to be ignorant of. There is one basic fact that appears to be lost sight of in the management of studios—that is, the variety of finished results to be extracted from the raw product—the negative. Few businesses offer the opportunity for altering the final article as may seem commercially most expedient. No need for us to enumerate the changes which can be rung on printing process, size of picture, and style of production; we would here call attention particularly to a class of business which should be the photographer's, which can be extremely profitable to him, but which—we have good grounds for saying it—he is extremely slow to take up. We refer to the miniature, photographic or non-photographic, and producible in styles to suit every taste and purse.

We should not make the insinuation of neglect against photographers if we were not certain that there was business in this particular specialty, but that there is we have the strongest evidence, and that others outside the photographic profession are profiting by it is equally certain. For commercial purposes we can assume a miniature to be any small picture, or photograph, from the "photo-button" to the genuine hand-painted ivory. Between these two is a range of articles at any and every price. We need say little about the ivory miniature which sells from ten guineas and upwards, because the businesses in which it can be offered are, for the most part, in the hands of men fully alive to its value. The miniature is almost invariably extra business, and it would very possibly surprise those who have left it out of their programme to discover the total which it may amount to at the end of the year. For the middle-class and lower-class business the miniature can change its form. It can be as cheap as you like, and assume the shape of a locket, pendant, brooch, or scarf-pin. The fact that active business is done in this "photographic jewellery" by jewellers and silversmiths in the very towns where the photographer complains of slackness in custom is a reason for believing that tightness of money is not the only cause of diminished receipts. Business of this kind is rightly the photographer's, but if he does not look after it someone else will.

The case would be different, and exception might be taken to our criticisms, if the introduction of the miniature as a specialty involved the photographer in special staff or equipment, but the facilities offered by several firms working for the profession in this special line places the photographer in a favourable position to deal with the smallest and largest volume of the business. That it is of advantage to push such special lines must surely be the conclusion of the man who surveys the situation. When one's competitors within and without are contending for pre-eminence in supplying a very ordinary article at an extraordinary low price, it is sound policy to try one's public with something different.

A PHOTOGRAPHER OF CHILDREN.

AGREEABLY to our promise of last week, we would interest our readers in the work and method of another New York photographer, at present in Europe to see what is being done, photographically, in the Old World. Such success as Mr. E. B. Core has attained is purely individual, the essential personality of the man finding the very field it needed.

A Pioneer.

American photographers are to the fore this year. A few weeks since we met "Byron, N.Y.," the veteran flashlight worker, who a generation ago found that the English public were too slow to appreciate a new thing, and so crossed to New York to score success. And more recently, while we were chasing Pirie Macdonald, we ran across Mr. E. B. Core, the New York photographer who banishes men and women alike from his studio, and limits his energies to portraits of children. Mr. Core is a man interesting to photographers in that he is a pioneer, if not the pioneer, in specialist portraiture. It is just about eight years since he set the example, followed by others, of relinquishing a successful business to sink or swim in a new venture. He gave up a well-established connection in Cincinnati, where his work had won him an enviable reputation, and came east some six hundred miles or more to be the photographer of New York's children.

The Man and His Studio.

Mr. Core does not strike one as an aggressive man. His manner with adults is gentle almost to bashfulness, but he has a fund of quiet enthusiasm, and he is a capable business man. His venture was an immediate success; eight years have attested that it is also a permanent one. He believes that it is not difficult to build up a successful business for the photographing of children; but then, few things are difficult to the man who is master of them. His success has been merely that of the right man in the right place. In connection with this he mentions a curious fact. In spite of the undoubted and much-talked-of success of a few men venturing in special lines, there has been a noticeable lack of imitators. Why this should be is a little difficult to say. It would seem as if every city of 100,000 people—and there are probably a score of such in the States—could support its own children's photographer. And yet photographers are not forthcoming to bid for exclusive business.

His studio is fitted with a couple of cameras, chairs, and a few backgrounds. The usual accessories are absent, but the place overflows with toys. Toys are a wonderful introduction, and with toys and E. B. Core working in conjunction there is a combination which few children can resist. If the real skin bear cannot emit growls which are sufficiently distinctive, Mr. Core will oblige with a real live impersonation. The first interest is the interest of the child; and in gaining this the natural dignity which many children possess must be appreciatively considered. Some children will work loyally with the photographer, while others are full of a mischievous determination that no picture shall be taken.

The Method.

An assistant is placed at the camera to change plates and attend to details—often to make the exposures. Mr. Core is thus enabled to devote all his attention to his subject. Many a little active resister has left the studio confident that his efforts had been successful, little dreaming that ten or a dozen exposed plates have been passed on to the developing room. Mr. Core finds it good policy to make a fair number of exposures. His price for a dozen cabinets, from two negatives, is twenty dollars. A wide range of proofs often leads

to orders from more negatives, which means an increased price, and helps to increase the total number of prints ordered. And a considerable choice of pictures is necessary to a probable specialty of Mr. Core's, viz., a large sheet of paper on which a number of poses of the little subject are delicately vignettted. Mr. Core has but one relaxation of his rule "children only." Where necessary to the success of the picture he will include the mother.

The Stamp of Personality.

E. B. Core and Pirie Macdonald are one in their insistence on the individuality of the American photographer. All work which leaves his studio must be recognisable as his work. The printer may do the best grade of work, but if he has any style or preference of his own, it must be subordinate to the style of the studio. Core gets the credit for a good photograph, and he gets the blame for a bad one, and he is the one man responsible through every stage of procedure. The finished work is his, and must be so distinctive that his lay patron will recognise it as such.

Fraternity.

Mr. Core is appreciative when speaking of the English professional; but then, he is always quick to see the best in anyone's work, and he would rather praise another than speak of himself. Four years ago he filled the office of President of the Photographer's Association of America. The annual meeting that year was stamped with the personality of the president more than any meeting before or since. The convention, which was wont to be a huge social gathering, with a strong competitive exhibition of photographs, was turned into an "educational convention." For that year medals were abolished, and photographers asked to hang their pictures for honour only. As a result the show was strengthened, for many men of assured position, who declined the chances of competing for awards, agreed to send a display of their best work. For those who looked to medal-awarding as a gauge of the quality of their work, another aid was offered. When desired, two men, a painter and a photographer, wrote brief criticisms of an exhibit, and these criticisms were handed privately to the authors of the pictures. The speakers for that year chose subjects of distinctly educational value, and the profession at large approved the experiment. It was a practical demonstration of a healthy belief in the value of fraternity.

THE souvenir in "Commemoration of the Reception of Admiral Caillard and the Officers of the French Fleet by the Houses of Parliament" is a most elaborate and interesting volume, comprising ten views of the Houses of Parliament reproduced from negatives specially taken by Sir Benjamin Stone, M.P. Opposite each view appears descriptive matter in French, the letterpress being tastefully displayed in red and black. The binding is most artistic, the cover of white vellum being blocked in gold, with a laced design surrounding the inscription, in which are included the arms of the two Houses of Parliament. The volume has been produced by Messrs. Blades, East, and Blades, of 23, Abchurch Lane, E.C.

"La Propriété Immobilière," a Paris journal, has instituted a competition confined to amateurs, the subject of which is a village in the country or on the sea shore. Medals are offered, and the judges will be MM. Bucquet, Bourgeois, Puyo, Nansonty, Guimard, Wallon, Mareschal, Farge, and da Cunha. The right to reproduce the winning or any of the prints without fee is reserved by the promoters. The address of the journal is 8, Chaussée d'Antin, Paris.

HOW TO RETAIN THE LIKENESS WHEN RETOUCHING.

One of the earliest difficulties the young retoucher has to contend with is that of retaining a faithful likeness; and with any so-called competent retouchers we often find that whilst they may be adepts at making the much-coveted yet unnatural and unnecessary grain, their methods of obtaining it are such that the resemblance to the original is generally more or less impaired. I have often heard people praise the untouched photograph taken by some amateur because "it is just like so-and-so," and at the same time speak disparagingly of a photograph taken at a good studio because the likeness to the original was partially or totally lost. Photographers generally, especially employers, will agree with me that I am dealing with one of the most common failings of retouchers, and I want to show the reason why it is so and how it can be avoided. For it is possible to very much retouch a negative, and, indeed, to over-retouch it, as is often required for actresses and others of that ilk, without losing the natural personality of the subject.

A Basic Error of Retouchers.

First, then, the common method of retouching by working evenly across the features from one part or corner to the opposite end is radically wrong. For in doing so the difficulty of keeping the true balance of light and shade is enormous, and the tendency to take out detail which should not be touched is equal to it. Most retouchers either begin retouching at one corner and then work right across to another, or else commence at the nose or the highest light on the forehead or cheek and then gradually spread out over the face until the whole is covered. Others, again, work up some special feature first, and finish it before proceeding to another, or else do a bit here and there without system or method in doing so. But all these methods are wrong, for it is impossible to keep the natural balance of

light and shade exactly centralised, and to know what to take out or leave in.

A Method which Aids Retention of the Likeness.

The better method of procedure is to work *successively* from high lights through the half-tones to the shadows, as follows, viz.:—First look to the highest lights on the face. If these contain blemishes which, however, will not show on the print, or, in other words, which will not print through, it is better to leave them alone; for whilst working upon them may make the negative look more finished it will make the subject in the print less so. If the negative is somewhat hard, or strongly lighted, it is more than possible that none of the highest lights will need retouching at all; but if it is flat or weak, the highest points may be strengthened, and, as the rest of the negative is untouched, it is easy to keep them exactly of the same nature and position as they would have been had more contrast existed previously. For remember always to keep the *centres* (highest points of intensity) of light in their proper places.

The remaining high lights should then be attended to in the order of their density, and not according to their position, and all this should be done before the half-tones or shadows are touched, so that all the features are retouched methodically part by part. The half-tones are next attended to, commencing with those which will print lightest, and working with the others successively until the shadows are reached in turn and worked off in the same order. By working thus, the balances and centres of light and shade may be kept throughout, and only defects will be obliterated, whilst the modelling and character detail is retained with ease.

This way of working (which is more fully described in my book on retouching) is easily followed, and by doing so it is remarkable how little work is required to secure a beautifully-retouched negative when compared with the usual methods of working.

ARTHUR WHITING.

THE WEEK IN HISTORY.

Scott-Archer's Film—1855.

SCOTT-ARCHER, four years after his invention of the wet-collodion process, devised and patented an addition to it which has been a constant use for one purpose from that day to this. On Thursday next, exactly fifty years will have elapsed since his application for a patent was made, and the full specification (No. 1,194, 1855) is interesting reading as extolling even in these early days the virtues of a flexible film-negative. "The negative picture," he writes, "is produced in the ordinary manner upon the collodion film on a sheet of glass, and it is fixed and dried in the ordinary manner. I then pour over it, or dip it into a solution of guttapercha, and after draining off the excess, it is dried by a gentle heat, and leaves a nearly transparent film of guttapercha upon the collodion. If the film is not sufficiently thick this operation is repeated once or more times until a sufficiently thick film of guttapercha is formed. I then immerse the whole in water, which causes the collodion to separate from the glass, and I then remove the film or sheet of guttapercha with the collodion film firmly adhering or combined with it. These films or sheets are sufficiently transparent, and are tough and flexible, and may be handled without injury, and they may be preserved in a book or portfolio. I employ these films for producing the positives in the same manner that the ordinary glass negatives are employed. They may be placed with either

side in contact with the paper according as it is wished to obtain a correct picture or a reversed picture."

The Publication of Daguerreotype.

To-morrow precisely sixty-six years will have passed since the greatest day of Daguerre's life, for on August 19, 1839, his process was the subject of Arago's enthusiastic eulogy before the Academy of Sciences. Apparently the address itself did not describe the manipulatory details of the process, for in the printed account in the "Comptes Rendus" these latter figures as footnotes. They constitute the first recorded description of the Daguerreotype process.

The first Daguerreotype.

As there must be few photographers who have perused this archive of their art, I may perhaps quote somewhat liberally from Arago's footnotes:—

"In the process to which a grateful public has given the name 'Daguerreotype,' the surface upon which the picture is impressed is a full yellow. It is produced when a silver plate is exposed for some time in the upper part of the box to the vapours from a few fragments of iodine placed in the lower portion. No sign of image can be discerned on the plate when it is removed from the camera obscura. The yellowish film of iodide has received the image, but still appears perfectly uniform. But if the plate is exposed in a second box to a stream of mercury

vapour rising from a dish of that metal, heated by a spirit lamp to 75 deg. Centig., the most remarkable result is produced. The mercury deposits freely on those parts of the surface which have been exposed to bright light, but does not adhere to the unexposed parts. It affixes itself to the portions which represent the half tones in greater or less quantity, proportional to the action of light on those parts. By the light of a candle the operator can follow, step by step, the gradual formation of the image; the mercury vapour can be seen to trace the details of the image as though it were a brush of exquisite delicacy. The image of the camera thus reproduced, the further action of the light must be arrested. M. Daguerre does this by moving the plate in hyposulphite of soda, afterwards washing it with warm distilled water. According to M. Daguerre, it is better to produce the image on a plate of copper covered with silver than on a silver plate, a fact which suggests that electricity plays a part in these curious phenomena. The surface of the plate should be first rubbed down with pumice-stone and cleaned with dilute nitric acid. The useful part which the acid thus plays, suggests M. Pelouze, may be due to its removing the last molecules of copper."

The first Theories of Daguerreotype.

M. Arago passed from practice to theory. "In attempting to explain this singular process of M. Daguerre's," he writes, "the idea immediately suggests itself that where the light reaches the plate in the camera, it produces vapourisation of the iodine, that the metal is bared in this spot, and that during the next part of the process the mercury vapour has full access to the plate and produces a white and lustreless amalgam, that the washing with hyposulphite chemically removes those portions of the iodine not removed by light, with the result that the bare and mirror-like parts are left behind and produce the shadows of the picture. But this theory offers no solution of the formation of the beautifully-graduated half-tones obtained in M. Daguerre's process. A single fact, too, will prove that the process is not so easily explained. The plate does not perceptibly gain in weight after coating with its yellow film of iodide. The increase in weight, however, is quite distinct when the plate is treated with mercury. M. Pelouze has ascertained that after washing in hyposulphite the plate weighs less than it did at first in spite of the presence of some amalgam. The hyposulphite, therefore, removes some silver, and the chemical examination of the liquid shows this to be the case. To account for the action of light in M. Daguerre's process, we may assume that the silver plate becomes covered during the exposure to the mercury with particles of amalgam, that these particles are close together in the high lights, are less crowded in the half-tones, and absent from the shadows."

A Point in Emulsion Making.

A practical step forward in gelatine-emulsion making attains its twenty-sixth birthday on Tuesday next, for on August 22, 1879, Mr. George Mansfield published through THE BRITISH JOURNAL OF PHOTOGRAPHY a method which, though not new on paper, was first put into practical shape at this time. It was the principle of emulsifying the silver bromide in a little gelatine, of heating this emulsion to obtain sensitiveness, and, after washing, of adding the remainder (i.e., the chief portion) of the gelatine. This process was fully reported on in THE BRITISH JOURNAL OF PHOTOGRAPHY at the time, and the following data given for carrying it out:—

For five ounces of emulsion, take:—

Gelatine	5 grains.
Ammonium bromide	60 grains.
Silver nitrate	100 grains.
Water	5 ounces.

Dissolve the gelatine, bromide, and silver each in one ounce of warm water. When the gelatine is completely dissolved, add to it a small quantity—say, a drachm—of the bromide solution, and shake or stir well. Then add a similar quantity, pouring it in a thin stream, of the silver, and again agitate. Proceed in this manner, adding the bromide and silver alternately until the whole of each has been used, when, if ordinary care has been exercised, a thin but perfect emulsion of bromide of silver—the finest possible state of division—will be the result. The remaining two ounces of water may now be added; but it is better to omit it at this stage, as the gelatine will take up more during washing. We now come to the question of emulsification or digestion. Seeing the minute quantity of gelatine present to be injured by heat, there is no necessity to confine ourselves to the stereotyped "ninety degrees." We, in fact, simply place the bottle in a covered pan and raise it to the boiling point, as Mr. Mansfield recommends; and, singularly enough, for general purposes we have adopted the same length of time (ten minutes) as that gentleman during which the boiling is continued. There is very little doubt that the change which goes on in the state of the silver bromide under these conditions is quite as great as, under ordinary conditions, occurs in hours, or even days. That such is the case, we have proved, for an emulsion prepared in this manner and digested at a moderate temperature (110 degrees) for about five hours was found to have assumed a distinctly granular appearance, though for two or three hours no such change was apparent. In the ordinary method of emulsifying, with a full quantity of gelatine, a similar result would have required weeks.

HISTORICUS.

THE PHYSICAL DEVELOPMENT OF P.O.P.

THE following abstract of an article by Herr Schmidt, which appears in "Photographische Kunst," opens up new fields for experimentalists in this direction, as suggestions are made which are, so far as we are aware, distinctly novel.

An acid hydroquinone developer will give a range of tones from red to olive green, but blue and violet are not easy to obtain by mere development. An alcoholic solution of metal will also give excellent results; it works quickly and keeps well, but is rather more costly than pyro or hydroquinone. The metal is used in a 10 per cent. alcoholic solution—or rather mixture, for the whole of the metal does not dissolve, and the solution must be shaken up before dilution with water in the proportion of 1.100, which forms the actual developer. This gives a dirty greenish brown tone, and

very quickly causes general stain; if, however, 20 to 30 drops of a 20 per cent. chrome alum solution be added to every 100 parts of the metal developer, the whites are kept clean. The addition of a little glacial acetic acid gives a greenish black, which, with continued use of the developer and very short insolation, turns to black-brown. Instead of the glacial acetic acid, acetate of soda may also be used with equally good results.

Citric, oxalic, and tartaric acids added to the metal developer give each its special tone ranging from brown to reddish yellow. Citric acid gives excellent brown tones with a shade of rose, which cannot be obtained with any toning bath. Oxalic acid also gives brown tones, and prolongs development. Chrome alum also acts as a restrainer, and the tone is pure brown and the whites clean, and

the presence of tartaric acid it acts in the same way, and the tone yellowish brown, which becomes darker the longer the development continues.

The possible combinations between the various acids are, of course, innumerable, but a mixture of two acids does not apparently give one which may be called the mean of the two, but it always has a tendency to reddish-yellow.

Although an acetate gives the same results as acetic acid, it does not follow that the salts of the other acids will act in the same way, for instance, the oxalate of sodium does not act in the same way as oxalic acid, as it gives greenish tones. In conjunction with citric acid it gives an excellent pure olive tone, however. Phosphates act in the same way, though, as phosphoric acid, and cause a general fog, which is not prevented by chrome alum.

Traces of bichromate in the metol and acetic acid developer give beautiful bright brown tones, but without the acetic acid there is no developing action. Phosphoric acid, if used in a 15 per cent. solution, added to the acetic developer converts the olive tone into brown. Its action is peculiar, as it appears to fog the whole print, but yet develops the detail with the same contrast as the other developers, it may therefore be useful for artistic effects.

The following tables give a summary of the results attainable, though there are other factors that influence the tones.

ORIGINAL DEVELOPER 50 CCS. 1:1000 METOL SOLUTION.

Additions.	Development.	Tone.	Remarks.
Glacial acetic acid, 3 ccs.	Quick	Olive	Addition of 5 ccs.; 1:20 chrome alum solution gives more brilliant tone. Excellent.
Lead acetate	"	"	Nitrate may be used. Advisable.
Citric acid (1:5), 5 ccs.	Medium	Brown	As No. 1. Excellent.
Oxalic acid sat. sol., 10 drops	Slow	"	Worth trial.
Tartaric acid sat. sol., 3-5 ccs.	"	Yellow or yellow brown	As No. 1.
Acetic acid, citric acid (a little), chrome alum	"	Brownish red	Very commendable.
Citric acid (1:5), 5 ccs.; sodium oxalate	Medium	Greenish olive	Excellent.
Bichromate (1:50), 2-3 drops	Quick	Brown	Commendable.
Phosphoric acid (15 p.c.), 10 drops; chrome alum	Very quick	Dark green	Sodium phosphate can be used (for artistic work).

ORIGINAL DEVELOPER 50 CCS. PYRO SOL. 1:1000

Additions.	Development.	Tone.	Remarks.
Nil.....	Medium	Yellow brown	The same with 5-10 drops of acetone added.
Glacial acetic acid, 3 drops ..	Slow	"	The same with citric acid added.
Glacial acetic acid, 4 drops; chrome alum 8-10 drops	Medium	Bright brown	Commendable.
Glacial acetic acid, 5 ccs.; citric acid sol. (1:5) 5 ccs.; Pot. Bichrom. (1:50), 3-5 dps	"	Chocolate brown	Very commendable.
Glacial acetic acid, 10 drops; Pot. Bichrom., 1:50, 3 drops	Very quick	Olive	Commendable.
Citric acid sol. 1:5, 5 ccs.; Pot. Bichrom., 1:50, 3-5 dps	Quick	Greenish olive	Very commendable.
Oxalic acid sat. sol., 5 ccs.; Pot. Bichrom., 1:50, 3-5 dps	"	Sea-green	Commendable.
Copper citrate sol., 5 ccs.	Medium	Olive	For artistic work.

ORIGINAL DEVELOPER 50 CCS. HYDROQUINONE SOLUTION 1:100.

Addition.	Development.	Tone.	Remarks.
1. Nil	Very slow	Yellow brown	
2. Acetone, 5 drops	Slow	Brown	More acetone pure browns. Commendable.
3. Pot. Bichrom., 3 drops.....	"	Bright brown	Wash before fixing.
4. Pot. Bichrom., 6-10 drops; citric acid sol., 1:5, 10 ccs.	Very slow	Dark carmine	For artistic purposes.
5. Phosphoric acid (15 per cent.), 3 drops.	Slow	Brown	Very commendable.
6. Phosphoric Acid, 20 drops ...	"	Grey green	" "
7. Copper citrate sol. 10-15 ccs.	"	Olive	Chrome alum gives greater brilliancy. Very commendable.

Pyro stands midway between metol and hydroquinone, not only as regards the rapidity of development, but also as regards the variation of tone by certain additions. The use of a very dilute pyro solution 1:1000, gives, according to Liesegang, a beautiful chocolate brown that approaches warm black in the shadows, but this was only found to be the case with prints that were fairly strongly printed; if but a faint impression was obtained, a yellowish-brown tone was obtained. Unfortunately the tendency to fog is a great disadvantage with pyro. Acetic, citric, and tartaric acid do not alter the tone, but restrain development and prevent the fog. Good bright brown tones are obtained with a bath of pyro, acetic acid, and chrome alum. Oxalic acid plays a noteworthy part; in conjunction with pyro there is no development, and in conjunction with other substances it does good service as a restrainer.

Potassium bichromate and phosphoric acid can be used as accelerators, the addition of even a few drops of a saturated solution of bichromate accelerates considerably. Both give green to olive tones, but plenty of fog. If to the bath is added from ten to twenty times the quantity of oxalic acid as there is bichromate, beautiful sea-green tones result. Substituting acetic for oxalic acid, olive tones are given; the same applies to citric acid, which gives a tinge of rose. Acetic acid, in conjunction with a little bichromate and pyro, gives chocolate-brown tones, such as are unattainable with pyro, but as this tends to fog, it is advisable to add some citric acid.

To the pyro developer some copper and citrate solution, as used for toning bromides, was added, the actual composition being—

Copper sulphate	10 g.
Potassium citrate	50 g.
Water	1,000 c.c.s.

This gave an exceptionally artistic rendering in olive, which was accompanied by a slight fog. The pyro stock solution was a 6 per cent. aqueous solution with the addition of 40 drops of acetone to keep it. For hydroquinone a 10 per cent. solution was used as a stock solution, and some acetone was added to make it keep. When a print developed with the normal developer—that is, 1:100—and fixed, the tone obtained was a yellowish brown, with the acetone a warmer brown was obtained. Alcohol may be used instead of water. Citric and acetic acids and their salts produced no difference. Bichromate gives brown to dark green tones, but very little must be used, otherwise the prints must be washed before fixing, otherwise the traces of bichromate in conjunction with the hypo will act as a reducer. The longer the print is in the bath—that is to say, the fainter the original impression—the more the tone approaches chocolate-brown; but there is at the same time slight fog. Very beautiful dark carmine red tones are obtained if the quantity of bichromate is increased, and plenty of citric acid used; the print

must be only faintly printed and the development may take ten minutes.

If phosphoric acid is added, the tone varies according to the quantity used; a few drops give brown tones, with more a greyish green, and finally an olive tone is produced; if a lot is used a vigorous dark-green peculiar shimmering precipitate is produced. Small additions of acetone and bichomate hasten the development.

The addition of the copper-citrate solution gives excellent results, and the tone is olive, and is clearer with the addition of chrome alum.

The above remarks apply mainly to gelatino-chloride paper only, half printed under a normal negative. Faintly printed proofs give darker tones, tending towards green; strongly printed prints give brighter colours. A deeply printed proof gives more contrast than a weakly printed one, and concentrated developers tend to give darker tones, dilute developers brighter ones, and the latter work more softly than the others.

Some of the statements advanced by the author seem somewhat

curious, as, for instance, when he says that the more developing solution used the softer the image, which he explains is that the nascent silver has more opportunity to be suspended than when only a little developer is used.

Collodio-chloride papers, as a rule, give practically the same results as the gelatine papers, only the tones are colder, frequently darker and less brilliant. The metol and alcohol developer with chrome alum gives excellent brownish black results.

Not more than 50 ccs should be placed in a 9 by 12 dish at once, and not more than three or at the most four, prints should be developed therein, otherwise the precipitate of silver becomes too thick. Liesegang suggested the use of a fish glue to prevent this precipitation, but the author states that a dirty dish, such as has been used for developing and fixing, and only superficially cleaned, may be used for this process, and that the nascent silver is then deposited on the dirty places in the dish.

After development the prints may be either rinsed or transferred direct to the fixing bath, and an acid fixing bath is an advantage.

CONTROLLING EXPOSURE AND DEVELOPMENT IN MAKING BROMIDE ENLARGEMENTS.

Development.

SUPPOSE we were to make a "print meter" or densitometer by pasting over a piece of clean glass, pieces of semi-transparent paper, so that the first step has one thickness, the second two, the tenth ten, and so on up to the thirtieth, having thirty thicknesses, and suppose we put a piece of bromide paper behind and print through, giving such an exposure that on development to the limit (that is until it is not possible to develop any more), say step twenty-three has not printed, but twenty-two has just done so, twenty-one more so, and

II.

in the resulting print, and hence the line of gradation would be steeper. (See Fig. 2.)

A Negative of Standard Gradation.

If a negative is of exactly the right contrast—i.e., of standard gradation—and we give the correct exposure, whatever developer we employ, if we develop to the limit of reduction—i.e., until no more silver can be reduced—we will get a perfect rendering every time, as long as no fog sets in. The gradation of the negative is faithfully rendered, and, with modern bromide papers, fog will not set in as

Fig. 1.

so down; step eleven is greyish, step two is jet black. We can represent these deposits of silver in the print as steps where black is a very high step; deposit twenty-two is just an appreciable step.

Let us assume for argument sake that the exposures, through the thickness of paper, are in arithmetical progression, though for a "print meter" so constructed they would be in geometrical progression.

A Mental Picture.

We may then represent the result of development thus. (See Fig. 1.)

We see that the tops of the steps represent a straight line AB. This line denotes by its steepness the steepness of gradation of the print. Now if there were greater differences between the opacities or steps of the "print meter," that is, if the "print meter" or negative were harder, then there would be fewer steps between white and black

Fig. 2.

Fig. 3.

long as the developer is not too strong in alkali and not too warm. But if the gradation of the negative is not exactly right, we have to modify development to correct it, and to do this we must understand the action of developers exactly.

The Three Classes of Developers.

We may divide the developers into three classes:—

- (a) Those very slightly susceptible to the restraining action of potassium bromide, as rodinal, metol, paramidophenol. These have a high Watkins factor.
- (b) Intermediate. Amidol, weak pyro, kachin, ortol, eikonogen.
- (c) Those easily restrained. Hydroquinone, adurol, strong pyro, generally with low Watkins' factor.

We will discuss these separately.

- (a) Rodinal Class.—Unsusceptible to potass. bromide.

Most of us know the appearance of the image when developing a negative with metol or rodinal. The whole picture seems to flash

everywhere, and then blacken over and take an abnormal time at density when compared with the quick appearance. This is as should be expected with a developer of this class. In this the densities at any instant of development are proportional to the light actions—that is, all portions from the most exposed to the least exposed are being reduced relatively at the same rate. Development is uniform. If, now, we develop a print from the "print-meter" we can represent the different stages of development as shown in Fig. 3.

Now we see that by shortening the time of development we can get a softer print than normal, so we see how to decrease contrast in the case of a hard negative. In this case we use no bromide of potassium, or as little as possible, and use a developer of this class. When we develop the print, a bromide is set free in the developer. The reason is that when we reduce silver bromide to silver, the atom of bromine is liberated and combines with the base of the silver salt present, forming sodium bromide, or potassium bromide, according as a soda or potash is being employed as the alkali. In the case the bromide liberated does not appreciably affect development, seeing that rodinal is unsusceptible to it, and that this quantity is small.

We may here remark that the common phrase, "a developer which stops up detail before density," is unscientific and nonsense, seeing that detail is density, nothing more or less than pure silver. We do not rather to talk of such a developer as one which develops gradually.

Intermediate.—These developers are intermediate in character between (a) and (c).

Adurol Class.—Very susceptible to potass. bromide. The action of potass. bromide in a developer susceptible to it is to hold back portions of the latent image which have been least acted on by light. It has very little action on those much acted on by light.

Hence, in a bromide print the effect is that the shadows or blacks are free play, but the whites and greys are more or less held back. The holding-back action gradually passes off, and if we develop to the limit of reduction we get the same result as if we had used no potass. bromide, and developed to the limit.

Now, most of us know the appearance of a negative developed in a fairly strong pyro-soda developer containing a soluble bromide, and high lights (where there is most light action) in the case of a negative come up first, then the half-tones, and ultimately the shadows. In this we recognise the falling off of the holding-back action of the bromide. This is scientifically known as "the regression of the bromide." Even if we add no bromide to the developer we will see this appearance, though it will be very rapid, the regression being very rapid, as the bromide set free by development is very small. In the case of a print, of course it is the shadows or blacks which appear first, then the half-tones, then those tones bordering on whites.

When I wish to employ a restrained developer I find Schering's rodinal very convenient, using the formula given in the box, with the addition of potass. bromide:—

Adurol	3 drms	I use equal parts of A, B,
Sod. sulphite cryst ...	3 oz.	
Water	19 oz.	To the mixture add 2 gr.
Potass carbonate	2½ oz.	
Water	19 oz.	

Thus, A 1 oz., B 1 oz., water 1 oz. Ten per cent. potass. bromide, 60 minims.

We will represent graphically a print in the different stages of development when using such a developer. Suppose we use the print-meter again, and give as before such an exposure, that if the print were developed to the limit, step 2 would be jet-black, while step 22 just develop. Now, suppose we develop it in this restrained

adurol developer (see Fig. 4). The first step to appear will be No. 2. A little on, say when step two is between grey and white, step seven may have appeared. Then, when two is grey—i.e., midway between black and white—step eleven may have appeared. Then, when two is black—that is, when all the silver capable of being reduced in step two is reduced—step fifteen may have appeared. We see that the gradation of the print at any stage of development is represented

Fig. 4.

by a line, which is continually shifting up and shifting to the left—in fact, it is revolving about a point below the abscissa or initial line.

We also see that the line AC, obtained when step two has just developed to the limit, is steeper than the final limit line AB; hence gradation is steeper at this period. The steps sixteen to twenty-two are being held back by the restraining action of the bromide.

If we go on developing, step two cannot get any taller, as it has reached the limit; hence the gradation line cannot shift upwards, but it can still shift to the left towards B, and this it does, the restraining effect of the bromide passing off until ultimately it coincides with AB.

Suppose, now, our negative were too flat—that is, suppose our print meter were too flat in gradation, and that, as before, we gave the print such an exposure that step twenty-two just printed and twenty-three did not (see Fig. 5). Now, if we developed the print to the limit, step twenty-three would be white, but step two would not be black, but a grey-black (see E); the print would then appear flat. The dotted line EC would represent such a print. Now, if we want to increase contrast we must make our blacks really black and not grey-blacks, and yet preserve our whites, white. To do this, evidently, we must give more exposure, because step two has been developed to the limit, and is only grey-black, and needs more silver to become black. Now, if we give more exposure we must hold our whites back if we want to preserve them, and this we do by using the restraining action of potass. bromide. So that to increase contrast we must over-expose and use a restrained developer.

Fig. 5 represents what occurs in development. AB represents the limit of development, and C the required line; the other lines repre-

Fig. 5.

sent the intermediate lines. If we went on developing our whites would become dirty. If we put this print into rodinal the whole picture would flash up—and the whites would be dirty. So to understand the theory of development is to be able to allow exactly for the idiosyncrasies of the different papers and get any result desired—for instance, if we find a certain paper too soft we know how to increase the contrasts.

N. C. BACK.

[The concluding portion of this paper will be given next week.—Ed. B.J.P.]

SOME NEW SENSITISERS.

HERR VALENTA, of Vienna, publishes in the current issue of the "Photographische Korrespondenz" the following results of his experiments with some new dyes, samples of which were supplied to him by Meister, Lucius, and Brünig (M. L. Br.) and Fr. Bayer and Co. (By.). Some were tried with collodion emulsion as well as dry plates, and in the former case alcoholic solutions of the dyes was added to the emulsion. In all cases the actual German names are given, and the name of the maker in brackets. Alkaliechtgrün B. (By.), easily soluble in water and alcohol, sensitises vigorously with long exposure in yellow and yellowish green (ends abruptly at D, fades off towards E), and in the red (narrow and sharply defined band at C). Amidonaphtholrot G; 2 B and 6 B (M. L. Br.) give in strong dilution 1.50,000 a band, which is abrupt towards the less refrangible end, from D $\frac{1}{2}$ C to beyond D $\frac{1}{2}$ E. Alizarin-Irosol R (By.) sensitises in the red; the band extends with long exposure from B to C $\frac{1}{2}$ D (maximum at C). Brillanthodulinviolett R (By.) sensitises gelatino-bromide very strongly, less active with collodion. With short exposure there is a minimum at D $\frac{1}{2}$ E and a band from D to A (maximum D $\frac{1}{2}$ C), with long exposure there is a closed band from a to beyond H, but the dye makes the plates spotty. Dianilgranat B and G (M. L. Br.) is a weak sensitiser; it acts with prolonged exposure equally from F to beyond B. Plutoschwarz P G (By.) sensitises vigorously for red; the action extends from a to beyond D. Neutralblau 2 R (M. R. Br.), sensitising band from C to $\frac{2}{3}$ D, maximum C $\frac{1}{2}$ D; a second dye, Neutralblau R-giyes a narrow band from C to D. Alizarin Astrol B (By.), patented powder, vigorous band from B to C, with long exposure, extending beyond a, also a second line like band at C $\frac{2}{3}$ D. Brillantwollblau (By.), band from B to C $\frac{1}{2}$ D weak. Azosäureviolett B A L (By.) patented, band from C to C $\frac{1}{2}$ D weak. Kristallviolett P (By.), vigorous band from B to D $\frac{1}{2}$ E; maximum C $\frac{1}{2}$ with long exposure. Halbwollschwarz LS (By.) gives with long exposure a band in the red that reaches from B and fades before D. Chromotropblau A (M. L. Br.) acts

only with long exposure, and gives a band from E $\frac{1}{2}$ D to maximum at D. The band reaches with collodion emulsion from where it falls sharply off, to E. The maximum lies at D 1-5 W G and W B of this dye also sensitise. Rhodulinreinblau B (By.) gives a sharply limited band from B to C; the addition of silver nitrate to the bath considerably increases the vigour of the band. With equal exposure, it only acts slightly on collodion. Wollehtblau R L (By.) undecided faint band with maximum at E. Echt Dunkelblau R extra (M. L. Br.) sharp vigorous band from C to C $\frac{1}{2}$ D. Thiogenkohlschwarz, indistinct faint band at a-B.

The following dyes neither sensitise nor cause fog, nor greatly reduce the blue sensitiveness of the plate:—Anthracenrot (M. L. Br.); azophloxin 2 G (By.); azosäureblau 3 B, Konz. a (M. L. Br.); benzobraun und benzoechtgelb (By.); carminogen und chromoglaucin N M in paste; Dianildunkelgrün L (M. L. Br.); dianiltiefschwarz B T and T konz. (M. L. Br.); echtazogranatbas (By.); karbonschwarz (M. L. Br.); kaschmirblau F G extra (M. L. Br.); kaschmirschwarz T N (M. L. Br.); kategrünbraunschwarz (By.); lanoglaucin N paste patent (M. L. Br.); melanogenblau B (M. L. Br.); metanilrot 3 B, naphthylaminschwarz 4 B and 4 B K (By.); neuäthylblau RS and BS (M. L. Br.) (these dyes give fog even in weak dilution); orange R O (By.); pigmentechtgelb (M. L. Br.); rhodulinblau G G extra (By.); säurealizarinblau S N (M. L. Br.); säurealizarinrot G; säurealizarinschwarz S N P (M. L. Br.); säureschwarz 4 B L and L D (By.); sulfocyaninschwarz B (By.); sulfongelb R and 5 G (M. L. Br.); thiogen dyes (M. L. Br.); thiogenbraun G, G G, and G R; thiogendunkelblau B; thiogendiamantschwarz B and V; thiogengelb G and G G; thiogenorange G G, R G, and R R; thiogenschwarz 4 B konz. and M konz.; thiogenviolett and thiogenviolett B all cause fog and lower the blue sensitiveness, even when used very dilute; wollehtblau R L; wolldruckschwarz N B; wollscharlach 4 R and 4 R (M. L. Br.).

FIRES FROM MOVING-PICTURE EXHIBITIONS.

[Abstracted from the "Scientific American."]

The danger attending the use of moving-picture apparatus is due to the highly inflammable character of the celluloid film bearing the pictures and to the intense heat produced where the light is condensed upon the film. This heat is sufficient to ignite the film at the projection aperture if the light is allowed to rest continuously upon one portion of the film for a few seconds, but when the machine is in operation the film of course travels so rapidly across the projection aperture that the heat is without effect upon the film. The projection aperture, therefore, is the point at which the film is most apt to take fire, and in almost every instance the ignition takes place because a portion of the film is held stationary at the projection aperture for a time.

Contributory Causes.

This may be brought about in various ways. The film may break below the projection aperture; the feed mechanism may become jammed and inoperative; it may lose its hold on the film; the crank may become loose on the shaft of the feed mechanism so that its turning will not feed the film forward; a small fragment may be torn off the film and lodge in the projection aperture where it will be exposed to the full heating effect of the light; or the operator may stop turning the crank of the film feed mechanism for any one of a variety of reasons. He may become faint or giddy

from the heat or from escaping gas; his attention may be suddenly distracted and he may forget to keep the film feed mechanism in motion; or he may stop the feed of the film intentionally and neglect to cut off the light.

Preventive Measures.

Fires have resulted more than once from each of the foregoing causes, and it is practically impossible to construct moving-picture apparatus in such a way as to prevent the film from occasionally taking fire at the projection aperture. It is possible, however, to prevent serious consequences from the ignition of the film at this point, and this may be done by simply preventing the fire from following the film from the projection aperture to the reels upon which the film is wound. Ordinarily, these reels have from eight hundred to twelve hundred feet of film wound on them, consequently, if a flame reaches either of these reels the fire that results is so large, so hot and so difficult to extinguish that great damage to the building is almost certain to result, to say nothing of the panic that is always caused when a flame of any size breaks out in a place of public entertainment. If, however, the film burns only at the projection aperture, the flame will be small and do no damage.

Limiting the Fire Area.

To limit any fire that may occur from a moving-picture exhibition to a few inches of the film, it is only necessary to inclose both the

film supply reel and the take-up reel in fire-proof chambers and to provide valves leading into said chambers through which the film can pass freely while the film feed mechanism is in operation, but which will close instantly when the film feed mechanism ceases to operate or the tension upon the film is relaxed. If the film supply reel and take-up reel are inclosed in such fireproof chambers or magazines, the ignition of the film at the projecting aperture is a matter of very little consequence, as the burning of the film at that point immediately causes a reduction of the tension on the film and permits the valves through which the film passes into the magazines to close and so prevent absolutely the passage of the flame into the magazines. Properly constructed magazines for the film supply reel and take-up reel can be applied at very small cost to any moving-picture machine, and if the machine is equipped with such magazines it may even be overturned without causing any serious damage.

Alternative Methods of Prevention.

Other methods of preventing flames at the projection aperture from reaching the reels of film have been proposed, such as a non-inflammable plate of considerable size arranged above the projection aperture and extending rearward and to the sides for a considerable distance. Such a plate will sometimes prevent a flame at the projection aperture from reaching the film on the supply reel, but it is by no means as certain in its action as the magazines already mentioned, for the film above the plate is fully exposed, and if the flame rises above the edge of the plate it may strike the exposed

film and set fire to the entire reel. Another device which has been proposed to prevent the transmission of a flame from the projection aperture to the film reels consists of a pair of flat tubes or guides extending above and below the projection aperture and made of non-inflammable material, the idea being that in the small space afforded by these guides for the passage of the film a flame will be extinguished. As a rule, this device operates successfully, but as the reels themselves are exposed, a flame flaring up suddenly at the projection aperture may reach one of the film reels in spite of the guides.

English v. American Methods.

A plan of preventing fires from the use of moving-picture apparatus that has been adopted in England to a considerable extent is to inclose the entire apparatus in a fireproof box large enough to contain the operator also and to lock the operator in during the exhibition. This plan has the merit of making operators careful, but many grounds of objection to it are obvious, and American operators of moving-picture apparatus are unwilling to be locked in such a box while giving an exhibition.

Considered from all points of view, the most satisfactory and thoroughly reliable means for rendering moving-picture apparatus safe is a fireproof magazine for the film supply reel and a similar magazine for the take-up reel. Such magazines answer all the requirements and have the advantage of being readily portable and of being easy to apply to any standard moving-picture machine.

BAXTER MORTON.

ANOTHER LETTER TO A MIDDLE-CLASS PROFESSIONAL. THE QUESTION OF MOUNTS.

DEAR J.—In my last letter, talking of backgrounds (see *BRITISH JOURNAL OF PHOTOGRAPHY*, August 4, 1905), it was suggested that the general "get-up" of a print had much to do with the "common appearance" apparent when viewing an otherwise good work. The question was, however, shelved for a future communication.

Now mounts, as the amateurs have discovered, have a most important bearing on the finished photograph, and this point has to be borne in mind when you are making out your mount order.

What, then, are the underlying principles of a good mount? Of course, I have nothing to say here on the scientific question of purity.

Firstly, as with backgrounds, subordination to the chief feature—in this case the print—and, secondly, unobtrusiveness combined with efficient carrying out of its duties of properly enhancing the print. In other words, the mount has not to be seen before the print, the first impression should come from the photograph.

Arriving, then, at this conclusion, the whole matter can be summed up with one word, "simplicity."

The colour of the mounts should, perhaps, first claim your attention. You cannot, of course, have a different coloured mount to suit each print, neither is it possible in most studios to combine colours and to build up composite mounts used by the leading amateurs. It is also not worth while, for I know from experience that these mounts do not take with the public. Placing this method aside then, it is obvious that we must have either a set of one colour which will suit all prints made (white), or a set of two or three colours which by their negative tones will suit a variety of prints. I can imagine you preparing to ask: "What colours, then, should I choose?" This will depend in every case on the processes you work. What colours do you want that will be most useful for these varying needs?

The white mount, in spite of all the tirades levelled at it, continues to be the favourite of the public, and is generally used by all

photographers. Of course, it is an undoubted fact that the glare of the light reflected from the white surface seriously detracts from the portrait, and does not "show-up," to use the public phrase, the print so well as the dark-toned mounts, but, nevertheless, all arguments to the contrary notwithstanding, the public insist that the reverse is the case. As you are in business for profit and not pleasure, it is not advisable to run counter to the public belief. Moreover, with judicious arrangement of plate-mark, names, and proportions of mount, this kind of board can be made to look very stylish, and certainly not old-fashioned. You must therefore have a full stock of white mounts, not only because they are demanded, but because any colour and description of print can be mounted thereon without violently assailing any canons of taste.

Mounting schemes may be classed as contrasting or harmonising. The latter method of mounting in harmony is, I think, the more generally useful, and more successful as a seller than the contrasting method. This latter is useful at times to attract attention, and, if prints are carefully chosen, will look very brilliant and attractive; but, as I said above, you will find mounting in harmony—which, to give you a broad definition, is to use a mount of same colour or approximate to same colour of print—is much the best for artistic and business reasons; for, to repeat, "it is essential that a stock of mounts should suit, or, at any rate, not detract from a very great variety of prints." It must be borne in mind when weighing the pros and cons of harmony or contrast that, as a general rule, a print that is to look well on a mount of a colour to contrast with its own prevailing tone must be itself snappy and brilliant. In all probability, therefore, your delicate prints, or those somewhat flat and dull, will be overpowered on a contrasting mount; whereas a mount of approximately the same tone as a print would enhance and aid the print.

Our first consideration, then, will be harmonious mounting schemes.

Starting, as before, with grey-toned prints, it is obvious that we have the whole gamut of greys between white and black, as well as those colours, to select from. The first has been discussed, and the latter does not sell, so the greys remain.

The exact tone will, of course, depend greatly on your individual taste. As a rule, the public prefer the light to the darker tints. The latter, however, makes a good set-off to the white mounts, which the lighter tones somewhat approximate. A C.C. print, gold and platinum tones, does not look amiss, or a dark-grey with the slightest tinge of blue—some makers count grey as what I mean.

I will say no more about grey prints here, for no contrasty mounting is permissible—at any rate in business—with this cold tone, and I would particularly warn you against using a positive coloured mount with a negative-coloured print such as platinum. The result is almost bound to be failure. As an illustration, let me point out the cheap and common appearance given to work by some of the best firms when a grey print is mounted on a green board—a breach of taste very frequent a year or two ago, when the green mount was extensively used. The combination is bound to jar in all but exceptional circumstances.

Red prints would obviously look bad on a similarly coloured mount, but a mount approximating to that colour—such as warm brown or cream—will do, for cream as it gets darker is buff, and buff is decidedly brown. Green prints, when such are done, should usually be mounted on non-committal white, though some green carbons I mounted on dark green mounts looked better than any other green prints I have yet seen.

The discussion of mounts for contrasting schemes is, you will observe, much narrowed down by the exclusion of grey prints, and mounts for warm-toned pictures need only be discussed. The only colour very generally used is green, and if of a dark green, brown prints, and occasionally Bartolozzi red, look well; but the prints must suit, and should preferably be printed solid.

Cream mounts may be considered by some as a contrasting tint, though I spoke to you about it as a harmonising colour. As it is, a beautiful and extremely useful colour I will extend my letter a little and find time to say more about it. The actual tone should be a very deep cream—almost buff, not the dirty white that usually passes for a cream in traveller's samples. The colour you want is that of vellum. These mounts suit admirably sepias and browns of all descriptions, warm black, and are the mounts par excellence for the difficult red carbon. In fact, they will take all the warm tones usually used. Not only this, but they keep their colour in a case, and are not so easily soiled as white.

I do not know that the popular paper mounts require any special remark. Either the imitation hand-made paper or the Japanese vellum mounts are good. The latter have the same advantages and same restrictions as the cream mounts already written about. It is advisable to see that you get a thick sample of the vellum—there are many cheap and bad imitations on the market, but the best is, in the end, the cheapest. These mounts are somewhat difficult to mount upon, for it goes without saying that the prints must be mounted dry.

This letter is getting longer than expected, but I find that I have only at present discussed the vital question of colour, putting aside matters that, though of not such great weight, make all the difference between a good and an extremely good mount. To enumerate outside size of board, thickness of ditto, position of space to surround print, type of border—whether plate-mark ruling or what-not, edges whether plain cut-bevelled or colour-bevelled, and position for name and address—I hope at some future date to write you a letter on these points. At present I must be content to recapitulate—the following being in order of utility—those

I advise you to stock. If you can only afford one set, get the first colour; if only two, get the first two, and so on:—

White—for all prints.
 Cream—for all warm-toned prints.
 Grey—for all grey or black printing paper.
 Brown—for all shades of brown.
 Green—for brown, green, and red prints.

Just a last word, when ordering do get sets—i.e. some of each shape you use, rather than getting oddments of the various shapes at different times, for if you get them at one time they are certain to be uniform, and will look so in the show cases. Moreover, they will keep the same tone even when they fade slightly, for all mounts are bound to change colour a shade or two. This makes the appearance much better than when after a few days' exposure you find your cases contain half a dozen different tints.—
 Yours,
 STUDIOUS.

TONING BROMIDES WITH LEAD CHROMATE.

THE following method of obtaining yellow, orange, and green tones on bromide paper, whilst not new, may be of interest now that the toning of bromides is so much to the fore. It is, in fact, a revival, with modifications, of Eder and Toth's process of lead intensification for collodion negatives. It has been revived once or twice, and the main objection to it is the extreme difficulty of obtaining pure whites. Possibly, however, by following the directions carefully this defect may be avoided. Professor Namias is the author of this note, which appears in "Das Atelier des Photographen."

Two stock solutions are required:—

1. Potassium ferricyanide	8 g.
Water	100 ccs.
2. Lead nitrate	8 g.
Water	100 ccs.

Just before use the solutions are mixed in equal parts, and if there is any cloudiness the mixture should be filtered.

We may possibly interpolate here the remark that it is better not to keep the ferricyanide as a stock solution, but to mix it fresh as wanted, and the crystals should be rinsed before being dissolved.

The print, which must, of course, be quite free from hypo, or, if dried, must be soaked in water till thoroughly wet, is immersed in the mixture till thoroughly bleached, and then well washed till every trace of yellowness has disappeared. Now it must be immersed in a 1 per cent. solution of potassium bichromate, and the image will appear yellow. A thorough washing must follow, and then the print must be treated with a $\frac{1}{2}$ per cent. solution of sulphuric acid, which clears the image up, and converts some of the lead chromate into sulphate.

The chemical reactions which take place in this process are as follows, and they are given by the author, as it is obvious that, knowing the composition of the image, a long gamut of colours may be run through by playing on the formation of other coloured deposits by the use of various metals. The mixture of ferricyanide and lead converts the silver of the image into ferrocyanide of silver and ferrocyanide of lead. By treating with bichromate the ferrocyanide of lead is converted into lead chromate, whilst the silver ferrocyanide remains unchanged.

If, instead of the second treatment with bichromate alone, a mixture of bichromate, neutralised with ammonia, and potassium iodide be used, silver iodide and lead chromate are formed, and the former considerably increases the intensity of the image. The pictures thus obtained are yellow, and of great vigour.

If, instead of neutralising the bichromate of potash with ammonia, about $\frac{1}{2}$ per cent. of ferric chloride is added, blue ferrocyanide of iron is formed with the lead chromate, and by the combination of

the two colours an intense green tone is produced. Professor Namias states that this green can be obtained in no other way such intensity and stability, as it will stand a long exposure to sun and air.

The colour thus obtained is a bluish green, but it may be altered will by merely placing the print in a $\frac{1}{4}$ per cent. solution of monia or carbonate of soda, which decomposes the blue without on the yellow lead chromate, and a yellowish green is formed according to the length of its action.

With the bichromate solution some cupric chloride be added, an orange print is the result, as lead chromate and copper ferrioxide are formed. By treating this image with acid ferric chloride in weak solution the colour may be altered.

Whilst applied by Professor Namias to bromide prints, it is obvious the process is equally applicable to transparencies of all kinds.

THE CAPE TOWN EXHIBITION.

In our recent issue we made a preliminary announcement concerning the International Photographic Exhibition to be held at Cape Town, February next, under the auspices of the Cape Town Photographic Society. The prospectus of the exhibition is now to hand, and we give herewith particulars for the benefit of intending exhibitors in this country, who must bear in mind that three weeks is average time taken for letters or parcels to reach South Africa from London. As previously mentioned, the new City Hall, Cape Town, has been secured for the show, and we are enabled to herewith a representation of this fine building. This hall

The City Hall, Cape Town.

is also the meeting place of the British Association during its visit to South Africa this week. Exhibitors can, therefore, depend that every consideration will be extended to their exhibits, and that they will be displayed to full advantage. The judges will be:—Pictorial Classes—Mr. R. H. Whale (artist and technical instructor, Government School of Art), Rev. Mr. Hall, and Mr. A. J. Taylor. Genre and Figure Studies—Messrs. G. Crosland Robinson (art master, Government School of Art) and Diploma of Honour, Dresden Academy), J. J. Bissett, and Mr. Watson. Scientific and Technical—Dr. R. Marloth and Messrs. F. Fripp and W. Richmond. The International and open sections will include the following classes:—1, Landscapes; 2, seascapes; 3, architecture; 4, genre and figure studies; 5, still life; 6, lantern slides, subject (sets of three); 7, stereoscopic transparencies (sets of three); 8, stereoscopic paper prints (sets of three). A silver medal

is offered in each class in this section. An open section is also devoted to scientific and technical photography, and its application to processes of reproduction. Medals will be awarded at the discretion of the judges.

The society's gold medal will be awarded (in lieu of any other medal) for the most artistic picture, irrespective of class or subject, such picture to become the property of the Cape Town Photographic Society.

The conditions of entry are similar to those usually adopted by English exhibitions. An entry fee of 1s. is charged for each exhibit, and pictures from other parts than South Africa need not be framed, but must be mounted. The rules and recommendations of the "Conference of Judges," as published in the Photographic Red Book for 1905 will be adhered to.

All entry forms and exhibits sent by post must reach the secretary (Mr. A. J. Fuller, P. O. Box 470, Cape Town) on or before January 13. Cape Town exhibits and other exhibits forwarded by other means than by post, must be addressed to the Secretary (Mr. A. J. Fuller) at the City Hall, Cape Town, on or before January 13, 1906. The exhibition opens on February 3, 1906.

ACID FIXING IN EMERGENCY.

An acid fixing-bath has come to be considered a necessity for the successful working of gaslight papers on account of the extreme readiness with which these papers may be stained. E. A. Turner, in the current number of "The Photo Miniature," says: "Even with an acid bath, the prints must be quickly covered with the hypo solution and must be kept moving for the first few seconds. For fixing plates and films, while the acid bath is not a necessity, it is much superior to the ordinary hypo, especially in warm weather when stains are likely to occur, and when the hardening produced by an acid alum bath is an important advantage. For use at home most of the usual formulæ for acid fixing-baths are all that could be desired. But for the tourist it is desirable to avoid weighing, and to use dry, readily obtainable chemicals wherever possible, as liquids are not only bothersome, but may do considerable damage if a bottle should become broken. For such use the following bath is excellent—Warm water, 1 pint; anhydrous sulphite soda, $\frac{1}{4}$ level teaspoonful; alum, 1 level teaspoonful; cream of tartar, 1 rounded teaspoonful. When dissolved, add: Hypo (measured in graduate), 4 oz. Stir and it will quickly dissolve.

This formula should produce a perfectly clear acid fixing-bath, suitable either for gaslight prints or for plates or films. By using warm water, the resulting solution, after dissolving the hypo, is of ordinary temperature and ready for immediate use. If water of ordinary temperature is used the hypo will cool it so much that the solution will be extremely cold, will fix slowly, and be likely to cause blisters. By measuring the chemicals, instead of weighing, considerable time is saved, and the accuracy is sufficient for every purpose.

Some workers prefer to leave out the alum in a fixing-bath used for plates and films, as the hardening produced by the alum makes the gelatine of the negative hard and impermeable, and such negatives are much more difficult to intensify or reduce than negatives which have not been thus hardened.

THE Princess of Wales has honoured Messrs. Speaight, the child photographers, of 157, New Bond Street, by accepting from them for the use of little Prince John, the first copy of their new edition of "Baby's Album."

THE summer number of the "Practical Photographer" deals with Photography of the Sea. The Rev. F. C. Lambert deals with "The Hand Camera at the Seaside," and "River and Lakeland Photography" are also dealt with. Marine photography and the pictorial work of F. J. Mortimer, F.R.P.S., forms the subject of the editorial.

Photo-Mechanical Notes.

The Dots of Albumen and Enamel Prints.

SOME years ago half-tone negatives were nearly always printed by the albumen process. Albumen was a fairly simple and reliable method, but had the serious drawback of giving a ragged, unfinished appearance to the half-tone plate. This unsatisfactory appearance of the picture was caused by the inking and dusting up of the plate, giving ragged edges to the dots. On

Fig. 1.—Photo-micrograph of etched half-tone plate printed by albumen method.

this account bitumen-printing was adopted for the finest work, but this method was extremely slow and uncertain. The advent of the enamel process changed all this, as clean, smooth dots were obtained with comparatively little trouble.

Fig. 2.—Photo-micrograph of etched half-tone plate printed in enamel.

A comparison under the microscope shows in a very interesting manner the superiority of the enamel over the albumen method of printing.

In the accompanying illustration the improvement in sharp-

ness and roundness of the enamel over the albumen dot is very clearly demonstrated. The first photograph is from an albumen printed plate. The dots are ragged at the edges—this is partly due to the plate having been rolled up with litho ink and also to the subsequent dusting-up with dragons' blood.

Fig. 2 is from an enamel print, and in this case the dots are very much rounder and sharper; though, of course, the microscope reveals a slight unevenness of the edges. These prints show in the enlarged dots the reason why the enamel is superior to the albumen half-tone plate.

The same negative was used for both prints, and the plate was only etched sufficiently to show the dots clearly when the resist was removed.

J. I. Pigg, F.R.P.S.

Patent News.

The following applications for patents were made between July 3 and August 5:—

OPTICAL LANTERNS.—No. 15,607. Improvements in or connected with optical lanterns. John Ambrose Sprason, 48, Corporation Street, Birmingham.

TRIPOD HOLDER.—No. 15,624. Tripod holder. George Felix Shilk, 23, Fleet Street, Swindon, Wilts.

DAYLIGHT LOADING.—No. 15,695. Daylight loading wrapper for photographic plates. Albert Hawkins Clark, Ferncliffe, Pembrokehire.

LENSES.—No. 15,732. Improvement in lenses. The firm Rathenow Optische Industrie-Anstalt vormals Emil Busch, Act. Ge. 37, Chancery Lane, London. [Date applied for under Patents Act 1901, 13th April, 1905, being date of application in Germany.]

DARKSLIDES.—No. 15,958. Improvements in and relating to means for carrying and exposing dry sensitive photographic plates or films in the camera. George Wishart, 96, Buchanan Street Glasgow.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

CHANGING APPARATUS.—No. 20,769, 1904. The patent is for a dark-slide or light-tight changing box which may be similar in external shape to an ordinary dark-slide, having at one side an exposure opening covered by a sliding panel or shutter and at the other side a detachable light-tight lid or cover. Within the said changing box a loose detachable partition preferably consisting of a piece of cardboard or other suitable material, is provided, that is capable of being bent into a shape that will impart to it a certain amount of resiliency, said partition constituting a combined guide and pressure piece for the films. This changing box is furnished with suitably arranged teeth or stop-pieces near the aforesaid outlet, opening or slit through which the manipulating tabs on the film protrude, said stop-pieces being adapted to engage with appropriately shaped openings in the said tabs when the latter have been withdrawn far enough to cause the exposed film to enter the space behind the resilient partition, thus affording a reliable stop for ensuring that the exposed film shall not be withdrawn too far and that they shall be withdrawn to the same or approximately the same extent. A further claim is for flexible films mounted on opaque backing paper or tabs for use with a film changing box. Benjamin Joseph Edwards Greylands, Castle Bar Park, Ealing.

CINEMATOGRAPH ADVERTISING.—No. 6,776, 1905. This patent relates to cinematographic advertising apparatus which consists of a series of illustrated panels arranged alongside a railway track or other road, in such a manner that an observer travelling rapidly past the apparatus, is given a view of an apparently animated object similarly to that produced before a stationary observer by a moving film in the cinematograph. A plate or wall is placed in front of the illustrated panels and parallel thereto, and there are slots in the said plate, which only allow one picture to be seen at once. An improved form is that in which the pictures are inclined so that an observer may see two different sets of pictures according to whether he sits with his back or face to the direction of travel. The pictures may also be transparencies and illuminated from behind. Albert Demierre, Bulle, Switzerland.

New Materials.

Pattern Premo Film Pack. Sold by Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

A new pattern of this handy camera accessory has been put on the market by Messrs. Kodak, Ltd. When the great utility and popularity of the film pack is taken into account we are surprised that an improvement which forms the chief feature of the new pattern has not been introduced sooner.

This improvement enables any exposure to be removed for development without disturbing the remainder of the films in the pack. The pack, as our readers are aware, includes twelve flat orthochromatic films, interleaved by and attached to black paper separators, by means of which the changing is effected. Hitherto, the first twelve films had to be exposed before the pack could be opened, and the exposures developed, but now, in the new pattern, a simple device the bottom part of the pack can be removed (the dark room, of course), and any film removed for separate development. After removing the film and closing the pack, the latter can be replaced in the camera or the adapter, and further exposures made on the remaining films. There is no difficulty in selecting the chosen films, as each is attached to its black paper backing, which is conspicuously numbered in red. These numbers appear white in the ruby light of the dark room, and are easily identified. This little addition to the film pack will undoubtedly increase its usefulness and popularity tenfold.

CATALOGUES AND TRADE NOTICES.

No. 2 of "Lizar's Magazine" is to hand. It is published by Lizards, of 71, Bold Street, Liverpool, and contains notices concerning the firm's goods, and other information.

WILFRED EMERY'S "Apek" Novelties are neatly listed in a small pamphlet, which will be sent on application to the Works, High Road, Cricklewood. Among Mr. Emery's specialties may be mentioned Apek S.T. papers and postcards, Apek P.O.P. and cards and slight papers, Apek hand and stand cameras, and all accessories. Notices for developing, enlarging, and printing on P.O.P. are also given.

A BEAUTIFULLY illustrated and well printed little booklet is the latest catalogue and price list of the Century Camera, made by the Century Camera Company, of Rochester, New York. Messrs. O. Sichel and Co., of 52, Bunhill Row, London, E.C., are the English agents for these popular cameras, which are priced to suit every purse. Photographers should write for a copy of the list.

A MOST complete list of tools and machines for picture-frame makers, including the latest and best inventions for picture-frame making,

mount cutting, etc., has been sent us by Mr. Henry Lawson, picture-frame manufacturer, of Pittenweena, Fifeshire, Scotland. Everything that the professional or amateur frame-maker wants will be found in this catalogue, which is well illustrated. A copy will be sent free on application.

New Books.

La Fotografia Senza Obiettivo. By Dr. L. Sassi.

I. Primi Passi in Fotografia. By Dr. L. Sassi. Published by Ulrico Hoepli. Milan.

The first of these little manuals deals with the subject of the "pinhole" or lenseless photography, and describes the making of the pinhole, and all its possible applications, such as interior and landscape work, copying full-size, and enlarging. Several instructive illustrations and diagrams are given and some useful tables.

The second manual is, as its title implies, "The First Steps in Photography," an elementary text book, and deals with the choice of apparatus and all the necessary operations for completing both negative and print, and the instructions are simple and not overloaded with a multiplicity of formulae, which are so bewildering to the beginner.

Special summer number of "The Studio," published at the offices of "The Studio," Leicester Square, London. Price 5s.

When the leading English magazine devoted to the fine and applied arts announced that its special summer number would deal with the erstwhile despised sister of the arts—photography—we were prepared to see something very special indeed. "The Studio" has long been noted for its excellent reproductions of works of art and its catholicity in respect to the graphic arts generally has secured for it a high place in the estimation of all pictorial workers.

This special number has now been published, and our anticipations, so far as the reproductions are concerned, are fully realised. Possibly at no time have photographs been reproduced with so much care and attention to the qualities of the originals as in the present case. In nearly every instance the colours and textures of the prints have been rendered in such a way that makes each plate (and there are 112 of them) as worthy of being separately cherished as the original print would have been. Whether the original prints would, in every case, have been altogether worthy of that attention would depend, of course, on individual taste. But the fact remains, the reproductions are excellent. We wish, however, that in a publication of distinction, such as this undoubtedly is, the literary matter was as good as the illustrations. A great opportunity appears to have been lost in not making more of the claims of modern pictorial photography. As it is, the letterpress is little beyond a more or less critical review of the pictures reproduced and a list of the workers, while the present condition and position of photography receive but scant consideration. Mr. Clive Holland (author of "Making and Faking Photographs") contributes the reviews of English, French, and Belgian work. Mr. Charles H. Caffin has a short essay on "The Development of Photography in the United States," Mr. A. Horsley Hinton deals with Pictorial Photography in Austria and Germany, and Dr. Enrico Thovey gives some notes on Artistic Photography in Italy. We can, nevertheless advise every pictorial photographer to secure a copy of the book while there is yet time, as it is a marvellously cheap production, considering its bulk and quality; and we feel sure that a great step towards the recognition of photography as a means for the making of pictures has been achieved by the publication of this specially illustrated number of "The Studio."

"**HERTFORD AND ITS SURROUNDINGS**" is the title of the 43rd volume of the useful series of little handbooks published by The Homeland Association, Ltd, 22, Bride Lane; Fleet Street, E.C. It is written by Mr. W. Graveson, of Hertford, and deals with the county town of Hertford, and the country along the Lea Valley between Hatfield and Broxbourne. Its associations with Charles Lamb and Isaac Walton render this country of general interest to readers. There is a chapter on Haileybury College, and an account of the Hertford branch of Christ's Hospital. The illustrations, forty-eight in number, are from photographs by Mr. Arthur V. Elspen, and the volume is provided with an excellent map of the district on the scale of one inch to the mile. It is published at 1s. paper cover, 2s. cloth bound, postage 3d.

A POSTCARD to the Town Clerk of Salisbury will procure a copy of the Salisbury Souvenir, a most elegantly printed little guide to this beautiful old cathedral town. The book is admirably illustrated from photographs.

No. 71 of the "Photo Miniature" has been published, and deals entirely with "Marine and Surf Photography." The work and methods of Mr. F. J. Mortimer, F.R.P.S., forms the bulk of the book, while a postscript in the shape of some notes by Mr. J. H. McCorkle, a well-known American marine photographer, adds further interest to the little volume. Thirty-six examples of Mr. Mortimer's work are reproduced, and two of Mr. McCorkle's. They are excellently printed.

News and Notes.

In the "Journal de Physique" for May, M. Adrien Guébard contributes a paper on photographic action, illustrated by curves showing the darkening due to development as a function of the time, and the superficial changes as a function of the sum of the causes producing them—as he calls it, the "photographic function." It is well known that the effects of greatly over-exposing a negative is to reverse the photographic action, sometimes producing a positive instead of negative impression. M. Guébard discusses the theory that the photographic function, after reaching its maximum and descending to a minimum, attains a second maximum, followed by a second minimum, and he describes experiments in support of this view.

THE Northern Photographic Exhibition.—The 6,000th visitor to the Northern Photographic Exhibition, at the Leeds City Art Gallery, arrived on Friday evening last in the person of Mr. F. W. Lawton, 17, Ashville Road, Cardigan Road, Leeds, who selected as his prize—awards are made to every thousandth visitor—Wm. Clayden's "Tagging Home." A lantern lecture illustrating "A Run to Norway" was given on Friday by Mr. Ingham Learoyd, president of the Halifax Camera Club, who showed nearly 150 excellent slides from his own negatives. The exhibition closed on Saturday last, and appears to have been very successful.

THE Camera in Western China.—The experiences of Mr. Alexander Hosie, British Consul-General at Chengtu, Central China during his recent journey from that place through Western China to the frontier of Tibet and back, form the subject of a Foreign Office report just issued, and make an exceptionally interesting narrative. Mr. Hosie made several ineffectual attempts to photograph the natives, the women being particularly picturesque. He says: "I was anxious to get a photograph of one of these maidens got up in all her finery and jewellery, but money was

powerless to make her look at my camera. She retreated into dark recesses of the house, and declined to reappear."

THE tenth annual athletic and cycling meeting of Hentschel's Athletic Club will be held at the London County Grounds, Bursage Road, Herne Hill, to-morrow (Saturday).

THE St. Louis Collection of Photographs.—The collection of pictures which represented British pictorial photography at the St. Louis Exposition has attracted much attention at the Leeds Municipal Galleries during the past few weeks. It is to be sent in entirety to an exhibition in Rochdale which opens in April next.

MR. T. BIRTLES, F.R.P.S., a well-known photographer of Warrington has just opened new premises and studios in place of old studio, which has been demolished to allow of Municipal improvements. The following description of the new buildings been sent us: "On entering from Sankey Street the visitor finds himself in a commodious and well-appointed reception-room picture gallery. At the end of this room is the entrance to studio, which in size can certainly be regarded as one of the finest in the country. Adjoining it are dressing-rooms fitted with every convenience. Underneath the studio are the dark-rooms, enlarging and printing rooms, all of the most up-to-date character. The space at the rear of the buildings will be specially arranged for photographing of groups, horses, and outdoor pictures generally."

SOUTHAMPTON CAMERA CLUB.—The members of this club met Monday evening last, at the Philharmonic Hall, Southampton. Mr. C. M. Cooper read a paper on "Micro-photography," and dealt fully with his subject. He specially discussed the difficulties of exposure, laying down the fact that, owing to the varying factors of light, colour values, and magnifications, exposure must necessarily be a matter of experience rather than of schedule. Mr. Cooper also read a paper on "Combination Printing."

THE Warwick Competitions.—The result of the July competition is as follows:—1st prize £10, G. R. Henderson, Esq., 162, Elliott Street, Hebburn-on-Tyne, "A Decorative Study"; Donation £5 to the Jarrow and District Camera Club; 2nd prize £5, H. Blagden, Esq., Camera Club, Charing Cross Road, London, W.C., "Competition in Meadow"; Donation £2 10s., to the Camera Club, London. Entries for the next competition must reach Warwick not later than August 15 next. Entry forms and particulars can be obtained from the Warwick Dry Plate Company, Warwick.

THE British Association inaugurated their visit to South Africa this week with a meeting of all the sections at Capetown. A grand reception was held on Wednesday night by the Mayor of Capetown at the City Hall, of which we give an illustration on another page. The members of the Association, possibly to the surprise of some of the natives, found on their arrival an offshoot from the main body flourishing on these distant shores, in the person of the "South African Association for the Advancement of Science," who have made arrangements to participate in the proceedings. The characteristics of the South African Association appear both energetic and business-like, for they have presented to the British Association a sum of £500, and guaranteed in addition to purchase 1,000 copies of the "Proceedings" published in connection with the visit. It is pleasing, as well as interesting to note that a large number of South African scientific men have arranged to read papers at the meetings.

SUMMONS as "Picture Postcard."—A Hemsworth woman declared on oath at Pontefract that the purport of a summons was not explained to her. She did not understand it. She thought it was a picture postcard, and she had it framed and hung in the house.

WE learn from an American contemporary of the death of Mr. John Carbutt, the pioneer maker of dry plates in America. Mr.

Carbutt died at his home, Germantown, Philadelphia, on July 26. In 1879 he made his first dry plates commercially in America, although he made dry plates for his own use in 1868 in Chicago, where he was actively engaged in photography. He was a chemist of marked ability, and to his efforts was due the introduction of the orthochromatic plate in America. Mr. Carbutt was an Englishman, and was born in Sheffield in 1832. He was the first president of the Photographers' Association of America, and did much to advance the interests of that organisation.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
1.....	Manchester Amat. Photo. Soc.	Ramble to Cartmel Priory.
1.....	Bowes Park and Dis. Ph. Soc.	Competition: Prints of Wheathampstead and Leigh-on-Sea Outings.
3.....	North Middlesex Photo. Soc. ...	Lecture: "A Variety Show." Mr. Harry Barnard.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday, August 24, at the White Swan, Tudor Street, E.C., Mr. T. E. Freshwater will show a set of Japanese coloured slides which have just arrived in this country.

Commercial & Legal Intelligence

WALTER TYLER, LIMITED.—Registered August 2. Capital, £10,000 in £1 shares. Object, to acquire the business of manufacturers of and dealers in optical and magic lanterns and slides carried on by W. C. Tyler at 48-50, Waterloo Road, S.E. No initial public issue. The first directors are W. C. Tyler, E. H. Bishop, and T. H. Palmer. Registered office: 48-50, Waterloo Road, S.E.

LETO PHOTO MATERIALS COMPANY (1905), LIMITED.—Registered August 2. Capital, £10,000 in £1 shares. Object, to acquire the business of a company of the same name incorporated in 1904. No initial public issue. The first directors are F. A. Zimmermann, R. A. J. Zimmermann, and F. W. T. Krohn (all permanent). Registered office: 3, Lloyd's Avenue, E.C.

ALLEGED SPY'S ACQUITTAL.—At Sheerness, on Saturday, Mr. Arthur Gill, on behalf of the Director of Public Prosecutions, announced that it was not proposed to proceed further with the charge against Franz Heinrich Losel, a German subject and a resident of the town, of photographing, or attempting to photograph, the new Ravelin battery. Counsel said the case had been reconsidered as a result of a search of defendant's premises, where the photograph found showed that the camera was not directed on the new battery. Defendant, however, was guilty of grave indiscretion in going on the property of the War Department with a camera, particularly as he was a foreign subject. Mr. Booth Hearn, defendant's solicitor, said there was no evidence of any kind to show that Losel was there with any criminal intention. He was there with the legitimate object of photographing the town. The magistrate agreed with Mr. Gill as to defendant's grave indiscretion, and said he considered the proceedings absolutely right and proper. Defendant must be more careful in future. The charge was then dismissed.

Correspondence.

"WHO TOOK THE PHOTOGRAPH?"

To the Editors.

Gentlemen,—My attention has been drawn to a paragraph in your last issue, headed as above. In it the writer is anxious for the name of the "firm" who took a photograph of a child's cot in the Northern Hospital, Manchester, which picture has been offered to and accepted by the Queen. As the author of the photograph in question, I am a little at a loss to know what Manchester paper or papers has supplied your correspondent with the facts on which he bases his little article. The only paper, so far as I am aware, which noticed the "event," was the "Manchester Guardian," of August 2nd. I enclose the cutting, from which you will see that the authorship of the photograph is plainly ascribed to me. I am not a "firm," but only an amateur, and a member of the local amateur society. Incidentally, I should like to add that the information contributed to the "Guardian" was not sent by me, or with my desire or connivance, either direct or indirect. As a member of the medical profession, I am inclined to deprecate such references in the ordinary daily papers, as savouring too much of self-advertisement. This does not, of course, apply in the case of a technical paper like yours, so that I may add that I took nine negatives before securing a fairly satisfactory result, and that an enlargement from half to full plate was made for me by Messrs. Chapman, of this city.—I am, yours, etc.

R. W. WALSH.

Ebor Lodge, 381, Bury New Road, Manchester, August 14, 1905.

[We are obliged to Dr. Walsh for his information. The cutting he encloses certainly gives the authorship of the photograph in question and other particulars. We have not the newspaper by us in which we observed a reference to the event, but it certainly contained no mention of the photographer who obtained the photograph.—Eds., B.J.P.]

THE P.C.U. AND THE CROOKE-IRVING CASE.

To the Editors.

Gentlemen,—I am desired by my committee to send you the enclosed copy of letter sent to the Editor of the "Daily Chronicle," in reply to a report of an interview with Mr. Clement Shorter, which appeared in that journal of July 8th, of which I also enclose a copy.—Yours faithfully,

HENRY GOWER,

Secretary, Photographic Copyright Union,

23, Soho Square, London, W., 9th August, 1905.

[Copy.]

To the Editor of the "Daily Chronicle."

Dear Sir,—At the monthly meeting of the Committee of the Photographic Copyright Union, attention was called to the report of an interview with Mr. Clement Shorter, of the "Sphere," on the recent action for infringement of the copyright in a photograph of Sir Henry Irving, brought by Mr. Crooke, of Edinburgh, against the Scots Pictorial Publishing Company; and as there are certain misleading statements therein prejudicial to photographers, I am desired by my committee to ask your courtesy to insert this reply. That the suggestion that public personages should be photographed only upon the usual terms charged to private individuals, the committee feel sure would be welcomed by the majority of photographers. My committee cannot agree with Mr. Shorter, "that the

whole of this copyright law is shadowy," and would remind him that copyright in a photograph is property, which is the basis of all copyright law.

He also states that the "history of a photograph is coincident with the process block," which is quite wrong, and that a photograph only became valuable on its introduction. The real facts are that a very large business has been done in the publication of photographs of "public personages" since the early fifties, as can be evidenced by the well-known publishing firm of Marion and Co., of Soho Square, who, in the course of their business transactions with one firm of photographers alone, paid no less a sum than £27,000 for photographs for resale to the trade, and large amounts to several others, and their stock would be two million cartes-de-visite and one million cabinets at a time to meet the demand. This would represent considerable business to photographers, which has been practically swept away since the introduction of the process block; and as unauthorised use of photographs was in many instances made by the Illustrated Press, photographers found it necessary to protect their interests by the formation of the Photographic Copyright Union, who have framed a minimum scale of charges for the granting of licences for the reproduction of their copyrights.

This is the position of photographers, which provokes Mr. Shorter to say "that they have become little short of robbers."—Yours truly,

For the Committee of the Photographic Copyright Union,
HENRY GOWER, Secretary.

[We have already commented on the "Daily Chronicle" interview with Mr. Clement Shorter, in our issue for July 21st.—Eds., B.J.P.]

EXPOSURE TABLES.

To the Editors.

Gentlemen,—Having recently had occasion to take a short voyage in a sailing vessel up the East Coast, I made the most of my opportunities to secure some photographs of the sea and shipping en route. I used a folding camera and plates of medium speed, and knowing that the light would be very bright, stopped my lens down to $f/11$ or $f/16$. The shutter (between lens) I worked at its highest speed, which was marked 1-100.

All my negatives have turned out failures from over-exposure, and I have come to the conclusion that not only are exposure meters somewhat unreliable for work of this sort, but the exposure tables as published are also incorrect.

In most exposure tables August light is given as being the same as that in either April or May. My recent experience shows me that it is as bright and actinic during the first half of August as at any other time of year. I have photographed at sea during May in the same locality as that which I have just visited, and I found then that the exposures I have mentioned above were none too much to secure full exposure. There seems to be an extra brilliancy and glare about August light when the sun is shining, that is lacking in April or May, or even June. I think therefore that July and August should be bracketed equal so far as the power of the light is concerned.

Another point I should like to raise in connection with exposure tables is that the light at 9 a.m. is usually marked as being equal to that at 3 p.m., the reason being, I suppose, that the compilers of these tables have decided that theoretically the light three hours before noon would be the same as that three hours after noon. During the summer months I have always found, and doubtless other practical workers have also found, that the light at 3 p.m. is generally much more actinic than at 9 a.m.

I mentioned exposure meters as being rather unreliable for subjects such as the sea when flooded with bright summer light, as my experience with them has been that they do not indicate a brief enough

exposure for the purpose, and to rely on them usually results over-exposure.—Yours faithfully,

EDWARD G. MARCHANT.

Margate, August 14.

[We have commented on our correspondent's letter in another part of the Journal.—Eds. B.J.P.]

BACKGROUNDS.

To the Editors.

Gentlemen,—While every encouragement should be given by the leading photographic paper in this country to industries and handicrafts carried on in these islands, whether by Englishmen or foreigners (who, by the way, have to pay their rates and taxes), yet a statement, as that which appeared with regard to individual broad-treated backgrounds, not only tends to strengthen the prejudice against home productions, and a quite unfounded belief in the superiority of Uncle Sam's artistic abilities, but they are a direct perversion of the actual state of things.

It is obvious to everybody with an artistic turn of mind that America (for this was the producing country hinted at in your columns) is not an artistic country; they send their aspiring geniuses to Paris, London, Munich, or Berlin and Vienna, where they mostly remain. As for that peculiar art of background painting, as practised by several prominent "artists" over there and boomed over here with the big drum, the less we say about it the better, for it is a poor testimony to the standard of artistic education (of the public at least), to be photographed with those impossible and curious: laboured clouds and scrolls in oriental barbaric splendour, in mid-air suspended, curtains and pillars. A recently issued American catalogue was full of those "creations."

The writer of this, along with some other artists, for years has made strenuous efforts to bring about a better understanding for the refined styles of English and Continental art, past and present, which are quite at their door, but which the greater part of the photographic profession fail to grasp. So far, only a small cultured minority have availed themselves of the opportunity to have their own ideas carried out; individual treatment as regards the ever-changing conditions of light, etc., should be one of the first considerations in a background, and this can only be done effectively by a matured cultured artist, who not only possesses a full knowledge of the artistic possibilities of photography, but also of its limitations, and who also commands a quick *recherché* technique (the old Italian tempera being the most beautiful and expressive for rendering soft "al fresco" effects).

For this purpose no one need to send his orders out of the country, and pay 50 per cent. more and get disappointed about the result.

London is by common consent amongst artists (French, German, English, or Italian) the most important, refined, international art-centre in the world. More elbow to London artists and English photo-industrial enterprise generally!—Yours faithfully,

Fitzroy Square, London, W.

EMILE NIEBES.

[Mr. Niebes sends for our inspection some specimen photographs of American backgrounds, and also some of his own commercial work, but as he has not made it quite clear in every case which are the productions of "Uncle Sam," and which are the examples of "recherché technique," we can make no comparisons for the purpose of substantiating his statements. We would, however, draw our correspondent's attention to the original remarks made by our contributor "Studiosus" (see p. 612, ante). He says: "Perhaps the best grounds for general use are the plain graded ones, and these have the undoubted advantage, as the English background painter can paint them without any great blunder, and you are almost sure to get them good. . . . It is against cheap scenic grounds that my preliminary tirade was directed."—Eds. B.J.P.]

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

J. and E. Grosvenor, 2, Belvoir Terrace, Cowleigh Road, Malvern, Worcester. Photograph of Malvern Foresters' Jubilee Dinner, July 31st, 1905, at Drill Hall, Malvern.

J. Smith, 281, Lord Street, Southport. Photograph of Illuminations; Municipal Gardens, Southport.

Edm. 35, Taylor Street, Woolwich. Photograph of J. Ashcroft, Woolwich Arsenal Football Club Goalkeeper.

Wm. H. Azulay, 48, Castle Avenue, Rochester, Kent. Photograph of the King and Duke of Connaught in carriage, taken at Chatham, July 26, 1905.

R. Hogben, 25, Guildhall Street, Folkestone. Photograph of group, "General" Booth and Mr. and Mrs. Spurgeon at "The Rivulet," Radnor Park Avenue, Folkestone.

COPYRIGHT.—We have received from a customer several books containing engravings to reproduce, all published before 1870, which he says do not come under the Copyright Act. He further states that any plate issued with a book prior to 1863 is perfectly free, i.e., open to any one to reproduce the plate, although the letterpress is still subject to the author's life. Can you confirm or otherwise? The point is: Can we safely reproduce for him plates prior to 1863 (two) or ditto 1870.—**REPRODUCER.**

1. We are not sure that pictures produced prior to the Copyright Act of 1862 may not be covered by the Act of 1842. 2. With regard to the 1870 pictures, they will certainly be copyright if the artist is still alive, or if he has not been dead seven years.

HUMPHREY.—Would you kindly inform me the cause of this mottled appearance in the enclosed prints?

The mottled, or rather granular, appearance seems to be due to the prints being too heavily squeezed on to the plate while the gelatine was in a soft condition. Alum the prints after washing, and let them dry. Then wet them again and squeeze on to the plates. That will avoid the trouble. We do not answer correspondents by post.

RIGHT TO PUBLISH.—I took a gentleman's house in the country a short time ago, not for an order, but for my own pleasure, as I was walking across his park by a public footpath, on which I stood when taking negative. I now wish to know if I can print post cards from the same for sale, without asking permission of the owner of the house?—**PROFESSIONAL.**

If the photograph was taken from a public thoroughfare, we do not see that you can be prevented from publishing the picture. As a matter of courtesy, however, you might ask the owner of the house if he has an objection to the publication.

CHERRIE.—I would like your opinion on the following matter. Our establishment is closing for cleaning-down purposes, pro-

bably for a month. Can the assistants claim wages for that period or not, as they will not be working?

Certainly they can. The people are in your employ, and if you choose to suspend your business it is no affair of theirs. They must be paid their salaries.

ADDRESS WANTED.—Will you oblige with the address of the firm publishing A. Whiting's book on Retouching?—**CHIPPY.**

Messrs. Dawbarn and Ward, Farringdon Avenue, London, E.C.

COPYRIGHT.—Having purchased a negative from photographer, with sole right to reproduce picture post cards, etc., we find another printer has copied our view and published picture post cards. We have not yet copyrighted it. Can we compel all cards to be called in and destroyed and stop further sale, and claim damages for infringement before view was copyrighted. We are now copyrighting the view, as advised, and by permission of the photographer. Had we better treat the case from time of being copyrighted, or before. Do you consider we have a good case for damages.—**PRINTER.**

We doubt very much whether all cards can be called in and destroyed, as no action can be taken for an offence committed before registration. As soon as the copyright is registered, and it must be properly assigned by the photographer, then there would be good ground for action, and an action would lie for a penalty of not more than £10 for every copy sold, also forfeiture of all copies and negatives used in their production; and, in addition, by special action, damages may be claimed.

ORTHO.—We are obliged for your letter and negatives, but we have nothing to add to our previous answer. All the orthochromatic films on the market—and there are several—are, we believe, sensitised with erythrosine, and if you look through our advertisement pages you will find the addresses of the makers.

LENS FOR POST CARD WORK.—Will you please inform me what is the most suitable lens for post card work in streets and other confined places, to take the exact size of pictures. Also, are ordinary and backed plates better than the rapid ones for general outdoor view work.—**D. K.**

Any lens that will cover a $5\frac{1}{2} \times 3\frac{1}{2}$ plate will do, and any of the newer anastigmatic lens listed for a 5×4 plate, and of about 6 or 7 in. focus, would answer. The question of plates is to some extent a matter of personal opinion; but we should prefer the backed ordinary plates, as not only are they much easier to work, but there is also greater latitude in exposure.

CELLULOID VARNISH.—Please give formula for making a celluloid varnish, and also the name and address of a maker of sheet celluloid. **PHOTOGRAPHER.**

A standard formula is:—Celluloid, 7–10 grains; amyl acetate, 1 oz. The quantity of celluloid must be adjusted according to the thickness of the varnish required. Another excellent solvent is a mixture of equal parts of amyl acetate and acetone. Guiterman and Son, 33, Aldermanbury, London, E.C., are agents for sheet celluloid. If the celluloid is required merely to make varnish, it would be preferable to obtain scrap celluloid, which can be had from several makers who coat rollable film.

BROMIDE.—We believe the cards are developed with ferrous-oxalate, well fixed and washed and then toned in hypo 1 oz., hot distilled water 6 oz.; powdered alum 50 grains, when dissolved

add 25-30 minims of a 10 per cent. solution of silver nitrate. Heat the bath two or three times to 120-140 deg. Fahr., allowing to cool in between. The temperature of the bath at the time of using should be 100-120 deg. Fahr.

SKIN TROUBLES.—Would you kindly inform me whether "sodium hydrate" in the enclosed formula would cause the fingers to fester? Because two of us, in working the same, suffered afterwards, one by festering and myself in my fingers. All round the bottom of the nails appeared holes like pricks from an instrument. I should be much obliged if you would tell me if it is dangerous to use the hydrate and metol mixed?—G. F. BURRELL.

It is much more likely that the trouble is due to the action of metol; but no doubt this would be intensified by the caustic soda softening the skin. We would suggest abandonment of the metol and the use of adurol, or ortol. Many people can use metol without any harm, but others it attacks at once. In any case there is no need to use caustic soda, as equally fine results will be obtained by the use of an equivalent quantity of carbonate of soda.

A. COUTTHARD.—We are unable to give you any assistance, without seeing a negative or two, as we cannot possibly understand how an unexposed plate will fix, and not a developed one. Are you sure you have not fogged the plates and are making a mistake?

COPYRIGHT.—Will you favour me by kindly telling me if I can copyright a photograph, taken by my predecessor whose business I have acquired, or could my predecessor make them copyright himself, and thus prevent them being sold by outside people?—COPYRIGHT.

As your predecessor is the author of the picture, it must be registered in his name. He can then assign the copyright to you. This must be done in writing, and the assignment should bear a sixpenny stamp.

TONING SLIDES.—Could you kindly either give me a formulæ or recommend me a book on the toning of slides and films. I desire a green, but whites to be kept clear.—E. J. L.

There is no work, so far as we can recall which deals exclusively with the toning of slides. There are several methods of obtaining green tones, one is given on page 647. Another, using cobalt salts, was given in our issue for February 3, 1905, but the prints by this are not permanent. Another method is by using uranium, 10 per cent. solutions of (a) uranium nitrate, (b) ferric ammonium citrate, (c) potass ferricyanide, (d) nitric acid. For use mix (a) 1 vol., (b) 1 vol., (c) 2 vols., (d) 2 volumes, water to 40 volumes. Wash afterwards till the lights are clear. Another method is to tone to a bluish green in $\frac{1}{2}$ oz. 10 per cent. ammonium ferric citrate solution, $\frac{1}{2}$ oz. potassium ferricyanide 10 per cent. solution, water 5 oz., wash well, and then transfer to a 10 per cent. solution of chromic acid. Another method is with vanadium, thus:—Oxalic acid sat. sol., 120 m.; ferric chloride, 1 grain; ferric oxalate, 1 grain; potass ferricyanide, 2 grains; vanadium chloride, 2 grains; water, 6 oz. Mix in the above order. The vanadium should be first dissolved in a little hot hydrochloric acid 25 per cent. sol. Tone to a blueish green, and then wash till the print turns green.

STUDIO QUERY.—I am constructing or altering my studio, length about 31 ft., width 14 ft.; single slant, Robinson's design; glass running up from 4 ft. 6 in. wall, ridge to be central. What do you think of iron sashes, with rough rolled glass? I am told the glass is very green. Would ground glass be

best. Studio faces west. Light is practically unobstructed about 6 ft. at each end; to be solid. The height of ridge will be 12 or 14 feet. Shall I have too much glass? Would spring blinds be suitable, and what colours? I am very anxious about alteration, since I know something of the trouble of working the studio after nine years, with the sun upon the present nearly flat roof, and side light running at an angle background end being the narrowest. Your kind consideration and opinion of the above will be much appreciated.—MEMBER P.P.A.

Rolled glass will do very well, and it is to be had almost colourless. There will be plenty of glass, but we do not well see how you can make it less, as you will use both ends of the studio. However, as it is of a good width you might make 6 feet 6 inches of the ends solid instead of 6 feet. Spring blinds will be the most convenient for that form of studio and a dark blue, or a medium green, will be a suitable colour for that aspect.

J. W. COLLINS.—Klimsch and Co., Frankfort. The Metotype Company, 147, Seven Sisters Road, will, we think, also be able to supply you.

BROMIDE PRINTING MACHINE.—Is there any machine on the market to expedite the printing of bromide postcards? Who is the maker?—AUTO.

Messrs. Marion and Co., 22, Soho Square, and Kodak, Ltd., Clerkenwell Road; also The Tress Co., 205, Oxford Street, W., make such machines.

THE Coming Eclipse.—If the astronomers of Europe and America are nothing else, they are, at any rate, good sportsmen, as their plans for observing the coming total eclipse of the sun show. The eclipse takes place on August 30, and already nearly a dozen parties of observers are hurrying to various uncomfortable and out-of-the-way places between Labrador and Arabia in order to take photographs of the sun in semi-darkness. The elaborate preparations that are being made will be appreciated at their full value when it is stated that the eclipse will only be visible for three minutes at the outside. During those three minutes scores of photographs will be taken. Perhaps the most interesting party will be that of Sir Norman Lockyer, the distinguished head of the Solar Physics Laboratory, South Kensington. Sir Norman is already on his way to Algeria, accompanied by Lady Lockyer, his son, Dr. Lockyer, and Messrs. Maclean and Payne, well-known amateur astronomers. The two chief objects of the expeditions are to take photographs of the "corona"—the sun and its streamers—and of the spectra, or lines of light seen through the spectroscope. These photographs enable the astronomers to determine the composition of the sun.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Picture Postcards. In a recently issued report of the Postmaster-General, some interesting figures were given as to the enormous increase in the number of postcards which had been dealt with during the past twelve months, which amounted in all to 734½ millions. This is attributed by Lord Stanley to the increasing use of picture postcards, for of the above enormous number no less than 80 per cent. were private postcards. It is unnecessary for us to call the attention of the professional photographer to this, which must obviously be an extremely lucrative branch of business, for we know that many professionals make a special feature of it. The point to which we would direct attention, however, is the greater profit accruing on account of the time and labour saved by the adoption of some machine for turning out these cards at a rapid rate, and, as will be seen from the report of the Darmstadt Congress elsewhere, no less than six machines for rapidity printing bromide cards were there shown.

Bromide versus P.O.P. These machines, like others on the English market, are for the rapid production of bromide cards, and it may be advanced that the average individual has by now become tired of the unvarying black and white and matt and semi-matt surfaces, and prefers the warmer tones obtained with P.O.P. This, however, cannot be maintained as a serious objection, for with the various makes of glazed bromide cards now obtainable; and the numerous methods of toning bromides, P.O.P. may be fairly well simulated. Although we have mentioned the various methods of toning bromides, the only two processes which are at all likely to give satisfactory results are the old hypo-alum bath and the sulphide toning processes, and of these, undoubtedly, the former is to be preferred, if P.O.P. tones are considered desirable. Though all these bromide toning processes are more or

less satisfactory, we yet await one which will give us the true purple of P.O.P., and render the path of the picture postcard producer still easier than it is at the present moment.

* * *

The Darmstadt Congress.

On another page we publish a report sent by our representative at the Photographic Convention at Darmstadt. The conference began on August 15, and closes on Sunday next, and the entire meeting appears to have been characterised more with that pleasant spirit which the natives call "Gemüthlichkeit," than by the extent or importance of the proceedings. Business has been blended with pleasure in the way of luncheons, dinners, and excursions to neighbouring places of interest. The only communications of importance given during the congress have been by Dr. König, of the Höchst Dye Works, on "Pinatype," the new three-colour process, and by Professor Schmidt, of Karlsruhe, on a new direct-printing carbon paper of extreme simplicity, which appears to give results between carbon and gum-bichromate. This paper will, we understand, be put on the market early in October next. In the apparatus section of the exhibition the firms of Zeiss and Goerz show a good display of novelties, while the "Geka" Manufacturing Company and E. Merck also have their specialities on view. The portraits in the exhibition appear to be good examples of German work, although not very numerous. They are mostly brown or warm black in colour, with a somewhat yellowish tint, not altogether pleasant. Pigment papers and matt-celloidin toned in two baths to a yellow black seem to be the most popular printing processes, and the framing is striking; large black or dark rosewood frames being very numerous.

* * *

The R.P.S. and Salon.

Our readers, who are also potential exhibitors at the forthcoming exhibitions of the Royal Photographic Society, or of the "Linked Ring," are reminded that the latest dates for entries are rapidly approaching. Exhibitors in the Pictorial and Technical Sections of the "Royal," must have their exhibits delivered at the New Gallery, 121, Regent Street, London, W., on or before Thursday, September 7th. Exhibits may, however, be delivered by hand, unpacked, on Friday, September 8th, between 10 a.m. and 6 p.m., after which time and date no exhibit will be received. In the trade section stalls must be erected and exhibits arranged between the hours of 10 a.m. and 6 p.m., from September 11th to 16th, after which time any space allotted, but unoccupied, will be disposed of as the committee shall decide. Entries for the Photographic Salon close on Monday, September 4th, when exhibits must be delivered (on

that day only) accompanied by their entry form and without packing or wrappers of any kind, either personally or through an agent. Messrs. James Bourlet and Sons, 17, Nassau Street, London, W., have undertaken to deal with exhibits on the terms stated in the entry form. Entry forms for the R.P.S. Exhibition can be obtained from the Secretary, 66, Russell Square, W.C. For the Salon the hon. secretary is Mr. Reginald Craigie, whose address, in consequence of the demise of the Camera Club, we presume to be now the Blenheim Club, St. James' Square, London, W. We have a limited supply of entry forms for both exhibitions and will be pleased to send copies to any of our readers.

British Goods on the Continent.

Elsewhere this week we publish an interesting letter from a correspondent in Genoa, who alleges lack of enterprise on the part of British manufacturers in not catering more fully for the Continental market. We assume, from the experiences of "Itinerant Briton," that he is stating the case correctly, but cannot altogether agree with him when he says:—"Advertisements of British makes are *rare aves* in Continental photographic papers." The English manufacturers are extensive advertisers in the German papers devoted to photography, while in the French and Italian journals, to which our correspondent more particularly refers, we find the advertisements of Ilford Limited, Kodak, Marion, Edwards, Velox, Illingworth, Thornton-Pickard, Wellington, Barnet, Cadett, and the Cooke Lens, of constant recurrence. English camera makers are not, however, so much in evidence as the manufacturers of materials, and it is this fact that has probably given rise to our correspondent's observations.

The Dangers of Celluloid.

Considerable and frequent attention has of late been called to this subject, and an interesting fact has just come to light. A short time ago a fire occurred at a certain film-coating factory in Germany, from, it is stated, the spontaneous ignition of some celluloid stored in tins. Close by were a number of barrels filled with celluloid, and the heat was so great that the staves were charred; but there was no explosion and no great mass of fire—nothing but a narrow flame about three yards in height. The fire brigade prevented all but one door of the store-room from being opened, and the fire was soon got under. From this it seems obvious that celluloid in a compact mass only burns slowly and does not explode, though doubtless the limited supply of air in the case in question had something to do with the matter.

Washing Soda.

It is by no means uncommon to find washing soda recommended for development, and presumably on the supposition that it is carbonate of soda, and so it is plus α , the unknown quantity. We note in the annual report of the Medical Officer of Health for Paddington that twenty-seven samples of this useful household commodity were analysed during the year, with the result that nine samples were found to be adulterated with sodium sulphate to the extent of 70, 68, 51, 50, 43, and 42 per cent. in six of them. It is obvious that if one of these samples, or a similar one, had been used for developing, serious trouble might have been caused, not on account of any deleterious action of the sulphate, but because of the deficiency of alkali. The only action, apparently, of sulphate of soda is slightly restraining, and it was strongly recommended about twelve years ago as an excellent substitute for sodium sulphite. It is true that it has been stated that sodium sulphate causes a deeper yellow stain when pyro is used;

but this statement was made on the supposition that it would be present in the developer as the result of the oxidation of sulphite, it is only reasonable to assume that the deeper stain was not caused by the sulphate, but by the reduced quantity of sulphite.

The Solar Eclipse.

On Wednesday next, August 30, thousands of photographers in various parts of the world will be busy observing and photographing the much-discussed solar eclipse, which is regarded by astronomers as one of the most interesting for many years. The period of totality is of fairly long duration, and the line of central eclipse passes through several regions from Manitoba to Arabia, most of which are conveniently accessible for observation. The duration of the total phase is greatest in Spain, where it is about $3\frac{3}{4}$ minutes, while it is about $7\frac{1}{2}$ minutes in Labrador, and a little less than three minutes in Egypt. In England the eclipse is partial, about three-quarters only of the sun's disc being obscured; but even this, at the moment of greatest obscuration, i.e., about three and a half minutes past one o'clock, will be extremely interesting to observe and photograph. Well backed plates or films should be employed, and a lens of the greatest focal length, as a tele-objective should be used. The working aperture can be small, and an instantaneous exposure of about 1-20 to 1-100 of a second given. Weather permitting, a great deal of spectroscopic and other information about the sun's surroundings will, undoubtedly, be obtained. Perhaps the most interesting observations from an amateur's standpoint, according to "Scientific American," are those that will be made in the search for a possible small planet nearer the sun than Mercury, by photographing the whole region of the sky near the eclipsed sun. This has been done at several recent eclipses, without result, only known stars being found on the plates; but the brilliant success of photographic methods in finding new satellites makes one feel that the search for an intra-Mercurial planet ought to be continued a little longer.

The British Association.

The visit of the British Association to Cape Town, which terminated last Friday, although notable in many ways has not brought forth the extensive number of papers of far-reaching interest that one usually expects from the meetings of this body. Of papers of any importance to photographic workers there were none; while the domains of chemistry and optics have been but scantily noticed. The attendance at the meetings was not striking, but it was felt that this has been more than made up by the keenness of the members to see all that could be seen of the country, and to profit by a closer acquaintance with its problems. In fact, the geologists, zoologists, botanists, and other ardent investigators of the party revelled in the opportunities afforded them for the exploration of the country round Cape Town, and the meetings suffered from lack of attendance in consequence. The authors of papers, however, have been amply compensated for their small audiences by the generous publicity of the newspapers.

The Tourist Photographer.

We have more than once previously had occasion to draw attention to the lack of good taste displayed by many tourist photographers, who, while making the most of their trip to a strange country, snapshot anything and everything without consideration for the feelings of the natives. The bad odour into which the English tripper of a certain class has brought himself in many countries, due, no doubt, to the competition between excursion caterers, is to be deplored. When this kind of tripper is accompanied by a hand camera, his

terrors increase considerably, as nothing is sacred to him. An example of the extreme limits to which the assiduity of the tourist photographer can be carried comes from "The Hong-Kong Press," wherein an account of a Chinese execution is given. The comments conclude:—"It is really too bad that while some Europeans are writing against these public executions, others, innumerable tourists and globe-trotters, should be encouraging them; and, fancy, for instance, the indelicacy of a 'lady' taking snapshots of such things. I know of one instance of a tourist bribing the executioner to hold his sword in the air above the condemned man's head for three seconds, so that a clear picture might be secured."

PRINTING PROCESSES.

XI.—ALBUMEN PAPER.

In the last article (see page 623) the manipulations of the albumen paper process were brought up to the fixing and washing stages. Here, with some papers, a trouble may arise, namely, the blistering of the albumen, and it should here be mentioned that the more highly the paper is albumenised the more prone it is to blister. This trouble may make its appearance at different stages of the work. Sometimes the prints, directly they are put into the fixing solution, become covered with innumerable minute blisters. Occasionally they may not become larger as "blisters," but they often leave dark spots where they have been. At other times they will spread into larger ones in the washing of the prints. Frequently the blisters do not form until they have been for some time in the fixing bath, then they usually assume a larger size in the washing waters. The most general period when blisters become strongly in evidence is in the washing of the pictures after fixation. Here they sometimes attain a large size, especially if the washing be a prolonged one. We have seen them occasionally, as large as half a crown. Often, prints with blisters that have formed in the washing waters, when not very large, may be saved by puncturing the back of the paper with the point of a pin, and then carefully pressing them down between blotting paper.

The most general cause of blistering is the transferring of the prints suddenly from one solution to another of a different temperature and of a different density. Say, for example, they are taken from the toning bath or from the after-washing water, which has become slightly warmed by the hands, then put directly into a freshly made-up hypo bath, which is very much colder. In these circumstances blisters may generally be expected, as they usually take the form first referred to. Another prolific source of the trouble is immersing the prints direct from the fixing bath, which is a tolerably dense solution, into the washing water, which may also be of a different temperature.

Having indicated the chief causes of the trouble, the way to avoid them is easily indicated. The temperature of the fixing bath should always be brought up to that of the toning solution before the prints are put into it. This is the best means of preventing the first stage of blistering. With a paper that has a tendency to blister, instead of taking the prints out of the fixing bath and plunging them direct into plain water, they should be taken out, and the solution diluted with an equal bulk of water, and then replaced in that for a few minutes, being kept in motion the while. In obstinate cases the hypo may be further diluted before the prints are put into the washing water. An alternative plan is to transfer the prints from the fixing bath to a strong solution of common salt in water, and gradually diluting that, as in the case of the hypo bath, before putting them in plain water. Even with the most

troublesome papers if these precautions are taken blisters may be avoided. With some paper it should be said there is no tendency whatever to blistering. Here is another way of preventing blistering that, in our hands, has never failed, even with the most obdurate paper we have ever had to deal with. It is to immerse the prints, before beginning to wash out the free nitrate of silver, in methylated spirit for a few minutes, and then proceeding in the usual way with the other manipulations. There are, however, two objections that may be raised to this method. The first is that the spirit renders the paper semi-transparent, so that the effect of the toning solution is not so easily judged. The second is the expense of the spirit; still it is a sure preventive.

Here is a trouble that may arise with some highly glossy albumen papers. When the prints are mounted they are seen to be reticulated, or rather covered with minute cracks. It is usual in drying albumen prints to lay them out exposed to the air; as they dry they curl up, and as they are straightened out for trimming and mounting the albumen cracks into minute fissures, hence the appearance. The remedy for this is to dry the prints between blotting boards so that they are kept flat all the while, or to mount them while they are still wet from the washing waters.

In this and the foregoing articles on the albumen paper process, we have assumed that the paper employed has been sensitised by the user, for many who work this process aver that the home sensitised paper yields better results than can be obtained on the ready sensitised ones, and there seem to be some grounds for this idea so far as deep tones are concerned. But the improvements made during the past few years by the manufacturers of ready sensitised papers leave little to be desired in this direction. This has led many who used to sensitise their own papers to now purchase the ready sensitised ones, in order to save trouble for one reason, and for another that it entails less waste through the paper going bad before it can be all used up.

With regard to the manipulation of the two kinds of paper there is very little difference, and what has already been said with reference to toning, fixing, general manipulation, etc., of the home-sensitised papers, applies equally well to those which are bought ready sensitised. There is, however, this difference between the two: The ready sensitised does not contain so much free nitrate of silver as do those of home sensitising; its place is largely taken by organic salts of silver—the citrate, or tartrate. The paper also contains a good amount of free acid, which, if not removed, somewhat retards the toning, especially as regards deep colours. This acid, if left in the paper, contaminates the toning solution and conduces to a reduction of the gold if the bath be kept for future use. It is therefore a good plan with this paper, after the free silver has been washed out, to immerse the print for a few minutes in a very dilute solution of carbonate of soda—say a crystal of common washing soda, the size of a walnut, to a quart or so of water, and then rinse in plain water. This, by neutralising any acid that might remain, greatly facilitates the toning, particularly if dark tones are desired. It also tends to preserve the toning solution from a spontaneous deposition of the gold if the bath be kept for further use. There is one point of difference between the two kinds of paper which may be referred to. In the last article on this subject reference was made to the hygroscopic conditions under which the printing should be conducted—that is with the home sensitised the paper should not be abnormally dry. This does not apply to the commercial ready sensitised papers, as the presence of the organic salts in the paper seems to make one more independent of conditions such as those referred to in the former article.

SUCCESS IN THE STUDIO.

THERE is no fixed rule for success. As in my recent article on "Novelties," all I can do is to give a few suggestions, which may be useful, one here, another there, to some photographer who is dissatisfied with his results. If my ideas set such a man thinking a little, they should lead to some definite result, and so achieve my purpose. For advice is usually suggestive rather than definitive, and can seldom be followed exactly.

Handling the Sitter.

How often, I wonder, do photographers consider their business from the viewpoint of their sitters? "Oh, he is a horrid man," exclaimed a fair photographed one to me recently. The trouble was that he had kept her under the skylight for forty minutes, posing and re-posing, now altering the hands, now adjusting some line or fold of the skirt. She was a somewhat nervous sitter, and at the end of the experience felt considerably tired. The photographer I know well; he is a man of artistic ideas and knowledge, but he is also a little nervous and fussy, and nervous people before and behind the camera are not good. The result is a loss to photographers at large, for the young lady will now have a feeling against being photographed. She will not understand that it was merely the failure of one particular photographer; she will fight shy of all studios.

I daresay that if a lady called by appointment and spent only three minutes under the skylight she would have a secret feeling that she was not getting value for her money, even if the pictures were an unqualified success. Tact is required in this as in all things, but a photographer should know his art and be able to achieve his results without tiring his customer.

Too Much Pose.

The same pose will not suit all people; but sitters may be classified into groups and the same set of rules applicable to all in one group—of course, with modifications. The lady who appeared before the horrid man has a thin face and figure. A full face, the lady sitting, would with a little judicious retouching have made a satisfactory picture. And she had no stated preference—she merely wanted a picture. But she was tried in half-a-dozen different postures, and under almost every possible lighting. And equally bad, she was worried about the pose of her hands and her manner of standing until she felt that her deportment was full of faults. To draw attention to a nervous fault inevitably intensifies it. Had the photographer conversed of anything rather than the pose he would have achieved better results. If he could not diplomatically have attained what he wanted without distracting

his customer so much, it would have been better to let the natural fault pass.

Flattery.

He made the mistake of making the poor girl "feel small." Now flattery is a rather difficult subject and should be handled carefully—it must not be laid on with a trowel. I do not know how American photographers rank in this art, but if they are anything like the general run of their compatriots they must be ahead of us. I have met a number of Americans on this side, and the way they make you feel a fine fellow is almost past belief. It is not till after they have gone that you suddenly awake, and smile to yourself. It comes natural to them. If the photographer has a good digestion, and likes his profession, he can have a cordial welcome for everyone who calls—and a genuine one, even apart from the money in it. Let the people "feel good," as those same Americans say, and it will be reflected in the portrait secured. Do not call attention to faults; rather emphasise the pleasure felt in the general appearance. And remember that men can absorb just as much flattery as women can. Sometimes a request for permission to exhibit one of the pictures in the window gives pleasure. It suggests that to do so is a privilege appreciated by the photographer, and the natural inference pleases the sitter.

Success.

Everyone follows the winning side. Indications of success lead towards it. The studio that looks business-like and clean, the photographer who is alert and expeditious, convey a feeling of business being done. And the sitter goes where she thinks others go, for the verdict of the majority generally rules. Non-success is a serious matter, but a confession of non-success is fatal. At whatever cost (and the cost is usually the direction of personal effort rather than cash), business appearance must be kept up.

The Dressing-room.

Articles are often written on the management and importance of the reception-room and of the studios, but we seldom hear of the indispensable room which comes between them. The dressing-room is often a very tiny place, but that is no deterrent. But I have seen dressing rooms calculated to scare away the most desirable class of sitters. I was in one recently where there was a tiny washstand and table with mirror. But by the wash-bowl was a dirty towel! Fancy a lady liking to use such a thing. If washing were necessary, at least a fair clean towel should be provided. It is not a pleasant subject to probe, and so we will let it go, merely saying that necessary as cleanliness is, it is doubly necessary in this little room.

ALEXANDER BRADFORD.

ALLEGED ESPIONAGE.—A telegram has appeared in the Berlin and Bremen Press in which it is stated that an English pleasure yacht which arrived at Wilhelmshaven on Saturday and left Monday was immediately followed by a German destroyer under the command of a captain. The destroyer had been sent in the track of the yacht because two members of the English crew, it was stated, had been seen taking photographs of the harbour defences. Both Englishmen, according to this report, had been arrested on a charge of espionage. The Hamburg correspondent of the "Daily Mail" writes, however, on Tuesday last, and says:—"I am informed that the report has been greatly exaggerated. The two Englishmen were allowed, after an explanation, to continue their voyage. Nothing is known of the incident at the Wilhelmshaven coastguard station."

New Rotary Show Cards.—The Rotary Photographic Company, Limited, of 12, New Union Street, Moorfields, E.C., have added to their already large series of attractive show cards a new set depicting

the "Muses." Discreetly draped models from the studios of Reutlinger, of Paris, adequately represent Clio, Thalia, Urania, Euterpe, Calliope, Melpomene, Erato, Terpsichore, and Polyhymnia, in pleasing poses. We can recommend this collection of fine bromide prints to photographic dealers, to whom a set will be forwarded on receipt of trade card. They will make a very striking display for the winter season.

A GIANT CAMERA.—The Hamburg expedition to observe the eclipse of the sun on August 30, says the "Express," has a giant camera, 70 feet long, by which, it is hoped, six photos may be taken on plates 34 in. by 34 in.

From Mr. Henry Ward, of 9, Belgrave Road, Leicester, we have received a price list of enlargements which he undertakes to make from customers' negatives. Various styles are listed, and the prices are moderate. A copy of the list will be sent free on application.

VIGNETTES AND VIGNETTING.

I.

THE poet sees in the face the index of the soul, and notes its expression in the eyes and mouth. Not that the neck, shoulders, and bust are disregarded; they are usually regarded more as the supports of the head. When our eyes scan the features of another the accessories become blurred, indistinct, and fade away.

In Defence of the Vignette.

Is not this a natural vignette? Is not the vignette the most natural expression of portraiture, the view that the eye itself sends to the brain? Yet what scant courtesy the art of vignetting receives at the hands of photographic writers. Emerson, at least, should know better; yet, because principally, if not solely, he once saw a mechanical printer "who did an extensive business in vignetted heads, and it was a source of great amusement to us to watch the mechanical application of the vignettes by the 'head' printer," decries the style altogether. He had some excuse, for he continues, "This is, of course, another source of the mechanical appearance of ordinary photographs; for by vignetting fifty different heads a certain uniformity must result, the loss of all individuality, character, and, of course, art."

How not to Vignette.

Nor do Robinson and Abney in their work on silver printing give much attention to the vignette. One method is described—a method I have never seen used in any printing room, nor am I likely to, for with all due respect to my worthy and approved good master of the days of my photographic beginnings, the method given in that useful little book is, of all methods of vignetting, the most mechanical, and of all mechanical methods the clumsiest and the worst. Nor do the dealers in photographic stores help one out. If vignetting is mechanical, and if it is accompanied by dull uniformity, what good can be got out of metal vignettes and glass vignettes? Surely the mechanical is made more mechanical still. One good thing—good, that is, if used in skilful hands—do they supply, and that is the vignette clipper. It is something towards a recognition of the fact that each portrait to be artistically vignetted must be specially vignetted. Each portrait must be treated on its own merits.

A Practical Method.

More than that, the cutting-out-and-clipping-round method is an especially good one for a cloudy day and in a cloudy country, more especially with silver printing. But when one regards the work of a busy studio in a sunny clime, where tissue paper in single or double folds must take the place of the white cloud in subduing the direct rays of the sun, the method about to be described here is undoubtedly best. But even in the bright but cloudy summer weather of England, it has much to recommend it. The frames may be turned towards the sun if there is sun, or should the sky become overcast, and platinum prints be jeopardised by not being finished ere the day closes, the tissue paper may be wholly or partially torn away. But enough of the introduction; let us come to the practical method and the tools required.

Printing Frames.

These need be only of the commonest type in teak or deal; for all sizes up to whole plate, in fact, the commonest type is the best. The depth of the quarter and cabinet (half plate, of course) generally averages a quarter of an inch; by depth, I mean the thickness of the ledge on which the glass rests; the thickness of the back is immaterial. The negative should never rest in the frame itself, but should lie on a sheet of glass, for you will then usually find that if you have the misfortune to drop the frame, it is the clean glass and not the negative that is cracked. This clean glass is, of course, a spoilt plate with the

film removed. A flat piece should be selected, thin as possible, where quarters and midgets are concerned; flat but thicker for cabinets. With whole plate frames the depth, including plain glass, should not be less than half an inch, and may be increased if desired by the thickness of cardboard forming the vignette.

The Vignette.

Cardboard, tissue paper, and paint, to be fixed in position by four or more ordinary tintacks. Spoilt mounts do very well for the purpose; they should be thin for midgets and quarters, thick for whole plates. The tissue paper to cover the opening in the cardboard is of the ordinary kind. This is affixed to the opening by pasting round the latter with ordinary paste or the starch mountant just discarded by the mounter as being a day stale. Paste round the opening in the cardboard and stretch the tissue paper over it. For the paint, I have seen ordinary

Brunswick black used, but it is rather messy; I prefer lamp black or Venetian red myself, and of the two I like the Venetian red best. Burnt Sienna may do as well, but I have not tried it. Whichever is used, the mixture of pigment and weak gum is a most handy thing to have by one. The pigment should not be stinted, as it is better to make an opaque mark on the tissue with one stroke that quickly dries, and the gum and pigment serves another useful purpose. Although it is not so good as Brunswick black or Nixey's black enamel for anti-halation purposes, it is all that is necessary in most cases.

Tools at Hand.

You have now your frame, protecting glass, and negative; your cardboard, tintacks, tissue paper, waste, and paint, with, of course, a paint brush. The brush may be either a very small bristle brush or a medium-sized camel's hair brush that has been a bit worn down. A small hammer and a pencil and a sharp, strong penknife completes your outfit. The printing-room

scissors, if sufficiently large, are a handy tool, for you can not only cut your paper with them, and even the cardboard to make your vignettes, but by gripping the blades they make a handy tack hammer if your aim is sufficiently true. You do not require to keep them sharp; a knife is good enough to cut your paper with, and for cutting cardboard for your purposes blunt scissors are as good as sharp ones. If sharpened they only get blunt again.

How to Make the Vignette.

Now, having got your tools together, not a very expensive assortment, the mechanical work you have to do can be thus detailed:—

1. Cut an opening of the required shape that shall take in all you want to be deeply printed and no more, leaving the spreading of the light to do the main work of gradating beyond.

2. Paste your tissue over the opening, and paint it to gradate the spreading of the light beyond. To do this you must hold the frame containing the protecting glass and negative face upwards, of course, at an angle of about thirty degrees with the horizontal, and apply the strokes of the brush from underneath. As you cannot actually see the brush through the paper, but only see the strokes you make, this is to some extent a matter of feeling; it is surprising, however, to find how soon you get used to a seemingly difficult task. The first trick of the tyro is to turn the frame over to look at his brush-strokes, and so endanger the safety of the negative, but he soon gets out of this clumsy proceeding. What the vignette looks like is shown in the accompanying illustration, where the portrait is that of a gentleman, full face, with a dark coat.

An Alternative Method.

Perhaps I should mention one other good method which "makes the punishment fit the crime," or, in other words, necessitates each negative being treated on its own merits. It consists in using an open cut-out and modifying the diffusion of light by judiciously tucking in cotton-wool. A cardboard cut-out is tacked on the back of the frame, the opening in the card being a little larger than would be used when vignette clippers are requisitioned. It is a good method, but too laborious for usage in a busy studio. The method of tissue paper and paint

has all the advantages and none of the disadvantages of other methods. You take advantage of direct sunlight when the weather affords it, for if the light is too strong, what is easier than to clap on extra tissue? Should the sky be overcast, the one thickness of tissue is no great disadvantage, for the bright clouds of England are as brilliant a reflector as they are a good diffuser. When the worst comes to the worst, when the sky darkens, when your platinotype paper is in danger of being spoilt if not finished before the close of day, what is easier than to rip out with the finger as much of the tissue as you think fit, so as to be able to pass your paper through the oxalate bath before closing the studio and going home? When morning comes you can replace the tissue and paper in a few minutes.

Rapidity.

One word more on this "mechanical part" so-called. A smart workman can and does actually cut tissue, and paint a cabinet or even whole-plate vignetting mask in ten minutes, but when cut-outs are plentiful and sorted into styles the time occupied for each cabinet should not be longer than five minutes. I have seen it done, not once as a *tour de force*, but continuously for three hours. Where? you ask. At the most fashionable studio in Cape Town a few years back, when fashionable lady, gallant officer, and enthusiastic Town Guard (Yes! capital letters, please) were flocking for their counterfeit presentations.

There is just another word to be said about the use of cotton-wool. It may in some cases be advantageously inserted between tissue mask and negative. The tyro may find it useful to further safeguard the spreading of the light when the sitter has worn a dark dress or black coat. The expert very seldom needs it; in his hands he appreciates at once the amount of masking and painting to be done. Any little improving he may leave to the actual printer who is watching the frames. A variation in the angle at which the frame is presented to the light will easily correct minor miscalculations.

But at this point a fresh chapter must be begun, and some directions given for special cases of the various types to be dealt with.

C. RAY WOODS.

THE WEEK IN HISTORY.

Camera Pictures in 1829.

As showing the progress which Niepce made by slow degrees, I quote here from a letter of his to Lemaitre, written ten years before the publication of the processes of Talbot and Daguerre. His brother Claude had died some months before, and the account of his work appears to have afterwards reached the sympathetic ear of Lemaitre. "I see with satisfaction," he writes, "that I am now reaching the end at which I have aimed. I have discontinued copying engraving, and am working direct from nature with one of Wollaston's perfected cameras. The periscopic lenses give me much better results than those I have obtained with ordinary objectives, or even with the meniscus lens of Chevalier."

An Early View of the Niepce-Daguerre Controversy.

The precise shares in the perfection of the process which finally became known as Daguerreotype was the subject of much dispute in the early days of photography, but my readers, at any rate, should be clear in their minds as to the credit which Niepce Niepce deserves. Certain it is that he worked out a complete though crude method of photo-engraving, and it is highly probable that Daguerre was largely indebted for his knowledge to the store of information which his partner had accumulated during his fifteen years' work. As showing how largely conjecture entered into the early criticisms of these early

photographic inventors, I cannot do better than quote a passage from the "Athenæum" of March 9, 1839:—

The specimens in the possession of M. Bauer and others, given at the time to Mr. Cussels, of Richmond, have been obligingly submitted to our examination. They may be divided into pictures copied from engravings and pictures copied from nature. The best specimen of a copy from an engraving belongs to Mrs. Cussels, and though somewhat different in its style and general effects, it is not, considering that it has been exposed for more than ten years to all the casualties of dust and damp, much inferior to similar copies shown to us, when lately in Paris, by M. Daguerre. M. Bauer possesses the only copy of a picture taken from nature, but this, so far from being equal to the specimens produced by M. Daguerre in 1839, is even more shadowy and indistinct than any of the earlier specimens of the art which we saw in Paris, and immeasurably inferior to the later works. That the early process of M. Niepce and the present one of M. Daguerre are essentially the same, though greatly improved, we cannot doubt. As M. Daguerre has good and sufficient reason for not making his secret known for the present, the pictures exhibited by him are covered to the very edge with paper; notwithstanding which we came to the conclusion that the material was either pewter highly polished or washed with silver, and all the specimens in the possession of

M. Bauer and Mr. Cussels are on pewter, apparently coated with a very thin coating of transparent varnish, but whether this varnish was applied before receiving the impressions or subsequently to fix them is not obvious. We incline to the latter opinion. The most curious fact in relation to the discovery yet remains to be told. It would appear, considering the character of the pictures all but impossible that impressions from them could be multiplied after the manner of an engraving. M. Daguerre, indeed, stated to us that it was impossible, and it is but reasonable to believe that he is as fully informed of the nature and extent of the

discoveries as M. Niepce himself. Yet in 1827 M. Niepce not only declared that it was possible, but produced specimens of such multiplied copies, and M. Bauer has now in his possession not only copies of engravings fixed permanently by the action of light, not only scenes from nature, but metallic plates engraved and engravings copied from them; and he understood and believes that no engraving tool was used, but that the drawings were fixed by the action of light, and the plates subsequently engraved by a chemical process discovered by M. Niepce.—The "Athenæum," 1839, March 9, p. 187.

HISTORICUS.

CONTROLLING EXPOSURE AND DEVELOPMENT IN MAKING BROMIDE ENLARGEMENTS.

III.

Practical Development.

For practical development we employ two developers—(a) well-restrained adurol (formula given above); (b) dilute rodinal unrestrained strength 10 minims to 4 oz. water.

Technique.

First soak the enlargement in clean water until it is quite limp, drain, then pour on the restrained adurol developer, and develop until our blacks are nearly the intensity we require them to be. Now rinse quickly for one minute. If the whites and white-greys are not sufficiently developed, as is most likely (for they are being held back by the potass. bromide), we pour on the dilute rodinal and develop until they are just what we wish. The rodinal will not appreciably deepen the black, being so dilute, but it will act on the portions that hitherto have been restrained (as rodinal is unsusceptible to bromide), and they will tend to jump to their normal degree of development; hence the use of dilute rodinal. This method allows us to control our gradations perfectly; it also allows for a considerable amount of over-exposure—in fact, it is better to be sure that the enlargement has received slight over-exposure, for if under-exposed the white will "hang-fire," and nothing will make a satisfactory picture.

Two very important points must be considered:—

1. We must have plenty of yellow light with which to examine the progress of development, otherwise we may find that, what looked perfect by weak yellow light is distressingly weak after fixing when viewed by white light. I find that if plenty of yellow light is used, when the appearance in the developer is the same as when viewed after fixing by white light. You will notice that directly you put the enlargement into the hypo it becomes much darker when viewed by yellow light; also, if you simply washed after development and then examined the picture by white light, it will appear very weak, although it was satisfactory by yellow light. Hence we see that the fixing bath actually darkens the picture, although we do not take it into consideration in judging the degree of development.

2. We must have our developer somewhere near the right temperature (65 deg. F.). I have found it impossible to get a good result when the developer was too cold, and, on the other hand, if the developer is too hot, fog may appear. We may represent what usually occurs when working with these two developers thus:—

(It is assumed in the diagram that there is slight over-exposure.)

ACD represents the work of the restrained adurol developer.

ABC represents the work of the rodinal developer.

AB represents the correct line of gradation.

XY represents the limit of development.

Consider three cases.

-1. Suppose we have given four times the correct exposure, but are not aware of the fact, we develop first in the adurol for some time until our blacks are nearly developed enough, then rinse, transfer to rodinal—a short application of which is needed to make the result satisfactory.

2. Twice correct exposure (though unaware of fact). Develop as usual for the blacks. Rinse. A longer application of rodinal is needed.

3. Correct exposure (though unaware of fact). Develop as usual in adurol for blacks. Rinse. Result, soot and whitewash effect; a much longer time in the rodinal is needed to soften or fill in the high lights.

So we see the method of procedure is exactly the same in each case.

I have here five prints, four of which are identical; the fifth differs somewhat:—

No. 1 was given the correct exposure and developed to the limit with rodinal (30 minims to 1 oz.), giving good gradation.

Fig. 6.

No. 2 was given the correct exposure, and developed as indicated in Case 3 above. Same result.

No. 3 was given twice the correct exposure and developed as above. Result, exactly the same colour and gradation as in No. 1.

No. 4 was given four times the correct exposure and developed as above. Result, exactly the same gradation as in No. 1, but more of an engraving black, not so blue as No. 1.

No. 5 was given four times the correct exposure and developed in the restrained adurol alone, until the high lights were developed to the same degree as in No. 1. Result, the blacks are blocked up. This shows that the limit of useful over-exposure had not been reached.

So we see that we have great latitude in exposure. Of course, I do not recommend this great over-exposure, but we see how safe we are when we use this method of development.

The same method, too, is applicable to a negative of normal or flat contrast; but if the negative is very hard, the method of procedure is somewhat modified.

Dealing with Hard Negatives.

The most satisfactory method of dealing with hard negatives is to reduce them with persulphate of ammonium. You should never produce such a negative, and if you employ the Watkins factorial system of development, you will never do so. If, however, you object to reducing the negative, there is a method which is quite satisfactory, which I will now describe.

We make quite sure that we have given sufficient exposure that the densest portions of the negative that we want to print have printed through.

Then for a medium reduction of contrast we immerse the undeveloped paper in a solution of potassium bichromate, strength 1 in 2,000 of water (5 gr. in 21 oz.). Now we wash quickly for one minute and then develop as usual, first in the restrained developer and then in rodinal; we will then get a perfect result.

This method of reducing contrasts was introduced by Mr. Sterry, of London. It works satisfactorily with Kodak, Barnet, Wellington, Empire, and Pearl papers. These are the only papers I have tried it with; probably it will work with all bromide papers. The time of immersion may vary with the paper employed.

Roughly, for medium reduction of contrast the times of immersion are:—Kodak, Empire, Barnet, 20 secs.; Pearl, 10 secs.; Wellington, 40 secs. These figures may not be quite accurate, but anyone can make tests. The longer the paper is kept in the bichromate solution the greater the reduction of contrast.

Explanation.

We will refer back to Fig. 2 (see B. J. last week). Suppose our negative or print meter to be too hard, and suppose we have given sufficient exposure, that our tones bordering on the whites are exposed enough; now our blacks will be blocked up.

AC represents the silver bromide, capable of being reduced if we carry development to the limit, and EB is the height of a black step. Then we see that the shadows from D to E will all be black and blocked up. If, now, we put the undeveloped print in the bichromate solution, the effect is to slice off a portion, ACE, and leave us with a limit line, say AE—that is, if we now develop to the limit we could only reach AE. So we see that the effect of the bichromate is tantamount to reducing the contrast of the negative. The longer we leave the print in the bichromate solution the flatter the line AE becomes. I find that the resulting colour is not at all influenced by the bichromate when using this weak bath. Now, the use of potass. bichromate does not interfere with the working of the developers, and so, if we have unknowingly over-exposed, we can still use the two developers and get a perfect result.

Hence we have full control over our gradations, and are not dependent on a correct exposure.

If we knew the exact exposure we could use rodinal, and not develop to the limit as before explained, and thus get a softer result.

But then we are dependent on a correct exposure.

Suppose we had unwittingly over-exposed, our whites would suffer if we started with rodinal. Hence the bichromate method is preferable.

We need not employ the bichromate method unless the negative is very hard, as daylight enlarging tends to soften the gradation. Thus a negative, which gave perfect gradation by contact when developed to the limit, would give a flatter result when daylight enlarging is used, and developed to the limit, even if the correct exposure was given. A negative too hard for glossy paper will give a perfect daylight enlargement without the use of the bichromate.

Sundr Notes.

1. I have illustrated the method of development with contact prints for convenience. I need hardly add that the argument applies exactly to enlargements.

2. The term "density" has been used in the commonly-accepted meaning as being synonymous with opacity, and not in the scientific meaning adopted by Messrs. Hunter and Driffeld.

3. I would advise those who intend to try this method of development to experiment on contact prints, until they find out the amount of yellow light to use, and the times for transferring the print from solution to solution. In practice it is delightfully simple.

4. Once the principles of development are grasped we can apply this method of development to other developers—e.g., we may use (first) hydroquinone, and then metol, or even apply it to a single developer of the intermediate class, such as amidol. In this case we would use the amidol developer, and strong and heavily restrained, and then for the second developer dilute unrestrained amidol, made very slightly, alkaline with sod. carb., good formulae being:—

Amidol	8 gr.	} For the first developer.
Potass. bromide	12 "	
Sulphite soda (cryst)	80 "	
Water	2 oz.	
Amidol	4 gr.	} For the second developer.
Sulphite soda (cryst)	40 "	
Sodium carbonate	2 "	
Water	2 oz.	

The latitude is as great as with the adurol and rodinal.

5. It is feasible when we want to block out irritating high lights, such as sky through trees, to apply locally some strong developer with a paint brush after development is complete; then, evidently, we must over-expose, or expose locally by means of keeping a card with a hole in it moving over the spot.

6. It is also feasible, after fixing and washing, before drying, to locally reduce where needed, with a stainless reducer, such as

Saturated sol. of iodine in alcohol	30 minims.
Saturated sol. of potass cyanide	40 minims.
Water	1 oz.

If it acts too quickly, dilute with water.

7. I prefer an acid fixing bath when properly compounded, such as

Hypo	16 oz.
Pot. metabisulphite	6½ dr.
Water	64 oz.

First mix the metabisulphite and then the hypo. This bath is quite stable.

If the paper is liable to blister add 75 gr. of chrome alum to the metabisulphite solution before adding the hypo.; the bath will then be perfectly stable. Some papers are already hardened; they will crack when straightening if alum is used.

8. If you add ammonium chloride to the first washing bath to the extent of 10 per cent., the hypo. will wash out in half the time, as ammonium thiosulphate is formed, and this is more soluble and more quickly diffusible than the sodium salt.

9. If you find the colour of the enlargement too warm, from over-exposure, you can change it to a cold or even blue-black by immersion in

Gold chloride	1 gr.
Ammon. sulphocyanide	20 gr.
Water	1 oz.

The toning is fairly rapid, much, however, of the blue disappears on drying; if the print is left in this for some time you get slight intensification also.

10. If you wish to tone by the sulphureting process it is well to use a rapid paper and over-expose as little as possible, also to use amidol.

If you wish to tone by the hypo-alum method you must over-expose and over-develop somewhat, because of the reduction in toning.

N. C. BECK.

PROCESS WORK IN AMERICA.

II.

Three-colour Abandoned.

MANY photo-engraving firms have abandoned the purely three-colour method, regarding it as an impossibility to attain good results, and were working four-colour processes in which the colour results were produced by the skill of the etchers, the photographic negatives playing a comparatively unimportant part. Where three-colour is being worked on anything like a commercial scale, dry plates are being used, these being of the panchromatic type. This naturally necessitates dense filters, and the exposures are very long. In the case of the red filter, they often leave the camera standing with lens uncapped overnight, so that the exposure may go on in the early morning light. In spite of these roundabout methods I must confess that the results I saw produced by such firms as the American Three Colour Company, the Electro-Light Engraving Company, the Zeese Wilkinson Company, the Colorplate Company, and others, were very fine. The extent and variety of the work being done by the American Three Colour Company, in New York and Chicago especially were simply marvellous. This concern is an immense organisation, devoted entirely to the production and printing of colour blocks. The greater part is three colour, but some excellent four-colour work was shown me.

Newspaper Illustrations.

The extent to which newspapers are illustrated in America is remarkable, especially when it is remembered that it is a practice of comparatively recent growth. It is quite exceptional to find any important newspaper without its art department and photo-engraving department. So surfeited have the public become with illustrations that it has given rise to a revulsion of feeling against the innovation, and I heard one business man in New York remark that he always bought the "Sun," because it did not contain any illustrations.

Coarse half-tones produced with a screen of 65 lines to the inch are used freely in the daily papers, and the wonder is that they come out so well, considering the rush with which the illustrations have to be got out. Most of these half-tones are relieved with an ornamental line border which is etched at the same time by cutting out the stripped films and fitting them together. It is really surprising to see the ease and facility with which the stripping operation is conducted, and one cannot afterwards wonder why they do not use prisms. A number of small films are laid down on one glass to form a large plate, and the etcher is given from about 45 to 75 minutes to carry the plate through. He adopts the dragon's blood powdering method, using the brush exclusively for forming the acid resist. The European method of rolling up with ink is scoffed at.

Etching by Machine.

In the office of the "Philadelphia Press," I saw an ingenious automatic machine, invented by Mr. Louis E. Levy, for performing this powdering operation, and it was remarkable to see the precision with which the plate passed under the powdering brushes, thence over a series of gas jets, which lit up as the plate reached them, and was finally cooled by an air blast. It took about five minutes to powder the plate four ways in this machine, and the quickest etcher would not claim to do it in less than eight minutes, whilst this would be a speed he could not maintain.

In the same room I saw Levy's acid blast-etching machine at work, and this was an equally marvellous piece of mechanism. The plate is fixed to the lid of the trough, the blast of a blower turned on with about 2 or 3 lbs. pressure, and this drove the acid through a large number of sprays in the bottom of the trough, so that it impinged on

the plate with great force. In 30 seconds the plate had been etched to a quite perceptible depth. A second etching of 60 seconds, and a third etching of 90 seconds, finished the plate to the required depth, in most cases. No fumes escape from the machine, and the acid is not so strong as would be used for the old hand tub etching. The work is also much cleaner and sharper. Both line and half-tone work is etched in the machine, the former requiring the longest time, but in any case being far quicker than the hand method. These machines seem likely to revolutionise the production of newspaper illustrations, if the men give them a fair chance.

Besides the artists and photo-engravers, the newspapers maintain a force of outdoor photographers, who are expected to bring in some sort of negatives with even the most unpromising opportunities, and these men have acquired wonderful smartness, not to say audacity, in getting results.

Newspaper Illustrations in Colour.

The Sunday editions of most of the important newspapers are printed in colours, and considering the speed at which the printing has to be done, are marvellous productions. The purely photographic three-colour process cannot so far be applied for this purpose, being too delicate. The colours are accordingly laid down by hand from a black key plate, with the aid of "shading mediums" (gelatine films having lines or stipple in relief on them and which can be inked and transferred). The printing machine is a wonderful mass of mechanism, the white paper being fed in from a reel at one end and coming out at the other printed in 4 to 6 colours, cut and folded as a finished newspaper at the rate of not less than 10,000 per hour. The colours are rather thin and tinty, but improvement is gradually being made in the printing, and in time it will no doubt be possible to produce the regular three-colour print, so that we shall eventually have daily newspapers illustrating current events in colour. If money can command such a thing it will be lavishly forthcoming, for no expenditure seems too much for the enterprising proprietors of these great American newspapers. Several of them have recently installed the Auto-plate, a machine which produces stereo printing plates with about the same speed and facility as a sausage-machine turns out its savoury product. I think you only realise what American hustle means when you go through these big American newspaper offices about publication time, and if you have any nerves you are glad to get quickly away.

Stereotyping and Electrotyping Illustrations.

Stereotyping is almost a lost art in the States, or possibly it has never been found. It only survives in the newspaper offices, and it is, generally speaking, poorly done, when it comes to handling cuts. Much better methods are being worked in England, where the plastic-moulded stereo and nickel-facing are ousting electrotypes for illustrated periodical work. In the States they have to use electrotypes for the colour presses printing the Sunday editions, and all book and periodical work is done by electrotyping.

Lithography, Collotype, and Photogravure.

Lithography is largely practised, and is almost monopolised by big concerns. One of the largest and most important houses I visited was the American Lithographic Company, who occupy a large block in the heart of New York. The whole of the roof is devoted to the photographic and process studios, and photography is applied in many ways to lithographic work. Collodion emulsion is here worked successfully by Mr. A. C. Austin, a well-known worker and technical writer on process work. They also have a process of making enlarged half-tone negatives for posters, the small positive being very evenly illuminated by means of a battery of six mercury vapour

tubes, no condensers, therefore, being required. This firm are attempting rotary intaglio photogravure, and have got so far as to show very promising results. But the most wonderful sight in this establishment is the rotary lithographic machine which prints six colours lithographically, and a black letterpress from stereo plates. The lithographic work is transferred to cylinders which are coated electrolytically with zinc. Very large sheets of colour work are printed from the web at a high rate of speed and of good quality. The machines have been designed and built on the premises, and are covered by about forty patents.

In regard to colotype, I only came across one firm working it, and that was in the heart of the grimy and windy city of Chicago, and I heard they were doing well. I know there are, perhaps, two or three other firms working this process, but no one takes colotype seriously. It is not commercial enough for the American, for there are times when the process baffles his efforts to hustle it along. Photogravure is also very little worked, because it requires too much of the "personal equation," and the American business man can see no money in it, though it is a curious fact that Uncle Sam's paper money is printed in the quaint old-world way in which photogravures are printed. If you go into the Bureau of Engraving and Printing in Washington you see a room in which there are hundreds of little copper-plate presses, each operated by a young man and a girl. The former inks and wipes the plate and pulls it through, whilst the girl lays on and takes off the paper.

Conclusion.

"What do you think of America?" is the question I have been asked over and over again with special reference to process work. I can only say that what impressed me most was the size of the firms and the excellence of their business organisation. Process was seen at its best when combined with artistic printing, and the most successful firms appeared to be those who best brought together these two kindred arts in the production of high class catalogues and commercial booklets. There seems to be a bigger and a richer

field for process work over there because everybody reads something, and everything readable seems to be illustrated. Advertisers spend money lavishly on process work, because they find it brings business. It is the commercial process work that pays in America, the purely art work is almost non-existent. The artist who is prepared to forsake the orthodox paths of art, and use his brush in the service of commerce can make money, and his brother of the quill who can write prose or poetry in praise of canned pork and beans, or other delectable commodity, will also find the dollars come to him easily. It used to be said of an English publishing house that they kept "tame artists and docile literary men" on the premises in little rabbit hutches; and the American firms have carried this sort of organisation to a great degree of perfection. I must confess my admiration for the way in which the art of "making things pay" has been developed in America. They do not seem to get better prices for their photo-engraving, and they pay more than double the wages we do, whilst rent and other expenses are higher than with us. How is it, then, that they seem to thrive well? I can only conceive that it is because they make a much bigger output in a much less time, and with a smaller staff than our firms do. There appears to be no waste time in an American shop. There is no "hustling," as we understand it, but the work goes smoothly and steadily on, passing from one department to the other, and the "business end" never lets it rest until it is out and in the customer's hands. Every man must keep up with the procession, or fall out of it, and keep out. I noticed that most of the hands in American photo-engraving shops were young men, or comparatively young men, and I asked what became of the old ones. "Oh, they generally go out of the business into something else when they can't keep up," was the reply. From which it may be imagined the lot of the American photo-engraver is not an easy one.

WILLIAM GAMBLE.

[The above notes conclude the account of photo-engravers' methods in the States commenced in our issue of the 11th inst. -ED. B.J.P.]

THE DARMSTADT CONGRESS.

THIS Conference, which commenced on August 15, and closes on the 27th, is being held in the Town Hall, Darmstadt. An account of the official formalities, reception, conversation, excursions, etc., although pleasant enough in themselves, is not of so much interest to readers of the BRITISH JOURNAL OF PHOTOGRAPHY as a brief report of new apparatus and other exhibits, so no further mention will be made of these functions.

New Apparatus.

The exhibition of new apparatus, etc., is not very large. E. Merck has a display of chemicals, and also of tablets and cartridges; Goerz and Zeiss are the only important lens makers represented. The latter firm show a new Palinos "Universal" camera. This has a bed that drops in the usual way to permit of the use of a wide-angle lens. It has no focal plane shutter as with the Zeiss Palinos camera known in England, but a between-lens shutter. The Zeiss Telephoto Attachment, and the Stereo-Palinos are likewise new introductions. A new film-pack is also shown by this firm. It is new in the way each film is sold in its own dark slide ready to be put into the camera. This slide is made of black paper. A special adapter is necessary, the ground glass of which is pushed back by the slide on the American principle. The films cost but a little more than roll-films, and the film-holders can be used more than once if desired. The films are Lumière and Agfa. This firm also shows a new folding camera without a focal plane shutter and a small stereoscopic folding camera, together with a stereoscope with short focus lenses, called the Double-Verant, which corrects the distortion of perspective in a picture made with the camera pointing upwards in a most remarkable way.

With a couple of minor exceptions the manufacturers of and dealers in goods for the amateur were not represented at all. This may have been due in part to the position of Darmstadt, which is on the border of the Empire; but the days of large exhibitions are

probably passed now that the Press brings the latest news and novelties before its readers so cheaply and quickly and satisfactorily.

The portrait photographer who has a high reputation for turning out artistic work, and a clientèle willing to pay for it, is still able to stick to his legitimate profession, but the majority of photographers in all countries are now being crowded on one side by the amateur who makes portraits and groups of his friends, and on the other by the wholesale production of cheap illustrated postcards; and there is nothing to be done but to adapt himself to the new conditions by selling materials to the amateur and developing and printing for him, and by producing and selling his own postcards. Germany is the native land of the postcard, and it was a significant fact that although there was not a single studio camera exhibited, there were half a dozen machines shown for the rapid production of postcards and other bromide prints. These machines, varied in price from 50s. to £15. They were all intended to be worked by hand by the professional photographer, and some of them could turn out several hundred prints an hour. They were made by the Gekawerke in Hanau (London agent, Staley and Co., of 19, Thavies Inn, Holborn Circus), by Gamber, Drehl and Co., Heidelberg, and by Alfred Brückner, Rabenau, by Dresden. The essential feature of the Geka Copying Apparatus is a rotating disc with two windows which serve as printing frames, and two corresponding openings underneath, one having red glass and the other white ground glass. The lamp is incandescent (methylated spirits or gas). The apparatus is used in the dark room, and cut bromide paper is employed. The red glass allows the operator to adjust paper and negative and vignette quickly and easily. Then the disc is rotated in $\frac{1}{2}$ to 1 second, by the white window back to its original position, when the paper is removed and a fresh piece inserted. For the slower chloride gas-light papers both printing-windows are used, one print being exposed while another is being put in. The machine is intended to fill the gap between the large machines using bromide

rolls and making prints by the thousand, and the ordinary print by hand in the usual way.

Artificial Light for the Studio.

Herr Hofphotograph Schmidt, Kaiserstrasse 11, Frankfurt, exhibits a very ingenious electric light for the studio. The light consisted of a reflector with a row of glow lamps and a double arc lamp in the centre. The novelty in the apparatus is in the arrangement for sending a very high-potential current through the lamps in the space of a fiftieth of a second, which gives a flash of such brilliancy that a full exposure is obtained. There is no noise, explosion, no singing of the arc light. The effect is exactly that of a flash of lightning in a well-lighted room, and the exposure is so short that the most fleeting expressions are caught. There is also a considerable saving in bills; for instance, one photographer and his monthly bill reduced from £2 to 6s. The carbons are specially prepared with a core of a salt of aluminium to increase the actinic power of the light. The chief trouble with the lamp is to be that it is difficult to convince the electric light companies of the truth of the statement of the inventor, who is an amateur electrician of great ability, that this powerful current does not injure the apparatus or circuit, because it lasts such a short time.

Another photographer with a hobby is Herr Friederich Broder, of Brandenburg, who has determined to find out all there is to know about flash-lights. This year he sent off ten of his electric contact flash-light lamps one after another in a total of less than 2 seconds. He showed some interesting pictures of the length of time required by various persons to press a ball after a signal was given, and stated that a flash-light does not burn so fast as is usually thought, the time varying but little with the amount of wood burned—between 0.15 and 0.2 seconds.

Only two new photographic papers were read, but both were very interesting.

Pinatype.

The first was on Pinatype, the new three-colour process (BRITISH JOURNAL OF PHOTOGRAPHY, October 14 and 21, 1904), demonstrated by Dr. König, of the Höchst Dye Works. Three negatives are made on usual behind coloured screens. From these three transparencies are made. From the latter three so-called printing plates are made. These are glass plates coated with bichromated gelatine without pigment. The gelatine remains soft where not exposed to the light—that is, in the shadows of the transparency, and becomes hard in the lights. It is then put into one of the three colours washed and then pressed upon a piece of paper coated with gelatine, to which it gives its colouring matter from the unexposed soft gelatine, leaving the light parts pure and white. The three colours are printed on to its one gelatine film, which is the novelty of the new method. Registration is very simple, and when the bother of making nine plates is over, the subsequent printing is very simple. The dyes used are permanent to light. The actual printing is done mechanically without light, and the process can also be used to make monochrome prints, for which purpose it is only necessary to make an ordinary single negative and transparency, and from the latter a printing-plate. From this any number of prints in any desired colour can be made by mere contact with the transfer paper.

A New Carbon Process.

The other paper described direct printing carbon paper to be developed in water without the use of sawdust, which preserves all the fine details, gradations, and half-tones. It can also be printed without a photometer. The paper was demonstrated by no less an authority than Professor Schmidt of Karlsruhe, who was very enthusiastic about it. The paper is prepared by putting a plain gelatine film on first, and over this a very thin layer of gelatine containing the pigment. It is sensitised in 2 per cent. bichromate, and developed by putting it into cold water and then warm, followed by a shower from a fine spray. It is then put into an alum bath and finally into a water-varnish and dried. A great many prints were exhibited by the makers, Emil Bühler, of Schriesheim. It is not yet on the market, but anyone interested can get samples by writing to the maker. The prints are perfectly matt and fine-grained, with all details and half-tones preserved. They do not have the rich, plastic appearance of the transfer carbon paper or the coarse-grain and washed-out look of the gum bichromate print.

An Exhibition of Photographs.

In connection with the Congress an exhibition of photographs was held under the patronage of the Grand Duke of Hessen, who gave two prizes, and opened the exhibition. It consisted chiefly of professional portraits and views, but there was an amateur exhibition, and a third group of competitors for a number of trade prizes offered by manufacturers and others to assistants and photographers in a small way of business. The pictures in this group did not rise above the common-place, but Prof. Bruno Meyer, in a masterly, critical report of the exhibition, stated that a competition of this sort attracted exhibitors who would not venture to test their strength with the masters of portraiture, and this resulted in a steady improvement from year to year.

Of the professional portrait work some small carbon portraits by Grienwaldt of Bremen were very pleasing. They depended for their effect upon nothing more than in making use of this finest of all the photographic processes in a perfectly normal manner with regard to posing, background, lighting, and framing. The jury that judged the pictures placed him directly after the two German masters Dührkoop of Hamburg, and Perscheid of Leipzig, who both exhibited some fine work. One of Perscheid's portraits may be taken as an example of a class of work very largely represented at the exhibition. It was a print on brown carbon paper with a canvas surface, varnished, made from a paper negative enlargement, and framed in a large black frame. One was struck at once upon entering the exhibition with the number of dark-brown large portraits in dismal heavy black frames that might have been cut out of an old, dark rosewood piano-case.

A second style that was exhibited by several photographers consisted of a small print mounted on a large dark-tinted mount, perhaps 16 by 22 in., glazed and framed in a narrow frame of natural oak, black or old gold; the print was seldom mounted in the middle of the mount, and was sometimes mounted first on a white or lighter tinted paper, leaving a narrow border. One mount appeared to be made of green felt such as is used to make Tyrolean outing suits; another was an ordinary bookbinder's board; and another, by Dührkoop—one of the prettiest pictures in the exhibition—was ordinary parchment paper on which a portrait of a lady in warm black platinum was mounted. There were a few pictures framed in the modern style of frame, with the top, bottom, and sides different. Frames of this sort claim a part of one's attention as a work of art in themselves, but if one's attention is to be so distracted from the picture, it is pleasanter to find the frame pretty rather than with the air of having been borrowed from a chromo in a country inn. A picture that would attract attention in a reception room or show-case was a large carbon print of the head of a collie-dog by Richter of Elberfeld.

Three-colour Work

An interesting collection of three-colour pictures was shown by the Neue Photographische Gesellschaft of Berlin-Steglitz. Among these was one of a lady in a dress covered with flowers, who, as Professor Bruno Meyer said, would have been the despair of the ordinary photographer. In this three-colour work, he said, lay the chance for the artistic photographer to produce work that cannot by any possibility be done on a large scale and cheaply. At the same time, he added, one must bear in mind the limitations of the process, since the more beautiful and delicate tints of some of the single pigments cannot be reproduced by mixing the three primary colours—a remark which leads one to wonder whether the three-coloured processes are destined to replace the handcoloured ordinary portraits. However, the effect of these coloured pictures was very striking. One was a still-life picture in which the red of a lobster, the delicate brown of a roll, the green of a champagne bottle, and the colours of some flowers were all reproduced very exactly.

Other Exhibits.

Professor von Jan had some interesting wave pictures, enlargements in green carbon paper, and Götz of Breslau some fine landscapes, enlargements on green gum-bichromate. Krauth of Frankfurt had a fine green carbon picture of two girls on a sofa, and Paetzmann of Dresden had two somewhat similar, one in black with a small matt frame to match of a girl in a satin dress, the other a dark-brown portrait of a girl in profile, with subdued lighting, with a brown frame. There were several portraits of girls on sofas in the exhibition, which were all very pretty. Freiherr von Schlippenberg of Dresden exhibited a landscape that showed the influence of Böcklin, a painter more admired by his countrymen than by foreigners, and also a gum-bichromate study of a head framed in the only black frame of the exhibition that appeared to me to be artistic. It was not so much a frame as a plain square piece of board finished in the piano-case polish referred to above, with an elliptical piece cut out of the middle and moulded in a moulding machine.

Bähr of Dresden, a member of the self-styled Photo-secession, showed an interesting bromide print of a winter landscape with the skyline above and outside the picture, framed in a white frame, of which there were too few in the exhibition to relieve the funereal sombreness of the black frames; and finally the combined School for Photography and Painting in Dresden showed a couple of allegorical pictures in modern frames which combined the two arts with such artistic feeling that one did not notice when the photograph stopped and the painting began. I find that I have said nothing about the backgrounds used, which is perhaps sufficient praise in itself. They were either plain, shaded here and there to set off the tones of the portrait, or they hinted at a panelled wall or an interior without attracting attention.

In closing this report I should like to express my thanks to the genial President of the Association, Herr Schwier, for the kindness and hospitality shown to me by him and many of the other members.

W. D. DAVENPORT.

BRITISH GOODS ON THE CONTINENT.

An Open Letter from Italy.

[We have received the following communication from a correspondent in Genoa, and, while not altogether agreeing with everything he says, cannot deny there is a deal of truth in his statements and soundness in his suggestions.—Eds., B.J.P.]

"Having been many years on the Continent, I am struck by the comparative obscurity into which British photographic products have sunk, and firmly believe this is largely due to the British manufacturer himself.

"He thinks that 'foreigners' ought to conform to his ideas, and if they won't, he leaves them well alone. Having been left alone some time, they have naturally bought other makes, and it will be difficult for the lost ground to be regained if more 'leaving alone' is continued. It may be won back without great difficulty as yet, and I am trying to point out some stumbling blocks in the way.

"I have been in Germany, France, Switzerland, and Italy, and have bought photographic supplies in these countries, and mention this to show that I do know something about the subject. Of these four countries three are full of advantages to the British manufacturer—Switzerland, France, and Italy; the two last especially so.

The Populer Camera.

"Frenchmen and Italians like a light, smart-looking camera, which ought to have a really good lens of sharp definition; and if there are rising fronts both ways so much the better, for amateurs are becoming aware of the necessity of this movement. The cameras ought to be built for the 9 x 12 cm. size, universally used over the whole Continent of Europe, and will then command a ready sale (which is not the case with the squarish quarter-plate the British manufacturer persists in sending out), for this plate is growing into greater favour every day, on account of its elegant proportion and convenient size. Such a camera, neat, tasty, wearing well, and capable of fine work, should cost about 60 francs with a good rapid rectilinear and T.I. variable speed shutters, together with slides for six plates. Camera and slides ought not to weigh more than 1.5 kg., and compactness is very necessary, far more so than in England.

Advertise, Advertise.

"But one point should not be neglected, as it is now: I refer to advertising. Advertisements of British makes are *rare ayes* in Continental photographic papers. In Italy, the note that the goods advertised are of 'Fabbricazione inglese' will draw the public, but for France some discretion must be exercised in the use of this note, though the 'entente cordiale' has prepared Frenchmen to lend a friendly eye to such announcements. A profusion of smart show-cards in the dealers' windows will be a great help, and the advantage of a rising front ought to be illustrated. The camera will then be quickly bought, and another order will ensue if the qualities it is stated to possess are proved to be actual.

Formulæ for the Continent.

"Plates and chemicals. The 'foreigner' is not so enthusiastic a photographer (generally speaking) as the Britisher, and I strongly recommend that the developing formulæ the British manufacturer pastes on his plate boxes be discarded, as they are rarely read, for few 'foreigners' know English, and when they do the effect is rather unfavourable than otherwise. I have known instances when people have refused to buy plates, because the maker said that best results were obtainable with the formulæ given. Now, everyone starts with the idea of getting best results, and few care to make up the formulæ. Sometimes the British manufacturer gets his instructions printed in the foreign language, and they then are often apt to bring a grin on the foreigner's face as he peruses them. Print the label in good

modern French (both for France and Italy), and leave out the developing instructions.

Developers.

"Few amateurs here compound their own developers, etc. They like the little packets, tablets, powders, and wee bottles German enterprise sends them, with instructions in their own language as to the number of cubic centimetres of water required to make a bath. I suppose such little packets, tablets, powders, and wee bottles are not made by the British manufacturer, or is the burden of supplying the British public so great as to prevent his giving a thought to the 'foreigner'? I do hope if he does deign to send more scraps down here, he will be so kind as to give instructions as to dilution in French and Italian (for the respective countries). By the way, minims, drachms, liquid ounces, apothecaries' weight, troy, etc., etc., are quite unknown to the 'poor foreigner.' He has been taught that a litre contains 10 decilitres, 100 centilitres, and 1,000 millilitres. This last is a cubic centimetre, and it is generally said that a litre contains 1,000 cubic centimetres. The foreigner also knows that a cubic centimetre of water at 4 deg. centigrade (pure distilled water) weighs 1 gramme, and that a litre contains 1,000 cubic centimetres, weighing 1 kilo. A centimetre is the 100th part of a metre. Having such a childishly simple system of weights and measures, applicable with equal facility to the finest operations of chemistry as to the weighing of groceries, it is not surprising that the foreigner looks with dismay at the extraordinary medley of measurements from England. Let the British manufacturer send out his products with instructions in French and Italian as to metrical dilution, supporting this with advertising and show cards. He will not repent it if the chemicals are good and cheap. Pyro developer is not popular on the Continent among amateurs. Quinol, metol-quinol, metol, and paramidophenol are mostly used. A 60 cm. bath is the thing for 9 x 12 cm. plates, and 100 cm. for 13 x 18 cm. plates. If a packet or tablet for 60 cm. solution can be retailed to foreign amateurs for 15 centimes (1s. 0½d.), a very large sale ought to ensue, for similar products of other makes are somewhat dearer. Of course, the solution must be full strength, and capable of further dilution if necessary.

Other Materials.

"Acid hypo baths are coming into use, and should be provided for. A large proportion of Continental amateurs use no paper but P.O.P., and the combined toner and fixer is the only one they care for. They generally complain of its cost, and, if moderately-priced combined baths in powder or tablet form can be placed on the market, there is nothing to prevent their coming into favour. The long instructions about toning and fixing should be omitted, and simple directions as to the use of a combined bath given. Papers which do not admit of ordinary combined baths being used had better not be sent out.

Suggested Co-operation.

"The British manufacturer would have a large part of the trade in France and Italy were he to combine with his brother makers (of cameras, plates, films, papers, chemicals) to establish a general dépôt at Paris for France, and at Milan and Naples for Italy. Through these dépôts he can reach every part of the country. These dépôts should alone be in touch with the dealers all over the country, sending them the goods ordered, and catalogues, leaflets, show cards—all these in the language of the country—looking after the advertising, which ought to be done on a lavish scale. If British prices can be maintained with home quality, sales will soon follow after a year's tentative buying on the part of the dealers. Perhaps plates can be sold at a somewhat higher rate, for, as a rule, British plates are very cheap, compared with Continental ones. Special rapid first quality plates at 2 francs the dozen will sell like hot cakes.

"I repeat that the establishment of such dépôts by a number of first-class makers combined cannot fail to succeed. The managers ought to be British, and have a thorough knowledge of the language they must needs use with the dealers and the public. As the expenses will be divided among several large firms, they will not be oppressive, and the profits will be relatively greater, as the prices will not have been lowered.

"ITINERANT BRITON."

LADIES AS PHOTOGRAPHERS.

An article bearing the above title the "Daily Telegraph" for Saturday last deals at length with the skill and success of Queen Alexandra, Princess Charles of Denmark, Princess Victoria, Princess Henry of Battenberg, and other members of the Royal Family clever picture-makers with the camera. Her Majesty has made some notable additions to her photographic record of historic scenes during the recent visit of the French fleet. Princess Henry has also added her camera on the Sheila, her own little yacht, which has been moving about a good deal during the memorable week, and the royal photographer, who has the advantage of being an artist, has taken some excellent pictures of the splendid sea pageant.

The Queen is rarely without her camera, which, by the way, is Kodak, and, as mentioned in last week's "Ex Cathedra," it is by no means uncommon for the irrepressible, so-called "camera fiend," while imagining himself securing a surreptitious "snapshot" of his sovereign's consort, to find himself in turn under Royal "fire." A case of this kind occurred when the Queen was staying at Lismore Castle. Most of the party were salmon-fishing, and her Majesty, with her camera, wandered off along a picturesque creek. Here an artist, also much interested in photography, was waiting, and, seeing the great lady approaching, devoted himself to locating her in his view-finder. What was his surprise, on looking up after "pressing the button," to discover that he, in the amusing posture assumed in his excitement, had just made an impression on one of her Majesty's films. Few notable scenes at which Queen Alexandra has been present have been left unrecorded in this way, and it is doubtful whether any more interesting and instructive collection exists than that which she has herself made.

The example set by her Majesty "in taking up photography as a hobby," says the "Telegraph," "has been followed by thousands of other ladies, who in enthusiasm and skill equal, if they do not surpass, men in the art. To the fair sex at every exhibition a large proportion of the prizes invariably are allotted. Especially is it interesting to note the class of subject to which they, as a rule, are most appropriately attracted. Their cameras seem to turn intuitively towards home life. 'The Old Thatched Cottage,' 'Youth and Age,' as depicted by the grandmother and her chubby, curly-headed descendant, are representative types of what the feminine photographer appears most to love. True, there is the lady Alpine climber, like Mrs. Le Blonde, on the one hand, who revels in snow-capped peaks peering through sweeping mists, and, on the other, the aesthete who lingers with joy on the view of a single graceful flower spray. Altogether, women show a remarkable daintiness of selection in what they do photographically as in other respects, because daintiness and refinement are essentially more prominent in them than in man. For its development, it must be confessed, much is due to the hand camera. It has, perhaps, educated a closer study of the beautiful in the ordinary surroundings of everyday life than anything else. Not every woman has had an opportunity of art training. But all who possess cameras must, consciously or unconsciously, undergo a certain amount of that education they otherwise might have lacked. As they proceed they must find that to be successful they must study composition and colour, although the reproduction will be in monotone. They must be continually on the look-out for what is artistically best in the scenes through which they pass. Lectures on art may do a great deal, but constant occasion to put art principles into practice will do infinitely more. The hideous old oleograph has passed away for ever, and its place has been taken by pictures infinitely better. In the last twenty years the general standard of public taste has risen at a marvellous rate, and its advance has, curiously enough, been coincident with the improvement of photographic apparatus."

PROPERTY IN PHOTOGRAPHS.

In the "Daily Chronicle" of Friday last appears a reply to the letter sent to that paper by the Secretary of the Photographic Copyright Union in reference to the Crooke-Irving case. We were also asked to publish this letter, a copy of which appeared in our last issue. The communication published in the "Daily Chronicle" is from Mr. Clement Shorter, who says:—"Will you permit me to say in reference to the circular issued by the Photographic Copyright Union that the whole of their criticism is based upon a misreport of what I said to an interviewer. In the first place, I did not describe photographers as robbers, the word having been used in a very limited sense, and many of these gentlemen being good friends of mine. In the second place I did not say that 'the history of the photograph was coincident with the process block.'"

"I was fully aware of the large sums of money that have been secured by photographers through the sale of photographs in the days before they were widely used in illustrated journals, but what I did urge was that the history of the photograph for the purposes of newspaper illustration was coincident with the process block, and I contended that the illustrated newspaper has given an enormous impetus to the commercial aspects of photography. Whereas in the old days large sums of money were made from the sale in shops of photographic prints of a popular politician or actress, to-day far larger sums of money are made from the sale of quite undistinguished people and incidents which involve scarcely any trouble whatever to photograph, and are of the most temporary value. All of these are now used not only in illustrated newspapers, but in the form of postcards, books, and a hundred and one methods of mechanical reproduction, which places the photographer of to-day in a vastly better position than he was a generation ago, when he was at the mercy of the man who bought a dozen cabinet portraits or cartes-de-visites. This change for the benefit of the photographer is almost entirely due to the existence of the illustrated newspaper."

An editorial note which follows Mr. Shorter's letter states:—"The interview with Mr. Shorter appeared in the "Daily Chronicle" on July 8, and no communication concerning a 'misreport' has been sent to us until now."

Mr. Shorter may be an extremely busy man, but we think it strange that until the matter has been given such extensive publicity he has not taken the trouble to acquaint the Editor of the "Chronicle" with the fact that he was "misreported."

PHOTOGRAPHER to her Majesty.—Her Majesty the Queen has honoured Mr. W. S. Stuart, of 2, The Quadrant, Richmond, with a warrant of appointment as "Photographer in Ordinary" to her Majesty. Mr. Stuart now holds seven Royal warrants, and three of these, viz., to her Majesty the Queen, H.M. the King of Spain, and H.M. the King of Portugal, have been granted within the last six months.

THE Coming Solar Eclipse.—A Reuter telegram from Madrid to the "Times," dated August 19, states that the British astronomers who have come to Spain for the solar eclipse will make their observations from Albocacer, between Vinaroz and Castellon.

THE Rotary Photographic Company, of 12, New Union Street, Moorfields, request us to inform the honorary secretaries of all photographic societies that they are prepared, as in previous years, to give demonstrations, not only of the use and manipulation of their various products, but also of their system of natural colour photography. Further, that early application is desirable, as their list of vacant dates is fast filling up.

Photo-Mechanical Notes.

An Antidote for Nitrous-Vapour Poisoning.

ZINC-ETCHERS, who have to spend a good deal of time under conditions in which it is difficult to avoid the inhalation of the nitrous fumes arising from the etching bath, may be glad to note an appendix to the report of H.M. Inspector of Explosives, in which an account is given of experiments made on chloroform as an antidote for the severer form of poisoning which is caused by the gases arising from exploded dynamite:—

"At a meeting of the Johannesburg Chemical and Metallurgical Society (Transvaal), Eric Weiskopf spoke on antidotes for poisoning by the gases arising from exploded dynamite. It was a matter of frequent observation in nitric acid factories that after inhaling nitrous vapours a man may feel perfectly well, but may be afterwards seized with fatal convulsions, and as a reason for this he advanced the view that the nitric produced by the explosion was oxidised in the blood to nitrous acid. He had found that three to five drops of chloroform in a glass of water, administered as a drink every ten minutes, formed a good antidote. Dr. Seyferth, Director of Troisdorf Powder Factory, near Cologne, considers the foregoing explanation of the action of chloroform taken internally as incorrect, and explains it as follows:—The convulsions which sometimes supervene after inhalation of nitrous or nitric vapours should be considered as a reflex action caused by the inhaled vapours setting up an irritation of the very highly sensitive motor nerve endings in the respiratory region. The convulsions effect the heart, lungs, and diaphragm—the vital organs, in short—and ultimately death follows. The effect obtained by E. Weiskopf, when chloroform is taken internally, follows from its well-known property of preventing or diminishing such a convulsive condition as is brought about by any means of stimulating a tetanising reflex action. According to the new edition of the Pharmacopœia Germanica III., the maximum single dose of chloroform (kept carefully from the action of light) is 0.5 gramme, and the maximum daily dose is 1.5 gramme. Special weighings show that the weight of three drops of chloroform is 0.045 gramme, and of five drops is 0.073 gramme, so that, following the Pharmacopœia, 33 doses of three drops or 18 doses of five drops may be administered in one day without danger to the workman. To prevent misuse or overdose of chloroform the following procedure is recommended: In every acid factory there are to be kept under a glass bell jar three dropping vessels of dark glass, each containing 0.5 gramme chloroform. In the event of an accident, therefore, neither the maximum single dose nor the maximum daily dose should be exceeded. The authorities of the Troisdorf Powder Factory have issued the following factory notice to their workmen: After inhaling nitrous gases, a man may feel perfectly well, though afterwards convulsions that may prove fatal are liable to follow. The following regulations are, therefore, made to prevent accidents; officials and workmen are directed to follow them implicitly. In the event of such an accident as the breaking of a bottle of nitric acid, should any one inhale the nitrous vapours, the foreman or person officially in charge shall make it his duty to administer to the person so attacked doses every ten minutes of three to five drops of chloroform, delivered from a dropping glass into a tumbler with water, since this drink has proved a valuable antidote. For this special purpose there are kept in the house under a bell jar a tumbler and three dropping glasses made of dark-coloured glass, each dropping glass containing 0.5 gramme chloroform. According to the Pharmacopœia (Germanica), the maximum single dose of chloroform is only 0.5 gramme, or the contents of one dropping glass; the maximum daily dose is 1.5 gramme, or the contents of three dropping glasses. Three drops of chloroform weigh 0.045 gramme, five drops weigh 0.073 gramme. It should be noted

that each dropping glass has a seal which must be broken before the chloroform is used."

Mounting Collotype Plates.

A design of moistening cylinder for collotype presses has been patented by Carl Wagner and F. Strange, of Berlin (Eng. Pat. No. 26,105, 1904), who advance it as extremely compact, and thus applicable to existing machines, to permit of printing equally large formes as previously. The arrangement consists of several cylinders near the printing cylinder seated in side bearing blocks formed correspondingly to the roundness of the printing cylinder, and so that they can be raised therefrom, the moisture being conveyed from the flannel or felt-covered cylinder through the medium of two cylinders, by which it is uniformly distributed over the printing plate.

Etched Plates without a Screen.

A German patent has been granted to E. Spitzer, of Munich, for a process in which the half-tone or grain screen is dispensed with in preparing an etched plate. A print is taken direct, from an ordinary half-tone negative or transparency on to a grainless sensitive printing plate, and this print exposed to the etching medium without the film being burnt in. Asphalt powder is then dusted on and melted in, the print thereby becoming more or less permeated by the etching fluid. It is thus etched not only in the unexposed but also in the exposed portions. Fine etching is applied in the process, the above description of which obviously needs supplementing with more detailed explanation of how a sufficient etched printing surface is obtained.

A Chemical Graining Process.

According to the process of Herr P. Glaser, of Leipzig, by whom a patent has been taken out, any surface to be grained is exposed to the vapours of substances which will unite with a substratum on the surface to form a grain. For example, a silvered glass or metal plate is exposed to iodine vapours, the silver being converted into silver iodide, which is sensitive to light, and is subsequently exposed under a negative or positive transparency. It is then exposed to mercury vapour, fixed, and, if necessary, gilded. The grain can be easily etched into glass with hydrofluoric acid.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes.

The following applications for patents were made between August 8-12, 1905:—

COLOUR PHOTOGRAPHY.—No. 16,104. "Improvements in colour photography." William Norman Lascelles Davidson, 20, Middle Street, Brighton.

DEVELOPING DISH.—No. 16,111. "An improved form of dish or tray for developing photographic images on rigid supports." Joseph Hutchinson, 119, Turner Lane, Ashton-under-Lyne, Lancs.

SENSITISING DYES.—No. 16,227. "Manufacture of blue colouring matters of the quinoline group and photographic surfaces sensitised therewith." Oliver Imray, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London. (Farbwerke vormals Meister, Lucius und Brüning, Germany.)

CHANGING BOX.—No. 16,390. "Improvements in photographic changing boxes." Arthur Richard Kellaway Jeffery, 37, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

INSTANTANEOUS SHUTTERS.—No. 20,327, 1904. This is an improvement on the well-known roller blind instantaneous shutters, by means of which all the operative parts are enclosed in the shutter

box, and mounted upon the sides of the same. The Thornton Pickard Manufacturing Company, Limited, Altrincham, Chester; George Arthur Pickard and Frank Slinger.

PNEUMATIC BALLS.—No. 20,330, 1904. This is an appliance for application to the pneumatic ball of photographic shutters, constructed with two plate levers or the like pivoted or flexibly connected together, by means of which pressure may be applied to the ball; the idea is to ensure more even and regular results, and to obviate the difference in the amount of compression, causing a different amount of air to be expelled when used by different operators; thus ensuring more regularity in the duration of exposure when an adjustable air escape valve is employed. The Thornton Pickard Manufacturing Company, Limited, of Altrincham, Chester, and George Arthur Pickard.

PHOTO-PRINTING APPARATUS.—No. 20,386, 1904. This invention relates to improvements in photo-printing apparatus of the kind described in the Specification to Letters Patent dated October 21, 1902, No. 22,941, wherein the tracing or other transparency constituting the "negative," backed by a sheet of sensitive paper and a covering apron, is conducted round the surface of a glass plate of cylindrical form, in the focal axis of which works an electric lamp or other suitable light-yielding appliance. The primary objects of the present invention are to provide mechanical means, first, for driving the feed-rollers which actuate the covering apron and work the negative and the sensitive paper over the surface of the glass plate or printing table; and, secondly, for automatically lowering and raising the electric lamp during the printing operation, the means for accomplishing the latter object being also applicable to photo-printing apparatus of the ordinary type in which the negative, the sensitive paper, and the covering paper are stationary. Leonard Shaw, 39, Victoria Street, Westminster.

New Materials.

Ensignol. A new developer, sold by Houghtons Limited, 88 and 89, High Holborn, W.C.

The claims made for this new developer are that it is vigorous, clean, and economical. In these respects we find it very similar in action to Amidol, which it resembles somewhat in appearance. Normally exposed plates, or films, are fully developed in two or three minutes, the time of first appearance being very short. With bromide and gaslight papers very fine black tones are obtainable, and the simplicity with which the developer can be made up for use is in its favour. The normal developer is made up by dissolving 2½ oz. of crystallised sulphite of soda in 30 oz. of water, and then adding ¼ oz. of "Ensignol." This solution can be used repeatedly, and does not discolour even after prolonged exposure to the air.

The negatives obtained are of a clean bright character and a good black and white quick-printing quality. For bromide papers it will be found advantageous to dilute the developer with an equal bulk of water and to add a few drops of potassium bromide, 10 per cent. solution, otherwise the action is very rapid, and cannot be kept under control. We can recommend this developer as being at once economical and reliable.

"Platinochrom," a "Self-Developing" Platinum Paper. Sold by O. Sichel and Co., 52, Bunhill Row, London, E.C.

The novelty of this paper lies in the fact that although treated in exactly the same way as ordinary platinum paper up to the completion of printing, it does not require to be developed in the

usual manner in an oxalate solution. The prints, after being taken from the printing frame, are placed on one side in a damp atmosphere, and development takes place automatically without further attention. If it is desired to hasten matters, the prints can be held over the steam from a kettle of boiling water, when they will promptly develop out to full density. Even breathing on the prints will effect development, and in this way, by directing the breath through a short tube, some excellent vignetting effects can be obtained, or local development can be resorted to. The prints are fixed by washing in a weak solution of common salt (10 per cent.) or in water to which a few drops of hydrochloric acid have been added. Fixing is complete when all yellowness has disappeared from the paper, and a final rinse completes the process. If a packet of the paper has been open for some time, and the paper has taken up moisture from the air before being put in the printing frame, and it will then print right out. Sepia, red chalk, blue and green tones can also be obtained by employing the toning baths recommended by the makers. The new platinum paper should be very popular in view of its extreme ease and simplicity of working. It is not expensive.

Haystack P.O.P. Made by the E. F. Stack Manufacturing Company, Leyton, Essex.

We have received samples of this latest claimant for notice among P.O.P. users, and find on trial that it possesses characteristics that point to its usefulness during the darkening days of the forthcoming autumn. We refer to its quick printing qualities, and equally rapid ease of toning. The emulsion is rich in silver, and the paper appears to be carefully prepared and very evenly coated. Double toning with any of the usual sulphocyanide toning baths is conspicuous by its absence. Good tones are given by a combined bath, recommended by the makers, but this we do not advocate on the score of permanency. With a concentrated phosphate and borax bath brush-toning can be carried out with effect, and the resultant tones are very even. A noteworthy feature of the paper, as sent out by the makers, is the careful method of packing, every care being taken to keep the sheets from exposure to the air. The paper is supplied in the usual cut sizes, and is somewhat cheaper than the other makes on the market. Samples will be sent on application enclosing a stamp for postage. We understand that the makers are presenting handsome little gold and enamel brooches to the collectors of certain numbers of the coupons enclosed with each packet of the paper.

CATALOGUES AND TRADE NOTICES.

RECEIVED.—From Houghtons, Ltd., 88 and 89, High Holborn, W.C., "The Cherrill Printing Frame for Pictorial Photographers." From Messrs. Chas. Zimmermann and Co., 9 and 10, St. Mary-at-Hill, London, E.C., "The Agfa Chromo Plate." Reports dealing with these novelties will appear in an early issue.

FOR Observing the Eclipse.—From Messrs. R. and J. Beck, Ltd., of 68, Cornhill, we have received a useful little dark glass screen for the purpose of viewing the sun during the eclipse on August 30. It is well and conveniently made for holding close to the eyes, and the sun, when seen through it, appears of a dull golden colour. The price of the screen is 1s., or post free 1s. 3d. It is a useful little piece of apparatus to have for solar observations at any time.

SOME attractive little circulars have been issued by Messrs. J. J. Griffin and Sons, of 20-26, Sardinia Street, Lincoln's Inn Fields, W.C., dealing with their well-known "Professional P.O.P." Hints as to the manipulation of the paper and other useful information and instruction are included in the leaflet, copies of which will be distributed to any of our readers on application.

A **TRADE** price list of photographic work has been issued by Percy J. Slater, of Sawtry, Peterborough. Prices for printing, toning,

mounting, copying, and enlargements are given, while developing, intensifying, and reducing, and making postcards from customers' negatives are also undertaken. Mr. Slater's prices compare very favourably with those of any in the trade.

"THE WELLINGTON" price list deals with the latest products of the famous Elstree firm, and contains particulars and prices of all grades of Wellington papers, plates, and films. Every photographer should write for a copy.

THE name of the Photochrom Company, Ltd., of Hosier Lane, Snow Hill, E.C., is associated with their photochrom work to such an extent that the fact is very often overlooked that they have every facility for the production of high-class half-tone blocks and three-colour work. The firm is making a special feature of their process department at the present time, and are securing excellent results. A postcard will bring full particulars.

Commercial & Legal Intelligence

PHOTOLINOL, LIMITED (LONDON).—Re-issue on July 20 of £200 debentures, part of a series created March 20, 1905, to secure £3,000, charged on the company's undertaking and property, present and future. No trustees. Total amount previously issued of same series, £1,700.

THE BURGLARY AT HOUGHTONS.—Walter Edward Sochon, a well-dressed youth of 19, who was said to have only just got married, and resident at Albion Road, Dalston, was charged at North London Police-court on Thursday of last week with breaking into a warehouse at Tudor Road, Hackney, and stealing 14 photographic cameras, worth £48, the property of Messrs. Houghtons, Limited, of Tudor Road, Hackney.—One of the principals of the firm identified a camera produced by Detective-inspector Smith, and said it was worth £7; but the prisoner was detected offering it for sale for 25s.—Herbert Holmes, manager at the works, said he secured the premises at 8.30 on Tuesday, and found that a forcible entry had been made when he went to business next morning.—Mr. Ernest Hinks, of Goodmayes, near Romford, said he dealt in cycles and photographic apparatus. On Wednesday the prisoner called on him and asked him to buy the camera now in Court. Seeing at once that the camera was worth a good deal more than the 25s. asked, he detained the prisoner in conversation whilst he sent for a policeman. The prisoner said at first that he got the camera in exchange for a bicycle, but afterwards said he had it given him.—Mr. Cowper, who defended, said his client had an answer to the charge. The police opposed bail, as the prisoner had several pawntickets in his possession.—The prisoner was remanded.

SARONY AND CO., LIMITED (Photographers, Scarborough).—Issue on July 31 of £150 debentures, part of a series created May 5, 1905, to secure £4,000, charged on the company's undertaking and property, present and future, including uncalled capital and premises in Scarborough and Harrogate. Trustee: J. Pirie, Scarborough. Total amount previously issued of same series, £3,150.

PHOTO DEVELOPMENT SYNDICATE, LIMITED (Tanbridge Wells).—Issue on July 27 of £80 debentures, part of a series created July 15, 1905, to secure £500, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £420.

AN Administration Order.—At the Bournemouth County Court, Percy Reginald Street, photographer, of 21, Charminster Road, applied for an administration order. Applicant's debts amounted

to £26, which he proposed to pay in full. Debtor had filed an affidavit to the effect that his average takings were 2 gs. a week, and his expenses, including rent, 18s., leaving 24s. to keep himself, his wife, and his two children. The debtor stated that the furniture in the house belonged to his brother, and his photographic apparatus to his mother, who had given it him, but had afterwards bought it from him. The Judge made an order for the payment of the debts by instalments of £1 a month.

No Fraud.—At the Skipton Town Hall, on Monday, Henry Stephenson, described as a canvasser, of Keighley, was charged with obtaining 11s. by means of false pretences from Mrs. Alice Chew, Sandylands, Cross Hills. The prosecutor was William Knowles, photographer, Keighley, who was represented by Mr. C. P. Cass, of Keighley. The evidence showed that the defendant had been in the prosecutor's employ as canvasser from July 14 to July 29 last, and received a salary and commission on orders. Prior to leaving Knowles's employ on the 29th ult., the defendant had obtained an order from Mrs. Chew, and the prosecutor received 2s. 6d. by way of deposit. On writing to Mrs. Chew and inquiring her convenience as to a sitting, the prosecutor ascertained that the defendant had called upon her and obtained 11s. The evidence of Mrs. Chew went to show that on the previous Wednesday the defendant called upon her, and, ascertaining that she had not sat for her photograph, assured her that it would not be necessary to go to Keighley for the purpose—he would take it for her at her own house. He brought a photographer with him, and the photograph was taken. The witness asked the defendant if he was then in the employ of Mr. Knowles, and to this he replied: "I am the man who took the order, and it doesn't matter so long as I carry the order out." After the photograph had been taken, the defendant asked for the money, and the witness, knowing from his answer that he was not at that time in Mr. Knowles's employ, paid him. The Court found that there was no false pretence inasmuch as Mrs. Chew knew that the defendant was not then in Mr. Knowles's employ. Stephenson was at once discharged.

EASTMAN KODAK COMPANY OF NEW JERSEY.—The usual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding Preferred stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the Outstanding Common stock, have been declared by the Eastman Kodak Company of New Jersey, payable on October 2, 1905, to stockholders of record at the close of business on August 31, 1905.

ADVERTISING DESIGNS.—Messrs. W. H. Smith and Son have organised a special department for the production of original ideas and suggestions for designs appropriate for posters, catalogues, book covers, pamphlets, and the like. They are now holding a little exhibition in their new premises in Amberley House, Norfolk Street, Strand, of designs for posters, catalogue-covers, and other advertisement matter by several well-known artists, like Mr. John Hassall, Mr. Cecil Aldin, Mr. Lawson Wood, Mr. Lewis Baumer, Mr. Charles Dixon, M. Popini, Mr. Fred Taylor, Mr. S. E. Scott, Mr. Chas. Pears, and others. The department, which is under the control of Mr. H. E. Morgan, aims at being of real service to the man of business by telling what he wants and then supplying it; but such work as is now on view will also be of service to the public in giving them advertisements which can be looked at with pleasure. The reproductions in two-colour and three-colour and half-tone are good; in one case which came under our notice the print is even an improvement on the original drawing; and the firm has succeeded in producing one of the largest three-colour blocks ever made. It measures 20 in. by 30 in.

News and Notes.

THE South London Photographic Society are holding a conversation at Collyer Hall, High Street, Peckham, on September 4, at eight p.m., to inaugurate the new session, to which they invite anyone interested in photography. There will be music and singing, two or three lantern shows, and a number of selected pictures will be on view. Intending visitors will please write to the secretary, H. Breighton Beckett, 44, Edith Road, Peckham, when he will be pleased to send an invitation card.

THE "Kokka."—Among the many wonders of Japan not the least is the "Kokka," a monthly magazine dealing with the fine and applied arts of the Far East. Without going further in comparisons, which might seem invidious, observes the "Daily Telegraph," it may safely be said that no periodical to which the science and taste of Western civilisation have been devoted has been able to produce coloured plates or collotypes of a higher level of excellence and beauty than those which appear in the "Kokka." Nor is it by any means a novelty, for it has now been running for seventeen years. It had not been in existence long before it came to the notice of Western connoisseurs, and four years ago the experiment was tried of printing a portion of the letterpress in English. In consequence of the growth of the circulation among foreign subscribers, it has now been decided to issue a special edition, entirely written in the most widespread of the Occidental languages. The change was made in July, and the copies of the new "Kokka" for that month have now reached this country. An interesting preface declares that one of the chief objects of the English edition is to make Western nations as well acquainted with the power of Japan's arts as they already are with that of her arms. The price of the magazine is two yen a number, and the agent for its sale in Great Britain is Mr. Quarritich. It can also be obtained from the "Kokka" Company, No. 10, Yazaemon-cho, Kyobashi-Ku, Tokyo.

MESSRS. HOUGHTONS' Camera Works at Hackney were burglariously entered on the night of August 14, and a number of cameras were stolen. These included six of the more expensive models of the "Klito" camera, three Tudor cameras fitted with high-class lenses, a half-plate mahogany hand camera, and three Sanderson cameras. As all the Sandersons are numbered on the struts carrying the lens front, it is quite possible that some of our readers may be able to detect these cameras if they are offered for sale. We append the following particulars which Messrs. Houghtons have supplied:—1. Quarter-plate regular Sanderson hand camera No. 7,502, fitted with a Goerz lens; No. 1,457 on the mount. 1. Junior Sanderson hand camera quarter-plate No. 10,424, fitted with an Aldis lens; No. 1,043 in unicum shutter. 1. Quarter-plate regular Sanderson hand camera No. 10,722, fitted with a B. and L. lens in unicum shutter. If any of our readers come across one of the cameras mentioned above, we should be very glad if they would communicate with Messrs. Houghtons, Limited, 88 and 89, High Holborn, London, W.C. Some of the stolen apparatus has already been recovered, as will be seen by reference to our Legal and Commercial column.

WITH reference to our remarks in "Ex Cathedra" last week as to the risk of sending negatives by post, Houghtons, Ltd., call our attention to their Holborn negative posting box, which was reviewed by us some time back, and which we have found very efficacious and safe in use.

THE meeting for the official winding-up of the Camera Club was held on Monday last, when it was stated that over 200 members had signified their willingness to join the Blenheim Club; but the number

was still 30 short of that required to induce the Blenheim to undertake the building of the studio. Valedictory and regretful speeches were the rule, and there seemed to be a fairly general opinion that the arrangement would not be permanent, the most pessimistic giving it merely a twelvemonths' run. In response to numerous inquiries, it was stated that members desiring to acquire any of the club's property might privately approach the auctioneer; but that all members would receive an official communication as to the date of the auction.

IN an excellent article on "How I Photograph Lightning," which appears in the current issue of the "London Magazine," Mr. James Leadbetter gives the following practical hints on the same. Anyone wishing to take up this branch of the work will require a large space for his operations, from which he will be able to obtain a clear view of the heavens around him. As to the camera required, any ordinary camera will do, and the size is of no importance; stop used with the ordinary rectilinear lens, $f/11$; and use ordinary plates—backed for preference. Some prefer films, so as to avoid halation. A wide-angle lens is perhaps better, because you are more likely to get the whole of the flash, or, if two or three flashes appear together, to get them all. It is always better to hold the camera in the hand; but, in any case, it must be kept well covered to protect it from the rain, which will, of course, damage the lens. For focussing, the best method is to focus the camera on any object a mile away in the daytime, which is much less trouble than at night; and when you have done this accurately, mark the camera in such a way as to be able without difficulty to bring it into the same position. It is very important that the focussing should be sharp, otherwise, however lucky you may be in catching the flashes, your plates when they are developed will show that you have achieved nothing. As stated above, it is likewise essential that one should, if one wishes to be economical with plates, judge as nearly as possible the spot at which the flash is due to appear by observing the direction in which the storm is travelling. This may require a little practice and a good deal of patience at first when one finds that one has exposed the plate just too soon or too late, or a little too much on one side, to catch the flash. But in this experience is the best master; and the gratification of at least getting one flash squarely on the plate will well repay one for the time and plates wasted, to say nothing of being in all probability drenched to the skin.

Some time will probably elapse before one will be able to secure a picture of a flash at all; but with perseverance and coolness anyone should have a better showing than that of four gentlemen who, to the author's knowledge, expended six dozen plates one night, with lightning playing all around them like fireworks at the Crystal Palace, but in the morning there was not a single trace of lightning on any one of their plates. It is always as well to know the distance the storm is away, which will assist the photographer in judging the direction it is taking, and the speed at which it is travelling. If one second intervenes between the flash and the beginning of the thunder, the nearest part of the shining track is just 1,180 ft. If five seconds intervene, it is 5,900 ft., or a little more than a mile away. As a rough estimate, every five seconds of interval between the lightning and the thunder may be taken to represent a mile of distance.

THE Société Française de Photographie has shifted to fresh quarters at 51, Rue de Clichy, Paris, to which all communications should now be addressed.

PHOTOGRAPHIC Studio Burned.—About ten p.m. on Thursday last the studio of Mr. W. D. Hunter, photographer, of Denny, was discovered to be on fire, and, notwithstanding that the Fire Brigade was early on the ground, the premises and contents were entirely destroyed.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

* * We do not undertake responsibility for the opinions expressed by our correspondents.

ORTHOCHROMATIC RATIOS OF PLATES.

To the Editors.

Gentlemen,—I would like, if I may do so, to offer a few remarks upon Mr. R. S. Potter's letters. His criticism of the method of testing orthochromatic plates used by Mr. Kenneth Mees appears essentially to consist in pointing out that, while in this test the constituents of white light are divided into two groups, and the actual speeds to these found by a refined H. and D. test, he thinks the speeds should be ascertained to lights of equal luminous intensity,* instead of using them in the proportions in which they occur in white light.

If perfect orthochromatic rendering is to be aimed at the criticism is good, but if Mr. Porter knows anything of commercial orthochromatic plates, he must know that this is rather out of the question with almost all of them. Their chief use lies in landscape work in conjunction with a yellow filter of the type Mr. Mees uses in his test; and, therefore, I think that, considering the present qualities of plates upon the market, the tests published are those most likely to be of service to readers of the *BRITISH JOURNAL*.

Mr. Porter's own remarks do not appear to be above criticism. In last week's *JOURNAL* he starts by stating that for a plate that will render any subject correctly, irrespective of its compound colours, the ratio of the blue sensitiveness to the yellow sensitiveness is unity. But he neglects to tell us why he makes this assumption, and also what he means by yellow sensitiveness in this case.

There is, I have reason to believe, a great deal of misunderstanding of this term yellow sensitiveness. If one photographs through a yellow filter, such as Mr. Mees uses in his tests, then the photographic image, in nine cases out of ten, is not produced by the action of yellow, but of green light. For it must be remembered that the yellow light transmitted by the filter is compound, and contains but little pure light that is yellow, being chiefly made up of red light and green light, and of these the ordinary orthochromatic plate is not sensitive to red light.

It must follow from Mr. Porter's "ideally orthochromatic plate," which records all colours correctly according to their luminous intensities, that the yellow sensitiveness in this case is a sensitive-

* I use the term luminous intensity in preference to visual luminosity when speaking of the brightness of lights, because luminous intensity and visual intensity are coming to mean distinct things.

ness to all the components of the compound yellow. But suppose now, that the equality of (compound) yellow sensitiveness and blue sensitiveness were obtained with a plate of the common erythrosin type, it would mean that the blue sensitiveness would have to be about doubled to compensate for the absence of red sensitiveness. So that, although the ratio of blue to yellow sensitiveness would in both these cases be unity, the actions of the plates in photographing red or green colours would be very different.

The whole point is this, that if perfect orthochromatism is to be examined for, the speed tests must be made by red, green, and blue lights of equal luminous intensity, and not by compound colours such as yellow. It, therefore, becomes impossible to accept the preliminary definition laid down.

I would like to point out that, however useful Mr. Mees' tests may be as a guide to camera exposures, there are several purposes for which the knowledge given by an exposure to a spectrum is essential. Among such I may instance the selection of plates and adjustment of filters for three-colour work, the adjustment of certain types of orthochromatic filters and determination of the nature of the colour sensitiveness of plates.

There is only one point of criticism which I should like to advance upon Mr. Kenneth Mees' excellent tests, and that is that he, I believe, makes no allowance for the general absorption of his filters. In all probability the blue filter absorbs more blue light than the yellow filter does of the various coloured lights which it transmits. The point is a small one, as perhaps the most useful figures for outdoor work are the speed tests of the unscreened plate and the plate under the yellow filter.—Yours faithfully,

A. J. BULL.

PORTRAITS IN COLOURS.

To the Editors.

Gentlemen,—Referring to your note in "Ex Cathedra" on portraiture in natural colours, I have thought it exceedingly peculiar that no one in England has up to the present done anything in this direction. I have followed very closely all matters relating to colour work, and cannot myself see any reason why portraiture in natural colours should not be an accomplished fact.

I am at present privately working a process that is entirely practical, and that can be worked in any well-lighted studio; it only requires to be introduced in a high-class studio to a wealthy clientèle to enable it to be carried on successfully.—Yours faithfully,

BERTRAM T. HEWSON.

Elham, Canterbury, August 21, 1905.

THE ACTION OF METOL AND ORTOL ON THE SKIN.

To the Editors.

Gentlemen,—I note in the Answers to Correspondents you advise the use of ortol instead of metol where the latter causes skin troubles. May I point out that ortol has also the same effect on the skin in some cases, as I can speak from personal experience, and also in the case of others; and this may perhaps be explained by the fact that I believe metol is a derivative of ortol, the latter being an antecedent of both metol and hydroquinone.

I am not only interested in this question from the practical point, but also professionally, and shall be very glad to have particulars of any skin troubles set up by the use of chemicals employed in photography, as I think mysterious skin eruptions in photographers are sometimes due to certain chemical substances of which our knowledge is limited.—Yours, etc.,

A. R. F. EVERSHED.

[Our correspondent is not quite correct in stating that metol is

derivation of ortol; metol was introduced as a developer about 1892, ortol not till 1897. The former is the sulphate of monomethyl-*ortho*-amido-phenol; ortol is a mixture of one molecule of hydroquinone and two molecules of sulphate of methyl *ortho*-amido-phenol. We shall be glad to hear if any of our readers have suffered in the manner to our correspondent. We may state that we know of no case in which metol acts as an intense irritant, whilst ortol can be used with impunity.—Eds., B.J.P.]

CALCULATING ENLARGING EXPOSURES.

To the Editors.

Gentlemen,—The excellent article by Mr. Beck on this subject in our issues of August 11 and 18 is full of practical information of a thoroughly sound character.

It will be noted, however, that the necessary calculations have to be made by pen or pencil, six factors being considered. Now, when an actinometer is used for estimating an ordinary negative exposure, very few persons make the required calculation by pen or pencil, but the slide-rule provided with the instrument. If this is found convenient with a simple exposure problem involving only three factors, the convenience of the slide-rule method will be still more in evidence, when at least six factors have to be considered, as in an enlarging problem.

Our object in writing is to point out that the end desired by Mr. Beck—viz., to calculate the size of diaphragm to use to make the enlarging exposure equal to the actinometer exposure—can be attained by the scales both of our Standard meter and of the Bee meter without having to make a pen or pencil calculation at all. In the Standard instrument the six separate scales are provided, and it is only necessary to set actinometer and exposure to equal values (say, 1) plate, enlarging, and subject scales to their values, for the pointer D to indicate the right diaphragm to use, there being no need to consult any table of figures.

It will, perhaps be more generally useful to point out how the same result can be attained with the little Bee meter, especially as it has not previously been given in print.

The scales here provide only for the factors of plate, diaphragm, actinometer, and exposure, and two additional ones (subject value negative, and enlarging factor) have to be provided by consulting the table given in "Exposure Notes" and in our "Manual" as below:

Times focus from lens.	Enlarging diameters.	Thin Neg.	Medium Neg.	Dense Neg.
2	equal size	1	2	4
2½	1½	1½	3	6
3	2	2½	4½	9
3½	2½	3	6	12
4	3	4	8	16
5	4	6½	12½	25
6	5	9	18	36

The first two columns of the above table are alternate methods of expressing the enlarging factor, and only one of them is used. For instance, in Mr. Beck's second example the focus of the lens is 7 in., and distance from stop to easel is 28 in. This is four "times focus from lens," and if opposite the 4 in first column the figure under "dense neg." is noted it will be found to be 16, which means that the necessary exposure would be 16 times that worked out from the usual factors on a meter, or that a diaphragm of 16 times the area of the one indicated by the usual method must be used to make the enlarging exposure and actinometer exposure equal.

Now to explain how the scales of the Bee meter are to be used in conjunction with the above table to indicate diaphragm to use to make actinometer test and enlarging exposure identical:

Having noted the "times focus from lens" and the classification of the negative, note the resulting figure in the above table, which is 16 in the example quoted above. Look out this figure 16 on the plate scale of the meter (that is among the figures to the left, with dashes against them). Set *f*, 8 (as an indicating pointer) to this figure. Then against the plate speed number of the paper to be used will be found the required diaphragm to use—*f*/10 in above example with speed 22.

Mr. Beck's excellent general instructions can be followed. But as regards speed number of paper, it will be found that with so many factors for individual observation, no two users will find the same number correct, and whether taken from Mr. Beck's list or our own speed card, it may have to be very widely altered for each individual.—Yours truly,

WATKINS METER CO.

Hereford, August 18, 1905.

AN ACETYLENE QUERY.

To the Editors.

Gentlemen,—Can you inform me the number required, size of burners (and make), and best arrangement of them, for acetylene gas apparatus for portraiture (only), to be used in umbrella-shaped reflector. I am fully conversant with method of gas production, etc., but for coming winter wish to get shorter exposures than I could manage through last winter. The enclosed photographs required about twenty seconds with 12½-ft. per hour burners. Dallmeyer 2 B lens, slightly stopped down. Perhaps some of our readers could give a few hints. Thanking you in anticipation.—Yours truly,

August 21, 1905.

GEO. E. ORGAN.

[The specimens enclosed are excellently lit examples of studio portraiture, and little or no movement is shown, considering the long exposure necessary. Possibly some of our readers who have employed acetylene as a source of illumination in the studio will be able to give our correspondent some advice.—Eds. B.J.P.]

STUDIO CONSTRUCTION.

To the Editors.

Gentlemen.—In your "Answers to Correspondents" in the issue of the B.J. dated August 18 (*re* studio query of "Member P.P.A."), I would earnestly advise this gentleman not to have the ridge of his studio roof central. If he does, he will find that with a sitter seated at 9 ft. from light side (or 9 to 10 ft.) the blinds will have to be drawn down nearly half-way, thus cutting out half the light.

Another point I would mention is that Robinson's system brings the light nearer to the head of sitter, thus making it more harsh.

As against the ordinary span-roof building, the glass, in a single slant, with a central ridge, would be quite 2 ft. 6 in. nearer sitter's head.

Another point is that with spring blinds and the ridge central, the blinds would be difficult to keep flat, they would be always bellying.

As his studio faces west, I would urge him to have the ridge 12 ft. high and only 2 ft. from light side. He can then seat his sitters 9 to 10 ft. from light side, and use the whole of his light; and, further, he will be free from the sun half the day. As he lowers the blinds his sitters can approach nearer the light for stronger effects. In fact, he would do well to do away with all top light, carrying the side light up to 14 ft. high. He would then have no difficulty with his blinds.

Did your correspondent find any cure for the sun troubles? I have myself tried various supposed remedies, but still, in the height of summer, get the sun in my negatives.—Yours faithfully,

SPAN ROOF.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- S. Hill & Son, 170, Bolton Street, Bury, Lancs. Four Photographs:—Hospital for Incurables, Robinson Kay Home. Interior of Art Gallery, Bury. Entrance Hall, Art Gallery, Bury. Lancashire Fusiliers' War Memorial, Bury.

GLASS FOR STUDIO.—Would you kindly say if "Hartley's rolled 4th plate glass" is good for studio light, i.e.—if it passes more light or as much as ground glass? Above rolled 4th plate is strong, moderate in price, and prevents anyone looking in studio. I do not like ground glass—it diffuses light overmuch.—HELIO.

The rolled glass will do very well, and it is largely used for glazing studios. If you get the whitest kind you will find it does not obstruct much light. We have not, practically, compared the two glasses, but we should think there would not be a great difference between them.

MAKER OF LENS.—Can you inform me the maker's name of a portrait lens lettered as follows:—"Pacsa, 43, Charterhouse Square, E.C., No. 3 portrait"? The lens is so made that when used without a stop the slot can be racked under the outer tube.—SPAN-ROOF.

We cannot say the name of the actual maker of the lens. It is probably a French one supplied by a company that, a good many years ago, had premises in Charterhouse Square.

F. F. HOWARD.—The miniatures are usually covered with thin sheet celluloid, not gelatine. Simple apparatus for the purpose is supplied by Jonathan Fallowfield, Charing Cross Road, London, W.C.

OWNERSHIP OF BLOCKS.—Kindly favour me with your advice upon the following:—A year ago I supplied to a firm a number of small hand-books containing views of their works, etc., etc., and to prepare these had a quantity of half-tone blocks made. They are now writing me demanding these blocks, and stating that unless sent at once proceedings will be taken. As in my quotation no mention of supplying blocks was made, I am not prepared to let them have them. I would like to know whether

they have any claim whatever to these blocks? I contend that they have no more right to blocks than they would have negatives taken for them to supply prints from.—NOEL.

It seems to us that the customer has no more right to the blocks than to the negatives, unless a special charge was made for them, which does not appear to be the case. We must say, however, that we cannot call to mind any case in which the ownership of blocks has been raised in a court of law. You are a member of the Professional Photographers' Association; you should communicate with the secretary; he may be able to answer you more authoritatively than we can.

THREATENED PROCEEDINGS.—My assistant called for an account of the house of a troublesome customer, at a time, which he understood, appointed by that customer; but, not having any answer to repeated knocks, he left a card (similar to enclosed) slipped in a crack in the porch. The customer threatens to take proceedings for exposure. Can this be done?—F. COLEY-SMITH.

This is simply a case of "bluff." The customer has no cause of action if the facts be as stated. If the man does not pay, take proceedings in the County Court.

D. P. A. E.—You do not state what toning bath you used, but we should certainly say that you somehow introduced traces of hypo into it.

E. H. LORD.—Your print was registered by us on January 2, 1903, and was sent us from Blackpool, so that there is no need for any search. We should think your claim is reasonable, but you might demand delivery of negative and a prints. In case of no notice being taken of your letter, you would have to employ a solicitor to fight the case; the "copyright law" will not take any action. If you were to join the Copyright Union, 23, Soho Square, W., or the Professional Photographers' Association, 51, Baker Street, W., they would take up all such cases for you, and in both cases the annual subscription is small.

EXPERIMENTER, GLASGOW.—Your idea, if practicable, would certainly be a boon, but the great difficulty with this process has always been, not want of register, but the difficulty of printing all three colours within a reasonable time and then insuring absolutely equal distribution of the ink over a long pull. As a matter of fact, this difficulty has practically knocked the process out, as it was found possible to obtain not more than about 25 per cent. of the pulls with equal distribution of each and all colours, therefore, although the cost is in the first place proportionately low, the rejection of at least 75 per cent. raised it to a prohibitive limit.

* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Another Poisoning Case by Bichromate of Potash.

Bichromate of potash has of late been getting itself into notoriety as a poison. A few weeks back we mentioned a case in which this salt was used by a suicide to put an end to her existence.

Last week an inquest was held at the East London Coroner's Court on the body of another unfortunate woman who had poisoned herself with the bichromate. It was not stated in the evidence what was the quantity of the salt the woman had probably swallowed; but it was presumably large, as the solution was taken from the stock of her husband, who is a French polisher by trade, and uses the bichromate for darkening wood, for which purpose a tolerably strong solution is generally employed. This is only the second case we can call to mind of bichromate of potash being used by suicides. In the first case, which we commented upon in our issue of July 28th, the doctor, called in, is reported to have said that one-fifth of a grain of the salt was enough to have killed the woman. As we said then, we doubted very much whether this was correct. Those who have much to do with the bichromate and crush it in a mortar must frequently swallow more than one-fifth of a grain in the shape of dust, and they must often inhale much more than that through the nostrils.

It is curious that in two cases out of the three recent fatal ones occurred in connection with the use of the salt in French polishing. In the first one the solution was drunk in mistake for beer.

While upon the subject, we may mention that in pulverising bichromate of potash the finer particles become disseminated through the atmosphere, and when inhaled produce an irritation of the mucous membrane, sometimes causing a violent sneezing. The best way of avoiding this nuisance is to sprinkle just a few drops of water on the crystals before commencing the pulverisation. It has been said that bichromate of potash used to be employed as an adulterant of snuff, to give it greater pungency. Be that as it may, it is a great irritant of the mucous membrane.

* * *

A New Direct Carbon Process.

The carbon process is, undoubtedly, far more extensively employed at the present time than it ever has been since its introduction, now some forty years ago. Its great drawback is, and always has been, the transfer operations. The procedure is certainly troublesome as compared with some modern printing methods; but still the results to be obtained, and the variety of colours available, are not surpassed by any other printing process, and, what is more, the prints made by it are without question the most permanent of all photographs. At the recent Photographic Congress at Darmstadt, reported last week, a demonstra-

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

PRELIMINARY ANNOUNCEMENT.

THE forty-fifth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,612 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1906 will also consist of 25,000 copies.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1906 will be modified to make it more than ever the book of universal photographic reference. As in the past, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1906 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded, and wherever practicable new features of an informative nature will be added.

**** IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1st, so as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

tion was given of a new carbon process that does not involve any transfer, it being a direct printing process. Paper is first coated with plain gelatine, which, we assume, is of a somewhat insoluble nature, inasmuch as a second and thin film containing the pigment is applied. The paper is sensitised in a dilute solution of bichromate of potash. The development of the picture, after printing, is somewhat similar to the development of the Artigue paper, except that in place of the "sawdust soup" a fine spray of water is employed. Of course, with this the operator has great scope for local treatment and the production of varied effects. When finished, that is, after the alum bath, the prints are put into a water varnish, but for what reason we are not aware, as the pictures are said to have a matt surface, and not the rich appearance of ordinary transfer carbon ones. If this new process is capable of yielding results equal to the ordinary carbon process for general every-day work, there should be a great future before it, for there is no question that, if it were not for the transfer operations, carbon would be the most popular printing process of the day.

Photographic Portraits and Testimonials.

At the present time, as readers of "popular" journalism can see, the proprietors of quack medicines and other nostrums utilise photography largely in their advertisements. No doubt they consider that the portraits of beneficiaries from their preparations add materially to the value of the advertisement. Hence we see portraits of chubby children said to have been brought up upon Blank's food; of ladies with a profusion of hair, alleged to have been produced by a certain hair restorer or wash; portraits of persons in robust health, stated to have been brought about by taking some or other of the meat extracts, or perhaps some celebrated pill. There is, we think, little question that this kind of advertisement has weight with a certain section of the public, and in some cases also brings grist to the mill of the photographers who take the portraits. In some cases, we are informed, when a testimonial is sent the sender is asked for a portrait, with the intimation that the sitter's photographer will be paid for taking it, and a dozen platinotype copies presented to the sitter. The photographer often gets orders for enlargements from the negatives, or, sometimes, the negative itself is purchased for a good price by the advertisers. Special prints also are frequently wanted for process blocks. One photographer whom we know was told by the representative of a firm utilising photography in this way that, if he knew any one who would write a testimonial after trying the preparation, the firm would pay him, the photographer, for a dozen platinotype portraits for the writer. We understand this is the usual custom with those who embellish their advertisements with portraits.

* * *

Colour Photography for the Shop Window.

"There is always somebody looking in —'s window," was a remark we heard made of a photographer's establishment in a Midland town the other day, and we were not surprised to find that in addition to a few fine specimens of portrait photography, there were several good photographs of local happenings. An opportunity for turning to advantage the public interest in colour photography offers itself just now, and may well be seized by those who are looking for something to draw attention to their window. A finished and framed three-colour print, produced by the triple-pigment process, is offered by the Rotary Photographic Co. at a moderate figure, as a means of demonstrating to photographers the results obtainable by their stripping-film process of photography in natural colours. Given a central position in the window, and

supplemented by an explanatory ticket stating that it represents a process which is now before the public, such a specimen should make, for the time being, the exhibitor's establishment notable above those of his competitors.

* * *

Autumn Exposures.

With the close of August the summer of 1905 may be said to have terminated. Photographers, especially amateurs and others whose exposures have been mostly made out of doors, cannot have much cause for grumbling at the proportion of sunny days vouchsafed us during the past three months, and although we may yet, before winter sets in, have several periods of bright sunshine and even extremely hot days it will be noticed that the actinic value of the light will now begin to appreciably decrease. This will be observable more particularly before 9 a.m. and after 3 p.m., when the power of the light drops off in a remarkable degree. In the studio, daylight exposures that were possible at 6 p.m. a month ago are now becoming a matter of difficulty, and will soon be entirely impossible. This shortening of the photographer's working day during the autumn months is always a serious consideration with the man who has not an artificial light installation, and who is therefore forced to crowd the whole of his day's sittings into a much shorter time than during the summer, and it behoves the busy professional to look ahead, and bear in mind this daily curtailment of his working light when booking appointments.

* * *

A Film Patent.

A series of French patents taken out by the Verein Glanzstoff-Fabriken Act. Ges. includes the manufacture of a tough and transparent film from cellulose through the agency of the well-known ammoniacal copper solution. It is difficult to think that the process as described will produce a film of colourlessness and transparency sufficient for photographic purposes, but we give it as we find it:—Solutions of cellulose in ammoniacal copper solution are forced through small orifices into solution of sodium or potassium carbonate, and the product, which is thus coagulated, washed and dried under tension. It is immersed for about fifteen minutes in a strong solution of sodium carbonate containing 2 to 6 per cent. of ammonia, by which treatment, it is stated, a material of considerable elasticity, tenacity, and transparency is produced. It is freed from the whole or part of the copper it contains, and finally dried under tension. It is not pointed out in what respect elasticity in a film is a qualification for its use as the base of a photographic emulsion, and we do not anticipate in the process the key to the manufacture of the perfect transparent, flexible, but rigid support.

* * *

A German Professional.

We congratulate our handsome contemporary, the "Photo Era," of Boston, U.S.A., on the prominence given in its August number to the work of Herr Rudolf Dührkoop, professional photographer, of Hamburg. Few representatives of the craft in Germany could produce ten photographs as different in treatment as those reproduced in our contemporary. It has been our pleasure to have seen a good deal of Herr Dührkoop's work during the last few years, and we have marvelled at the great versatility of its producer. He has no formula for lighting, no trick of the studio by which to turn out portraits as by machine. He is not a photographer of men or of women only, but shows a refined strength in the choice of treatment for sitters of varied types. A number of his portraits are made in direct sunshine, and others in the homes of his clients. Herr Dührkoop, with one or two more of his countrymen, such as Perschied, Müller, and Raupp, sets a standard in Ger-

many which the rank and file of the profession in that country do not appear to value sufficiently. Certainly, if we may judge from the work of the average German studio as we have seen it, there does not seem any disposition to emulate the example of these leaders.

Plate Packing.

A word of commendation of British articles of manufacture comes from Port Antonio, Jamaica, where the United States Commercial Agent reports that the photographic plates come chiefly from England. He attributes the satisfaction which users have found in the British manufactures to the greater care in packing as compared with plates from America. The English plates come enclosed in waterproof paper, and are well protected against the light and moisture of the West Indies. American plates are stated to have been unsuitably packed and to have been sold in a condition in which good negatives could not be obtained. When so much criticism is levelled against the allegedly conservative methods of British manufacturers in their dealings abroad, the British photographic factories may compliment themselves on having obtained and kept the business in plates and papers by a keen recognition of technical requirements.

SOME ASPECTS OF PHOTOGRAPHIC COPYRIGHT.

The fact is sometimes dwelt upon by those professing themselves dissatisfied with the law as regards artistic copyright that photographic works are in all respects entitled to the same degree of protection as those of the draughtsman, painter or engraver. And this equality sometimes seems to be regarded as a sort of grievance by those who would have us relegate the photograph to a plane beneath that of the work of the graphic craftsmen, whose methods are wholly that of the trained hand. Whether photography is or is not a mean thing in comparison with the other graphic arts does not, however, in our estimation, bear upon this discussion of copyright law; or perhaps we ought to say that it cannot do so as long as the law grants copyright to the authors of works (drawings, etc., not photographs) which by no stretch of imagination can be brought within the class of works to which the term Art is commonly applied. The amateur and immature painter in water-colour may produce a sketch of some scene of nature or evolve something out of his own inner consciousness, and either may be artistically as bad as you like—under the Act he has the copyright in it. Therefore, until a distinction is drawn between what is art with a capital A and what is merely painting or drawing, good or bad, it is idle to talk of herding together drawings, works of art, paintings and the like as the sheep on the right hand to receive the blessings of copyright protection, and standing photography on the left as the goat to be delivered to the destroyers. We waive for the present occasion any claims which photography may have to be regarded as fine art, and to be capable of originating works which have individuality equal with that of the painter's; our argument is of a lower order, and while in the foregoing we have referred to a point of copyright law which takes away the force from the criticism which disputes photography's claim to copyright on the ground of its alleged artistic sterility, we would now proceed to mention other considerations which are perhaps not recognised as much as they should be in relation to the question of copyright.

An authenticated photograph is a certificate of fact. We say authenticated because of certain practices which we will refer to directly. But for the moment, without qualification, a photograph, as everybody knows, implies the existence of a material object or the occurrence of an actual incident. This character of a photograph, which is not

shared by the work of an artist in whatever medium, imparts a character to it which may in a large proportion of instances give it a very considerable value. In illustration the modern craving is for facts. That demand from the public is supplied in popular journalism of all kinds. If a photograph of a notable event is obtainable it is preferred to the work of an artist, for the reason that the public know enough about photography to understand that it certifies as well as illustrates the incident. Indeed, the public has probably an exaggerated idea of the accuracy of which the photographic record is capable, and of the trust which is to be reposed in it in regard to details. But the main issue is that the photographer must have been on the spot, while the artist in a studio on the Thames Embankment can give his fancy rein in anticipating the fall of Port Arthur or the disaster to Admiral Rojestvensky's fleet. This "certificate" character of the photograph, therefore, confers upon a photograph a value which may be out of all proportion to its technical excellence or to its qualities as a work of art, and the Copyright Act, defining copyright as it does as property, rightly safeguards the interests of the author, quite apart from the legitimacy of the work as Art. In thus granting copyright indiscriminately the Act places no definite value on copyright. The market of artistic wares fixes that, and in the end painter, black-and-white artist, and photographer obtain the reward of their labours as the state of the illustrative world determines. If a photograph is infringed, the Courts fix the penalty, but, in the natural order of things, are governed in their rulings by the custom of the trade. And so it comes about that in the case of a photographer who has the sole copyright in two photographs, one an ordinary view of the Law Courts, and the other one in which the principals of the current divorce scandal are seen leaving the gates, the former is practically valueless, because there are hundreds more like it, but the latter is a more or less valuable property from the fact of the parties represented. The second photograph, moreover, has cost the photographer very likely as much as half a day's preparation and lying in waiting. He has had to put himself in a position to recognise Lord A—, and has wasted an hour or two in getting his exposure. That form of labour represents a certain value in the copyright, and the money spent in creating a photograph by such means can often be assessed with fair approach to accuracy. In some cases this expenditure may amount to large sums. A photographer returns from parts of the world little explored with a series of negatives. His exposures represent capital laid out in the creation of copyrights, and nobody will surely take such an inequitable view as to argue that because there is nothing artistic in the prints that, therefore, they can be copied with impunity, or that they have not a value many times greater than that of the average subject which can be photographed by anybody with very little trouble and expense. Apparently French law grants copyright in photographs only to those photographers who have shown themselves capable of work possessing individuality, but we should be very interested in hearing how a French Court would view the rights in photographs which an explorer may bring home from his travels. If there is any market for such photographs they are at least worth what they cost, and we would insist again that their value is enhanced for modern illustration purposes by the fact that they are photographs, and from their very method of production obtain a value peculiarly their own.

In reverting to this latter point we may, in conclusion, briefly refer to a matter hinted at in a previous paragraph, and that is the existence of "faked" or bogus photographs. How can a photograph be any guarantee whatever of facts, when reproductions of photographs alleged to be taken of actual events have been shown to be frauds, or when actual

photographs have been shown to have been doctored to an extent unsuspected by the public? That query is partly legitimate, but it disregards the fact that the bogus or "faked" photograph is almost invariably the production of those who afterwards give it to the world through the printed page. It is easy enough to doctor a photograph of some event without the fraud being discoverable when the picture takes the form of an indirect photograph from a half-tone block. The production of a direct photographic print which does not bear on itself the marks of faking is a much

more difficult matter, and, as the business in photography is done through originals, the publication of the bogus photograph does not directly affect the question, except that such reprehensible practices do the most serious injury to the profession of photography for illustrative purposes in general by destroying public confidence in photography. The total effect, however, of the "faked" print is no great enough, in our judgment, to diminish appreciably the growing value of photographs as pieces of pictorial evidence.

VIGNETTES AND VIGNETTING.

II.

The Head and Shoulders.

"Place aux Dames."

I ONCE heard a man who knew no French translate "Place aux Dames" as "Please the Ladies." I treasured up the saying, and if ever a saying, an accidental and even stupid one, came in handy, it does so now. "Please the ladies!" The photographer has to do this or his occupation is gone, for although I will scarcely venture to assert that when a man enters the studio of painter or photographer there is necessarily a lady in the case, it does so happen in ninety-nine hundred and ninety-nine cases out of a hundred, as a South Kensington professor was wont to remark until pulled up by the smile of his students, that some lady is interested, may even be the arbiter of the photographer's success or otherwise. Of all ladies, the most difficult to please is the matron; I dare not say why, although I could. "The young person" is an awkward sitter, but easy to please; how her awkwardness is best got over is for the young and good-looking operator in the studio to say. Somehow or another he makes the printer's task an easy one. Mrs. Merdle, Dear Little Buttercup, and Tante Sannie (*vide* Olive Schreiner's "South African Farm") are a task which the printer has to deal with, and often suffer from.

Not a small matter either is the undoubted fact that one of the most important, if not the most important factor that the ladies' photographer has to deal with is the dress or costume, and the task is often further complicated by the hat or bonnet or something that goes by the name of "toque."

The Vignettes for Portraits of Women.

The fact that a lady likes her dress to be seen, even in a vignette bust, may explain to some extent why the vignette has to be carried down lower in the case of the lady than the gentleman. It must be done; the rule has hardly an exception, but the exception is more often made the rule, owing to the use of the mechanical vignette. The mechanical vignette may pass muster for most males. Where ladies are concerned, its use is an atrocity to be shunned, except in such rare cases where the lady has no waist. I almost despair of making my meaning manifest. The matron is, photographically, the most difficult subject the photographer has to tackle. Apart from her age, her sex, and her position, you have got to bear in mind that photography must be truth or nothing, even though truth disguised and only half a truth. In the case of the matron, it is more a matter for the studio to deal with than the printing room. In any doubtful, even only slightly doubtful, cases the man who has taken the cap off should say a word on the special subject to the printer; if he does not there is trouble ahead. The artistic sense of the operator, if he has any—and there is scarcely an "if" in the case should he retain his job longer than the very first week of his engagement—will determine the style in which his sitter appears to most advantage; and, if he be a man who values his own position, reputation, and situation, he will give directions and cautions to the printer in doubtful cases. Certain broad rules may, however, be laid down for the printer's behoof.

Maxims for Vignette Printers.

The shaded background must appear well round the head must invariably appear above the head in proportion to its extension at the side of the face. You can scarcely go wrong for the lady sitter always does have hair: she takes good care of that—but how she does it is no particular business of yours. The shoulder and the junction of the arm she will also take care of; in fact, the arrangement of the dress in a case of head and shoulders only may safely be left to her. A somewhat ungainly style of shoulder-joint to the dress is sometimes in fashion, and is dignified with the name of "epaulette" (save the mark!). This must certainly appear, if you wish to represent yourself as a "fashionable" photographer, but it is the special business of the vignetter to tone this down, to vignette especially the portion as it were and make it less intrusive. Here the brush method of vignetting is invaluable. A few fine strokes close together rather than only one or two big ones will allow all of fashion's minute detail to appear without giving them undue prominence by heavy printing. Of course, it is the operator's duty to see that there is no ungainly pucker; and, in this, as well as in the manipulation of drapery generally, he will do well to call in the assistance of the presiding goddess of the reception room. This little detail, however, is a matter with which the printer has nothing to do, but it is as well to mention it lest the printer be blamed for what has been the result of careless or superficial scrutiny of the sitter on the part of the "operator."

Full face and Profile.

In a portrait where the lady's figure is square on, or nearly square on, to the lens, the buxom charms of the lady entail no trouble on the printer's part, but it cannot too strongly be insisted that the vignetting mask suitable for the mere man is unsuitable for his better. The tapering of the body towards the waist must be indicated but not defined, and, of course, the pattern, if there is any pattern, of the dress material shown. If this last point is attended to, the necklet, the brooch or locket, and the chain will all find due prominence in what the lady will choose to consider a successful portrait.

The treatment of the feminine side view is the most awkward part that the vignetter has to undertake. The lady with a full bosom, the one who is really vulgarly fat (if she only knew it), is exactly the lady most apt to pride herself on the possession of a fine and commanding figure, and to insist strongly on a form of portraiture to which her figure is least suited. You cannot get out of it, and must make the best of a bad job. Do not vignette too close up to the figure, nor let the vignetting be too graduated. Leave sufficient background to tone down the figure projected against it. Nor do not cut off the background too high up or you may only make bad worse. Should the indication of the figure stop short at the point where it turns in towards the waist, the check at a critical moment is only too suggestive of "to be continued in our next."

Portraits of Men.

The full-view bust portrait of a gentleman is the favoured style and the easiest to vignette. Perhaps this is the chief reason why it is usually done worst. The mechanical vignette is the rule, and is clapped on the frame regardless of special fitness. The portrait is fully printed nearly down to a line joining the armpits, and then graduated off. All very well in its way, provided that the coat fits well, is neatly joined at the shoulder, showing no imitation of the lady's epaulette or ungainly droop between the neck and the shoulder—this last being an obstacle for the operator, not the printer, to overcome. The chief trouble in the use of a mechanical, or general, vignetting mask is that it makes too little allowance for hair thinning or a cranium that has reached the stage of baldness. Nothing looks worse than a bald head against a lot of dark background. Bring the strokes of your paint brush on the vignetting mask well down to the outline of the head. The head will make itself prominent enough without your letting the hairless dome stand out like a whitewashed Dutch tomb on a lonely farm. Just an opposite thing must be done if the sitter has a luxuriant head of curly hair. To please him and all concerned in its reception you cannot make a really good head of hair stand out too prominently.

Perspective and the Vignette.

In all cases where the figure is not taken square on to the camera, the use of the mechanical style of vignetting mask cannot be too strongly deprecated. The comparative sizes of the two arms and shoulders—in plain words, the perspective—is already too prominent. The number of old-fashioned lenses built for rapidity that are still in use is large, and the photographer who can afford and has a long studio, where he is

not cramped for room and can use a lens of longish focus, is to be congratulated. However exaggerated the perspective may appear any endeavour in vignetting to disguise it will only make matters worse. The vignette must have the same perspective as the portrait; there is nothing else to be done. For my own part I have a decided liking for a pose in which the shoulders are at an angle with the camera and the face is turned nearly full towards the lens. The very fact that the vignetting requires more attention is nothing to its disadvantage, but the contrary, if it can be managed without exaggerated perspective. But a first necessity for its skilful adoption is that someone with artistic ideas keeps a sharp eye on the printing room. Where the printing is left to the prosaic conceptions of some irresponsible boy or girl, not only the printing room but every department of the business may be as mechanical, as wooden, as possible.

Profile Vignettes.

Vignetting a profile is a comparatively simple matter, far more so than the taking of what the public usually terms "side face." From up high in the back to down low in the breast or chest is the general rule for vignetting a profile. Should the sitter be soldier, sailor, or athlete, or a lady well set up in the back, the vignette may be brought down well below the shoulders and almost level with the front. The straightness of the back must indicate the starting point of back to front view. Alas! Most of us poor humans get so round-shouldered in the course of time that should our facial outlines be good enough for profile representation, the only safe plan to adopt is that of the statuette, which may be described in the words of the directions most of us gave to the barber ere the close-clippers came into vogue—"Short behind and long in front, please!"

C. RAY WOODS.

SOME NOTES ON THE USE OF THE TOURNIQUET.

THE tourniquet is a turntable which can be rotated horizontally about a fixed pivot. On the turntable is an adjustable sliding carrier for supporting a lens, so arranged that the pivot of the turntable is always exactly under some point on the principal axis of the lens. Any point on the principal axis can be brought over the pivot by sliding the lens and its carrier to and fro upon the turntable, and the effect of rotating the lens about certain points on its principal axis can therefore be readily tested. Various effects being produced by bringing either the nodes or the centres of the pupils over the pivot, the positions of these points can be determined by tentative experiment.

To Find the Nodes.

With the ordinary method of using the tourniquet a distant point is focussed on a screen, and the position of the lens upon the turn is shifted tentatively until the image shows no movement when the turntable is rotated. The vertical axis of rotation then passes through one of the nodes of the lens and the position of that node can be recorded, either by marking the lens mount, or by noting the distance of the node from some fixed datum. This method is often somewhat troublesome. The movement of the lens to and fro upon the turntable necessitates frequent refocussing, and in daylight the apparatus cannot be conveniently used unless fitted with a camera body to protect the screen from extraneous light, while with artificial light it is difficult to secure a satisfactory theoretically "distant" test object without the aid of further complications in the way of apparatus. The following method is in many respects more convenient. It obviates the necessity of preserving focus; is applicable in the brightest daylight without the use of any

form of camera body; and is very readily and quickly carried out.

Fix the lens on the carrier of the tourniquet and direct it to a distant object, such as a church spire. A spire seen against the sky is about the best object that can be selected. About eight to ten inches behind the approximate position of the principal focus of the lens set up a vertical screen with a pinhole, arranging matters so that the pinhole is as nearly as possible on the principal axis of the lens. On looking through the pinhole a very clear and bright inverted image of the spire will be seen, provided the pinhole is at the distance of distinct vision from the principal focus of the lens, a little adjustment may be necessary to secure a perfectly clear image. Arrange the whole apparatus so that spire, pinhole, and lens are truly in alignment, and tilt it, if necessary, to bring the top of the spire in the centre of the lens aperture. Next, arrange a fine needle vertically between pinhole and lens at about the position of the principal focus, and adjust the needle until its point appears to just meet the apex of the steeple as seen through the pinhole. This completes the arrangement of the apparatus.

Rotate the tourniquet through an angle of about five degrees, and note if the image of the spire and the needle point still appear to meet. If they are separated move the sliding carrier in the direction that will bring the spire back to the needle point, then swing the turntable slowly from side to side. The spire should now remain over the needle point, and it should retain that fixed position while the tourniquet is rotated in both directions through a certain limited angle. If this is the case the node is exactly over the fixed centre of rotation, and

its position can be recorded. The second node is found by an exactly similar process carried out with the tourniquet turned through an angle of 180 degrees, so that the direction of the lens is reversed.

It may be found with a poorly corrected lens that it can only be rotated through a very small angle without producing any apparent movement of the image. There is a limit to the angle in all cases, and even with a high quality lens the spire may move very rapidly away from the needle when the limit is reached, though that limit will probably be a wide one. With certain lenses of complex or nonsymmetrical form it will also often be noticed that the movement of the spire is very irregular and hesitating. It sometimes momentarily reverses its movement at one particular angle, and then recontinues its original course.

If the lens has a flat field the image of the spire should lengthen considerably as the lens is rotated, owing to the fact that the focal length of the lens is greater for oblique than for direct light. If this effect is not observed, curvature of the field almost certainly exists. If the image becomes distorted laterally during the rotation of the lens it is equally certain that the lens is not well corrected for distortion. With an approximately level apparatus the image of the spire should be perfectly vertical at all angles with a lens free from distortion.

Measuring the Focal Length.

Having found the node of emission, adjust the tourniquet so that the principal axis of the lens intersects the pinhole as nearly as possible, then observe the needle and image of the spire through a second pinhole situated at one side of the hole previously used, and about quarter inch from it. If the needle and spire do not coincide move the needle to or from the lens on the line of the principal axis until coincidence is secured. When the needle and spire coincide through either pinhole the needle is situated at the principal focus of the lens, and the distance from the needle to the node of emission is the focal length. This is a very quick and easy method, and it is also a very accurate one, provided the lens is free from any serious amount of spherical aberration.

Another method available with one pinhole is to remove the needle and substitute for it a piece of ground glass. If the glass is carefully adjusted until a sharp image of the spire is observed upon it when looking through the pinhole, the focal length can be measured from the node to the ground glass. So long as observation is made through the pinhole the image can be observed fairly well without screening the glass in any way, but the method is not quite so satisfactory as the former one.

A third method is to remove the needle, substitute a piece of white card for the pinhole screen, and move the card up to the lens until a sharp image of the sun is secured. This is simple enough if a view of the sun can be obtained, but neither this nor the preceding method is preferable to the first one, unless the lens shows spherical aberration, and in that case the following method has advantages.

If the position of the node of the lens is recorded by its distance from the back of the fixed flange on the lens mount, then the distance from the node to the focussing screen of the camera can always be easily determined by removing the lens, measuring from the screen to the face of the loose flange on the camera front, with the aid of a rule inserted through the flange aperture, and adding that dimension to the known distance of the node from the fixed flange. Hence, if the node has been determined and recorded, we need only fix the lens in the camera, focus on a distant object, and then measure the focal length. The back of the fixed flange is always the best datum for nodal and other constant measurements, for it is always in close contact with the face of the loose flange, and the sum

of measurements from screen to flange and flange to node can always be easily determined. This method of measuring exact focal distances is especially useful when it is desired to adjust the camera for copying to an exact scale.

To Find the Pupils.

Every lens system has two "pupils," or true "effective apertures," and one at least of these pupils is always a virtual image of the diaphragm, formed either by the complete lens system, or by one of its component combinations. In the case of a single "view" lens the diaphragm aperture is one pupil, and it is called the "entrance pupil" or the "exit pupil," according as it is turned either towards the object or towards the image. The other pupil is a virtual image of the diaphragm aperture formed by the lens, and is the apparent aperture seen when looking at the diaphragm through the lens. This virtual pupil is the exit pupil when the stop itself is the entrance pupil, and vice versa.

In a doublet made up of two positive combinations with an intermediate stop both pupils are virtual. The entrance pupil is the virtual image of the diaphragm formed by the front lens, while the exit pupil is a virtual image formed by the back lens, and each pupil can be observed by looking through the lens responsible for its formation. In a well corrected lens a virtual pupil should be a well defined image of the diaphragm aperture, and if observed from a fixed viewing point it should retain the same position, and show no lateral movement (other than a slight contraction from a circular to an elliptical form) during the horizontal rotation of the lens through a small angle about the centre point of the pupil. The position of a virtual pupil can therefore be determined on a tourniquet by a method similar to that adopted for determining the position of a node.

Set up the apparatus as described for determining the nodes, but direct the lens to some parts of the sky so that no terrestrial objects come in the field of view. Stop the lens down to its smallest aperture, and arrange the needle so that it bisects the apparent aperture. Turn the tourniquet through a small angle and note if the needle still bisects the aperture. If not, slide the lens on the turntable until the aperture is once more bisected by the needle, then rotate the lens to test the fixity of the apparent position of the aperture. If no movement is observed the vertical axis of rotation passes through the centre of the pupil, the position of which can be recorded. This will be the exit pupil if the front lens of the objective is directed to the object, and the entrance pupil if the objective is reversed. With the very small aperture the pupil should retain its fixed position during a fairly wide angle of rotation, if it does not the lens is very likely to give distortion.

The test is very easily carried out with a small aperture, but not so readily with a large one. Several apertures should, however, be tested to see if the position of the pupil centre is the same for all. It should be with a well corrected lens, but big differences are likely to be found with poor lenses, which seem to generally possess curved (concave) pupils instead of plane ones.

To Test the Constancy of the Aperture.

When the pupil has been determined, the apparatus should again be directed to the spire, and the lens be once more rotated on the centre of the turntable. If the apparent aperture and the image of the spire both remain stationary the lens is one of "constant aperture," but if the one moves while the other is fixed the lens is of "inconstant aperture," which means that the actual diameter of the effective aperture varies when the distance of the object in focus is altered, and, as a consequence, that exposure, depth, and perspective are not governed by the ordinary rules when the object is very near. When this is the case (and it always is so with a single view or landscape lens),

the distance between the entrance pupil and the node of admission should be carefully measured and recorded, as it forms a constant that is useful to determine by calculation the precise behaviour of the lens on near objects. The fact that a lens is of inconstant aperture is also indicated when the effective aperture of the lens is found to vary according to the side of the lens that it is measured upon. This is also an easy test, as aperture is very readily measured without the aid of any special apparatus, but this test does not give the aperture constant, and the information it affords has only a negative value.

The tourniquet test reveals the inconstancy of the aperture, and also gives a measure of the degree of inconstancy, therefore it is far more useful. From the nature of the test it is apparent that when the aperture is constant the entrance pupil and node of admission coincide, as do also the exit pupil and node of emission. Hence the test for constancy can be made in the first instance when finding the nodes. If there is no obvious movement of the aperture it is unnecessary to make a separate test for the positions of the pupils.

C. WELBORNE PIPER.

THE WEEK IN HISTORY.

The First Sulphocyanide Toning Bath.

PERHAPS it is not generally known that toning with gold and sulphocyanide grew out of the use of sulphocyanide as a fixing salt. At any rate, it is a fact that M. Meynier, who introduced the former twenty-two years ago to-day, had communicated to the French Photographic Society, some six months previously, a note on the employment of ammonium sulphocyanide for fixation in place of the highly poisonous potassium cyanide. I conclude from this that M. Meynier was led to discover the functions of sulphocyanide in a gold-toning bath, although he himself gives no hint of this in communicating his formula to "Photographische Archiv" for September, 1863:—"I have compounded a toning bath with ammonium sulphocyanide for positive paper prints which gives a rose-violet tone. I add a solution of one gramme chloride of gold to one of twelve grammes ammonium sulphocyanide in one litre of water. The yellow colour of the bath after mixing gradually disappears. As soon as the solution is colourless it can be used in the same way that the usual toning baths are employed."

Dry Plates of 1856.

I suppose many even of my younger readers have used a dry collodion plate put on the market several years ago as the "Hill-Norris." Possibly many of them were not aware of the time to which the process of their manufacture dates back. It was exactly forty-nine years ago to-day—on September 1, 1856—that Dr. Hill Norris applied for a patent for rendering collodion films capable of being used in a dry condition. Dr. Norris's process was based on preserving the porosity of the collodion film, and in this respect was an advance on the work of Muirhead, Gaudin, and the others whose leading idea was to preserve the film in a moist condition. Describing his process, Dr. Norris wrote:—"I introduce into the pores of the collodion film, while still wet from the nitrate of silver solution (or after washing) certain substances soluble in, or penetrable by, watery solutions, which substances, occupying the pores of the collodion film, prevent its condensation on drying, and retain it in a sensitive and pervious state, and by this means I am enabled to produce beautiful pictures, either negative or positive, on perfectly dry and hard collodion films, which films are capable of retaining their sensitiveness for an unlimited period. . . . The substances I employ to satur-

ate the collodion films are very numerous, but the process may be described as follows:—Having produced in the film the sensitive iodide of silver by any of the ordinary known means, I immerse the film for varying periods in a solution of gum arabic, or of dextrine, starch, gelatine albumen, gum tragacanth, vegetable mucilages, caseine, gluten, or other such little substances capable of fulfilling the above-named conditions; the films are then dried, and are ready for exposure to light, or may be kept for any convenient length of time and used as desired." Probably the dry plates which came upon the market between 1856 and 1866 were produced by the process as above described in Specification No. 2,029, 1856, but in later years Dr. Norris, from his factory at Stechford, Birmingham, issued very rapid dry collodion plates, as rapid as a first gelatine plate of ten years ago, and owing their speed to silver bromide. But at what stage of his lengthy researches Dr. Norris lighted upon the sensitive properties of silver bromide I cannot say.

Sidelights on Daguerre's "Researches."

One gets some interesting glimpses of the way in which the Parisian scene-painter was making random shots at the secret of fixing the camera image in one or two letters from Nicéphore Niepce to his son Isidore. Writing on September 2nd, 1827, the father says:—"M. Daguerre has been successful in fixing some of the colour rays of the spectrum. He has already succeeded in combining three, and he is working to unite the remaining four. But the difficulties which he encounters increase in proportion to the modifications which one substance must undergo in order to retain many colours at the same time." We hear no more of Daguerre's adventures in colour photography, but this same letter gives an illuminating description of the process which at that time appeared to suggest itself to the scene-painter as containing the elements of success. Here is what M. Niepce says:—"The chemical compound used by M. Daguerre is a very fine powder which does not adhere to surfaces to which it is applied. This powder on the least exposure to light becomes so luminous as in some measure to illuminate the interior of the camera. Its behaviour seems to resemble, so far as I can recollect, that of sulphide of baryta, or Bolognese stone, which likewise retains certain luminous rays."

HISTORICUS.

A MATTER of Minutes.—Australian photographers have shown that when the opportunity offers, or the occasion demands, they are quite equal to any emergency required of them, and the "Australian Photographic Journal" has reported several instances of very rapid photographic performances. Perhaps the last incident of particular note occurred during the visit to Australia of the then Duke of York—now Prince of Wales—when large batches of photographs taken of the various functions, between the hours of two and four o'clock in the afternoon were got ready and dispatched by the

five o'clock mail the same afternoon. It is, however, worthy of mention that the other day, on the occasion of an installation ceremony at a local masonic lodge, Messrs. H. L. Orr and Co., of Sydney, took a flashlight photograph of the proceeding, and, in a corner of the room, developed the plate, made a bromide contact print, which was properly mounted and afterwards handed around for inspection (and orders) within fifteen minutes. Needless to say that in "striking the iron while it was hot," a very large proportion of those present placed orders with Messrs. Orr and Co. for copies.

TWO-COLOUR PRINTS AND TONALITY.

THE following article, by Bernard C. Roloff, which appears in our New York contemporary, *The Photographer*, may be read by those who are interested in its nominated theme, and by others to whom the *modus operandi* is of importance for quite different purposes:—

The writer, when making exposures of outdoor views, has always made it a habit to secure two negatives of the same view, exposing one for the sky, and the other for the foreground. While it is admitted that by increasing the exposure to a sufficient extent it is possible to so develop the plate that the sky will not become too dense before the foreground has reached proper density; yet such negatives in the writer's opinion, have a tendency to flatness and lack that brilliancy so necessary to perfect negative. Prints from such a negative may be made on contrasty paper to secure the needed brilliancy, but through this the sky again loses its tonality.

It would seem reasonable to suppose that if two negatives are made of the same view as stated, from exactly the same position, one for the sky (a short exposure), and another for a landscape, or foreground (normal exposure), they may be developed separately to secure the desired effect in each, and later in printing, the ordinary methods of printing-in a sky may be resorted to with more telling effect than if the sky is printed-in from a stock sky or cloud negative.

Now, while the ordinary methods of printing-in skies (and there are plenty of them) will serve the purpose in connection with the above outlined plan, the writer calls attention to his method of printing-in skies in connection with the above plan as being considerably different and somewhat more effective than most of the others that have come within his knowledge.

The method presupposes a working knowledge of carbon printing, and if by chance any who read this are disposed to discontinue because they have no knowledge of the process, then let them immediately secure a dozen carbon papers (assorted) and plunge boldly in, taking the precaution, however, to ignore in the beginning all the minor details of the directions given by the manufacturers, except only the most important and necessary steps, which are few and exceedingly simple.

The Method of Sky-Printing.

First, in developing the two negatives secured as above directed, endeavour to secure a strong, nicely graded sky, in the negative exposed for the sky, ignoring the landscape entirely and taking the precaution not to develop too far. The landscape negative, on the contrary, should be developed far enough to produce a somewhat dense sky; if it is possible to do this without sacrificing the landscape, the latter, however, being developed carefully to secure the desired effect, even if at the expense of the sky.

When the negatives are finished and dried the sky negative should be placed in a printing frame provided with a shade fastened at one end and bent up. This should be so adjusted that there will be no chance for the thin landscape portion of the negative to print, and so that the sky will be printed strong at the top, and gradually weaker towards the horizon.

Exposing a Test Piece.

A trial with a piece of printing-out paper will show if the shade is adjusted correctly, and this will also give the printing time required, as the carbon should be printed until all the necessary details show in the trial print. Of course, if printing-out paper is used, the printing should be done in as strong light as it is possible to secure, except in direct sunlight. If the sky-print is to be made on some developing paper, such as Rotox (used by the writer) or Velox, the printing should be performed in very much diffused daylight, instead of, as is usually done with the papers, in strong artificial light, the object being

to prevent the shade throwing a shadow over the sky portion of the negative. Additional diffusion is secured by covering the front of the frame with a sheet of tissue paper before tacking on the shade, and small pieces of cotton may be placed between the tissue paper and the glass side of the negative to roughly cover the landscape portion of the latter.

Making the Carbon Print

Insert a piece of sensitized carbon tissue of the colour that the picture is to be in (green for landscapes with an abundance of foliage to preserve the natural effect) in another printing frame with the landscape negative and print the required length of time, afterwards soaking, placing in contact with the temporary support, developing and drying. The sky print upon the printing-out, or developing paper, is now toned and fixed in one case, or developed and fixed in the other, washed and placed in a bath of equal parts of saturated solutions of ferricyanide of potassium and ammonio citrate of iron, to which add two ounces of water to every two ounces of the saturated combined solutions and a few minims of hydrochloric or similar acid. This will tone the sky print to blue, and the intensity of the tint is determined by the depth of printing and the strength of the above-named solution. Wash to eliminate the yellow in the high lights and place in a solution of formaline $\frac{1}{2}$ ounce to 8 ounces of water to harden for 15 minutes, after which rinse and dry.

Now transfer the carbon print to the sky print in the usual manner for double transfer, treating the sky print similarly to double transfer paper, dry and strip. This process will give a print in two colours by the combination of the carbon with some other printing process.

Two-Colour by Carbon Throughout.

If it is desired to utilize the carbon process throughout in this method it is only necessary to make the sky print in carbon of the desired colour (blue, if desired for a two-colour print, or a print the same colour as the landscape is intended to be printed in), squeegee into contact with a piece of ordinary single transfer paper, and develop in the usual manner, and after developing harden in the formaline bath previously given. The resulting print should be a well-graded sky, shading down near the horizon to almost white. If there are trees, etc., projecting into the sky a few touches with a camel's-hair brush during development will cause them to merge gradually into the sky. The landscape negative may now be printed to a sheet of carbon tissue of the proper colour as before described, the sky portion being dense enough to prevent much pigment from adhering thereto. When about to develop, immerse the last printed sheet, viz., the landscape, in cold water with the previously developed and dried sky print and if the precaution has been taken to previously mark the sky portion of the landscape print so that it will not be upside down on the transfer, it is only necessary to bring the tissue and sky print together under water, squeegee as usual, and develop later in the ordinary manner.

Again, some objection may be made to the use of two negatives in producing the sky effect, but this may be obviated by placing an ordinary landscape negative in the printing frame under tissue paper and the shade referred to adjusted so that the sky will print somewhat longer than the foreground, removing the shade to allow the light to strike the foreground for a portion of the exposure. This is an old way of carrying this into effect, but in order to secure the two-colour effect it is necessary to print each separately, either from separate negatives or from one negative as desired; but it is surely no great hardship to make two negatives of the desired view instead of one, as many of us will often make three and four to make certain of a good thing.

Other Suggested Methods.

Place the desired negative in a printing frame prepared as shown in the sketch and as previously described. Insert a piece of ordinary blue-print paper (rather heavy weight) and print the sky to the required depth, *i.e.*, overprint slightly, and finish the print by washing in water and drying. If the plan of two negatives is followed, proceed in the same manner. With a tuft of cotton dipped in an oxalic acid solution or similar bleaching agent (carbonate soda), carefully take out trees or other objects projecting over into the sky, rinsing well after this operation to remove the yellow stain. To prepare this print for single transfer, prepare a solution of

gelatine 1 ounce in 20 ounces of water. Do not make up too much of this as it will not keep, $\frac{1}{4}$ ounce in 10 ounces of water being probably sufficient for one batch, unless it is desired to coat a large quantity of paper. Float the print on this solution or coat it with a soft brush, taking care to secure an even coat. When the gelatine is set it may be immersed in a solution of chrome alum, which will render it insoluble.

Use this paper in the same manner as described for the sky print in carbon, making a carbon print from the negative in the desired colour, and transferring to the blue print, having previously marked the sky portion of the printed carbon tissue to indicate where the sky should come.

MAGNALIUM AND OTHER LIGHT ALLOYS.

EDITORIAL NOTE.

[At a time when no means are left untried to reduce the weight of photographic apparatus to the minimum, the following paper, communicated to the Yorkshire Section of the Society of Chemical Industry, on practical trials with commercial light alloys deserves a place in our pages, even though the particular circle interested is a small one. For the report we desire to acknowledge the "Journal of the S.C.I."]

THE magnesium-aluminium alloy, known as magnalium, is interesting from its lightness, and further that small amounts of heavier metals, such as nickel or copper, may be added to it without raising its density above that of the fundamental metal, whilst at the same time considerably altering its mechanical properties.

Commercial Magnalium Metals.

At the present time, three magnalium alloys are in regular use, denoted by the letters X, Y, and Z. The first of these is for forging or for castings in which strength is a primary consideration. Forging is done at about 330 deg. C., special care being taken to avoid oxidation. The second, Y, is ordinarily used for casting. To secure good results, oxidation must be carefully guarded against, the melted metal must not be agitated or over-heated, and after pouring the casting should be cooled as quickly as possible. The melting point is slightly above that of aluminium. The castings when properly made are clean and sharp. The third alloy, Z, is used for rolling and drawing. Rolling is done between 300 degrees and 350 degrees C. Frequent annealing is necessary unless very hard sheet is required. Apart from the method pursued in rolling, it is stated that soft sheet can be made springy by heating to about 390 degrees C. and slow cooling. Rapid quenching makes it soft. Similar considerations apply to drawing into rod, wire or tube. Frosting is done, as with aluminium itself, by alkaline liquors.

Magnalium v. Aluminium.

It will be noticed that, except for its greater tendency to oxidation when hot, the treatment of magnalium by the foregoing processes is very similar to that required for aluminium. Magnalium has, however, two advantages at least over pure aluminium. Its tensile strength is decidedly higher. This is said to range from 8½ to 10 tons in the case of ordinary castings (Y), up to 23 tons for Z when rolled hard. The most conspicuous advantage is in its behaviour with cutting tools. As is painfully familiar to all who have had to use aluminium, such operations as filing, turning, drilling, and screwing are far from satisfactory with the pure metal. It drags and tears and clogs the cutting edges. Very small cuts have to be taken at high speed, with good lubrication. The case is very different with magnalium. It works cleanly in the lathe. When turned at a surface speed of 100 feet per minute, without any lubri-

cant, long spiral shavings come off and the surface left is free from any signs of dragging or tearing. It is also free from tool-marks, a circumstance which suggests that the softness of the metal makes it flow on contact with the cutting edge. This idea is supported by the curious way in which the metal builds up on to the tool-edge when being turned or drilled without a lubricant. I find that a cutting edge, whose angle is about 65 degrees, such as would do for steel, serves very well for magnalium. A less acute angle, such as is used for brass, is not so satisfactory. When turned in the manner here described, a silvery-white surface is produced on which any polishing operations seem superfluous.

In order to see if the presence of magnesium would render aluminium susceptible to corrosion, I made a comparative test by exposing sheets of magnalium to the laboratory atmosphere for three weeks, side by side with sheets of aluminium, zinc, copper, and brass, all the surfaces being in a precisely similar condition. The magnalium showed no special signs of corrosion, and the laboratory atmosphere had decidedly more effect on the zinc, copper and brass.

Analysis of the Alloys.

As to chemical composition, careful qualitative analyses have been made of drillings from ingots of X and Y alloys and of a piece of soft sheet which is presumably Z. Complete quantitative analyses have also been carried out, but in the case of Y, which was done before the special difficulties of the analysis were fully realised, no great reliance can be placed on the results, which are therefore omitted. The chief trouble was caused by the relatively enormous proportion of aluminium, which appears in each alloy to exceed 94 per cent. In the qualitative analyses, the bulky character of the aluminium hydroxide prevented large amounts being taken and so rendered the detection of minor constituents difficult. Moreover, it was found that in spite of re-precipitation, the aluminium hydroxide carried down large quantities of other metals. For instance, after a second precipitation with ammonia in presence of much ammonium chloride, the nickel (in alloy X) was still present in apparently larger quantity in the aluminium hydroxide than in the united filtrates. It was noticed that on boiling the liquid containing the precipitated hydroxide as usual to expel excess of ammonia, a marked darkening occurred. In consequence of these facts, in all the qualitative work, and also in the quantitative analysis of X, the re-precipitated hydroxide was digested with pure sodium hydroxide solution in a platinum basin. Nearly all the aluminium was thereby dissolved and, after diluting and filtering, the residual precipitate, brownish-grey in colour, was dissolved in acid and then analysed for all metals beyond the "hydrogen sulphide" group in the usual course.

In order to avoid this lengthy procedure, Mr. J. B. Murray suggested the preliminary treatment of the alloy with sodium hydroxide

solution in order to remove the greater part of the aluminium before commencing the ordinary analytical separation. He applied this method to the complete analysis of the sample of soft sheet, presumably Z, and found it very satisfactory. The alkaline solution of sodium aluminate was found to contain most of the tin, which was, however, easily precipitated by sulphuretted hydrogen after acidifying. The results of the analyses may be stated briefly as follows:—

Alloy X contains copper (1.7), magnesium (1.60), nickel (1.16), and antimony and iron in smaller quantities.

Alloy Y contains copper, magnesium, tin, lead, a small amount of iron, and a doubtful trace of antimony. As far as I can judge, Y is intermediate in composition between X and Z, except as regards nickel. Alloy Z (soft sheet) contains tin (3.15), copper (0.21), magnesium (1.58), lead (0.72), and the usual amount of iron, about one-third of 1 per cent.

Traces of titanium were found, presumably derived from the bauxite. Indications of other rare metals were obtained, but the difficulties in the way of taking large quantities of the samples for analysis prevented any confirmatory work. Alloy X dissolved in *aqua regia* left an insoluble residue amounting to 0.38 per cent.

The most noteworthy result of the analytical work is that in no case was as much as 2 per cent. of magnesium found. The highest result was 1.86 per cent. in the soft sheet. This result was obtained by precipitating (twice) the magnesium as the double phosphate from an alkaline solution in which the aluminium was retained by the presence of alkali tartrates. But I have reason to believe that this result is too high. The alloy dissolves very vigorously even in diluted hydrochloric acid, and considerable care is needed in this operation. It is little affected by nitric acid.

Zisium and Ziskon.

"Zisium" and "ziskon" are two light alloys prepared for use primarily in scientific instrument making. Zisium was first named zalum, but it was found that this name could not be registered. Both alloys are silver-white in colour and make good castings, in which form only they are supplied.

Zisium is the lighter, having a density of 2.95 as compared with 3.35 for ziskon. The latter is, however, much harder and stronger. The tensile strength of the metals (cast in sand) is stated to be nearly five and 11 tons per square inch respectively, according to tests made at the National Physical Laboratory. My experience of their working properties is confined to the making of turnings for the purpose of analysis. Zisium cuts like very soft brass, in short curly chips, using a tool as described for magnalium. Ziskon seems to have a texture resembling that of cast-steel, though, of course, much softer. It needs to be cut at a lower speed than zisium and gives long shavings.

Want of time has prevented my doing more than making a qualitative analysis of each of the two sample castings of these alloys which I have had. The results show, as might be expected, from the specific gravity, that both are aluminium alloys. Zisium, like magnalium, appears to be essentially aluminium, modified by the presence of small amounts of other metals. I find in it zinc, tin, and copper, with a trace of antimony, and a minute trace of bismuth and possibly thallium.

Ziskon has a different character. It is a zinc-aluminium alloy, containing perhaps one-fourth its weight of the former metal, as far as could be judged by a rough weighing of the zinc sulphide obtained in the qualitative analysis.

Other Aluminium Alloys.

Zinc-aluminium alloys have been studied by Mr. J. W. Richards. He confirms the previous statements of Durand as to the remarkable

mechanical properties of one containing one-third of its weight of zinc. It is very hard, resembling tool-steel, and its specific gravity is given as 3.8. On the other hand, alloys containing only one-sixth of zinc or less are soft enough for rolling or drawing. An alloy intermediate in composition, containing 25 per cent. of zinc, is said to give excellent castings, easily worked, and to be much used for scientific instrument making. Its specific gravity is given as 3.4, thus closely agreeing with that of ziskon. These statements, I think, confirm the result of my examination of ziskon.

A great many other aluminium alloys, containing such metals as zinc, copper, nickel, and tungsten, have been patented in recent years, and some are in actual commercial use.

The numerous aluminium bronzes do not come within the scope of this paper, as they are not light alloys, since aluminium is not their principal constituent.

In conclusion, I must express my indebtedness to Mr. J. B. Murray for a great deal of valuable assistance, and to Mr. J. Arthur Williams, of Hatton Garden, who has rendered indispensable help in the supply of specimens and information.

R. E. BARNETT, B.Sc.

Discussion.

Mr. C. P. Finn asked if Mr. Barnett had made experiments towards the examination of magnalium by micrographic methods of analysis. The results of such an examination of the structural changes produced in the alloy by chilling, etc., would be of great interest. What method should be used in soldering magnalium? How did the co-efficient of expansion of the alloy compare with that of aluminium?

Mr. J. W. Cobb said the alloy appeared to be soft, and so would easily scratch and flow, and be difficult to polish. Decreasing hardness made polishing increasingly difficult, as for example in the case of lead. This would, no doubt, interfere with the obtaining of polished surfaces suitable for photo-micrographic study. Were the aluminium laboratory paints used to prevent corrosion of apparatus, etc., analogous in composition to magnalium? He could appreciate the difficulties of securing good separations by double precipitation, as, in analysing magnesite, he had found three or four precipitations necessary to secure satisfactory results. Since small quantities of molybdenum and tungsten converted steel into a high-speed cutting steel, with special properties, the presence of titanium even in small quantity might produce its own effect in magnalium. For this reason, he thought it should not be concluded, that because the titanium was probably introduced through the bauxite, from which aluminium was extracted, it would not have some effect on the properties of the alloy.

Mr. T. Fairley suggested that there was a possibility of the amount of magnesium in the alloy, diminishing in the working or casting. If 2 per cent. were originally present, the final percentage might be much lower owing to oxidation by the atmosphere during heating. He had given students analyses of aluminium paints for exercises in examinations, and in certain cases the results showed the presence of about 3 per cent. of tin. He supposed magnalium, like aluminium, was affected by caustic alkalis.

Mr. F. W. Branson said, that while at King's College he came across an aluminium alloy which contained a little silver.

Mr. R. E. Barnett said he had done nothing to test the suitability of magnalium for photo-micrographic study, and had seen nothing on this point in any description of the alloy. He thought Mr. Cobb's view would be correct. In turning the metal, the remarkably even surface suggested that it flowed in front of the cutting tool. To get a surface for metallography, he thought something like casting on to glass, and then breaking away the latter, might have to be resorted to. The alloy would have to be soldered like aluminium;

flux should be used, but a special solder of aluminium with some other metals. Scraping under the molten solder with the bit, or even with a wire brush, would be necessary to remove oxide. Other alloys of aluminium and magnesium, such as magnalium powder used for flash light purposes, probably contained more magnesium. The analytical results were curious, showing remarkably low percentages of magnesium, and there were puzzling discrepancies between these results and published statements. If the amount of magnesium originally put into the alloy was the published percentage, this discrepancy might be explained by Mr. Fairley's suggestion, that the magnesium was lost through oxidation in the heating and preparation of the alloy.

ADVERTISING FOR PHOTOGRAPHERS.

"SCANDLIN'S Business Brieflets" is the title of a smartly written little pamphlet which reaches us from 345, Sixth Avenue, Brooklyn, New York. The author of the "brieflets" is Mr. W. I. Scandlin, well-known in American photographic circles, and now describing himself as "Specialist in Advertising for Photographers." The contents of the little book are so good, and so much to the same point as that advocated in our recent series of articles on advertising for photographers, that we venture to quote a few of the happy paragraphs. For instance:—

"You know how to make a good photograph; it does not follow that you know how to make the public believe it. You have only to convince the public that this is so and the public will pay your price for it, your stock bills, your help, and, if you convince it hard enough, it will buy you an automobile or a yacht—both, if you want both. Good advertising is the only salvation of photography to-day. The technique is good enough, but business is not. Good advertising will improve the only weak spot in the business.

"A good business man is like a good fisherman. Both throw out a large bait and then leave it up to the fish to bite. If you could catch one-fifth of the people of your community who haven't been in a gallery for five years, you would be kept busy. A lot of them will rise to the right kind of bait. Why not go fishing?"

"The right kind of publicity will increase the profit of a business the right kind of fertiliser will increase a crop. Probably not one in twenty of your community is photographed once in every two years. If one in ten could be brought to the studio once every second year, or one in twenty induced to come once each year the business of every studio in your community would be doubled. If the publicity that doubled the total volume of business comes from your studio alone, your share will be more than doubled. There is a profitable business in the future for the photographic studio that will after it in the same business-like way that others employ.

"You may as well try to run a photographic gallery without water without publicity. It can't be done in these days. If you don't talk about your own work, and if you don't keep constantly before the people of your community, they will forget you when they get ready for a sitting. They will go to the other fellow who has been hammering his name into their minds while you have been sleeping (?) a few dollars.

"If your business is fair without publicity it may be prosperous without it.

"Publicity of the right kind may be made profitable in any business.

"The public loves dainty illustrations. The photographic studio can supply an endless variety. Illustrated studio booklets are effective and logical methods of publicity.

"If you want people to know of your existence it's better to remind the same person three or four times, than three or four times many persons once. A billion drops of water falling on the same

spot will wear away solid rock. The same quantity, poured from a bucket over its entire surface won't make an impression.

"We pay too much attention to making photographs and far too little to making a demand for them.

"A large part of every additional dollar's worth of business you can do, without increasing your help, is velvet. If you can get a few more people coming your way each month, you'll soon note a difference.

"A two line reading notice in your local paper is often worth more to you than a four-inch space in the advertising pages. A bunch of short, bright locals costs little.

"A genuinely 'swell' booklet given out to your best people makes them think that you are the man to give them the best satisfaction when they want photographs. It also reminds them that they need some right now. These two thoughts ought always to be harnessed together."

Needless to say, Mr. Scandlin takes care to impress upon his readers the fact that he is the right man to prepare advertisement matter for those who cannot successfully undertake it themselves; and a gentle hint to that effect is embodied in most of the "brieflets," as for example:—

"It isn't that people don't want photographs, it's simply that they don't realise the need. They must be reminded. Keep the thought of photographs, your photographs, constantly before them. Let them see your name on your work or something that shall suggest your studio on every possible occasion. If you don't know how to remind a person of the same thing in fifty-seven varieties of style and finish, try Scandlin. He does.

FORTHCOMING EXHIBITIONS.

August 24 to September 21.—Berwick-upon-Tweed Arts Club. Hon. Secretary Pictorial Photography Section, H. Hancocks, 38, Ravensdowne, Berwick-upon-Tweed.

September 8.—International Exhibition at Budapest. Address, Secretary of the Photo-Club, Egyetem-ter 5, Budapest, IV.

September 15-October 21.—Photographic Salon, 5a, Pall Mall East. Hon. Secretary, Reginald Craigie, Camera Club, Charing Cross Road, W.C.

September 21-October 28.—Royal Photographic Society, New Gallery, 121, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

October 17-18-19.—Isle of Wight Photographic Society. Hon. Sec., V. Howard Burgess, 53, Pyle Street, Newport, I. of W.

October 18-21. Rotherham Photographic Society. Hon. Secretary, H. C. Hemmingway, Tooker Road, Rotherham.

October 19-21.—Grangemouth Amateur Photographic Association. Hon. Secretary, Robert Marshall, 3, Park Terrace, Grangemouth.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

November.—Edinburgh University C.C. Hon. Secretary, Harold C. Simpson, University Union, Edinburgh.

November.—Bristol and Clifton Arts and Crafts Society. Secretary, R. H. Parr, 5, Grove Buildings, Blackboy Hill, Bristol.

November, December, January.—Second American Photographic Salon. H. Snowden Ward, 6, Farrington Avenue, London, E.C.; Wm. T. Knox, 279, Washington Street, New York City, U.S.A.

November 3, 4, 5.—Motherwell Young Men's Institute C.C. Hon. Secretaries, James Dunlop, Myrtlebank, Motherwell, and Archibald Matthews, 24, Enfield Place, Ladywell, Motherwell.

November 8-15.—Croydon Camera Club. Hon. Sec., W. H. Rogers, 88, Woodville Road, Thornton Heath.

November 14, 15, 16.—Ipswich Camera Club. Hon. Sec., R. H. Sutton, 37, Henley Road, Ipswich.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

November 25-December 2.—Glasgow Eastern A.Ph.A. Hon. Secretaries, Thomas B. Kirkhope, 37, Winston Street, Parkhead, Glasgow, and John Brough, 68, Dalmarock Street, Parkhead, Glasgow.

December.—Muirkirk A.Ph.A. Hon. Secretary, William Barrowman, Ayr View, Muirkirk.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 6-7.—Watford Camera Club. Hon. Secretary, E. H. Jackson, 100, High Street, Watford.

December 12.—The Scottish Photographic Federation Lantern Slide Competition. Entries to Hon. Secretary, John B. MacLachlan, Blairgowrie.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

December-January.—Wishaw Ph.A. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January, 1906.—Shettleston Camera Club. Hon. Secretary, Wm. Kitson, Hawthorne Villa, Shettleston.

January 13-February 3, 1906.—The Third Scottish National Salon at Dundee. Hon. Secretary, V. C. Baird, Broughty Ferry. Entries close December 30, 1905.

February 3-February 25, 1906. Marseilles Fourth International Salon. M. Astrer, Sec. Gen., 11, Rue de la Grande-Armée, Marseilles.

February 13-27, 1906.—Greenock C.C. Hon. Secretary, W. D. Boyd, 2, Church Place, Greenock.

March, 1906.—Larkhall C.C. Hon. Secretary, Robert Rodger, 26, M'Neill Street, Larkhall.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern P.A. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 19-24, 1906. Sunderland Photographic Association. Hon. Sec., William E. Kieffer, Stirling Street, Sunderland.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 1, 1906.—Coatbridge Co.-Op. C.C. Hon. Secretary, James Robb, 6, Windsor Terrace, Blenheim, Coatbridge.

FORTHCOMING COMPETITIONS.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 in prizes for photographs taken with Thornton-Pickard cameras or shutters.

October 15.—Lantern Slide Competition, Association Belge de Photographie. Secretary, Palais du Midi, Brussels.

October 31.—"Zigo." Cash prizes for prints on "Zigo" self-toning paper. Thos. Illingworth and Co., Limited, Willesden Junction, London, N.W.

November 30.—Royal Photographic Society "Affiliation" Print Competition. Particulars from the Secretary, 66, Russell Square, W.C.

December 30.—Royal Photographic Society "Affiliation" Lecture Competition: (a) Illustrated lecture descriptive of a tour; (b) Illustrated technical lecture. Particulars from the Secretary R.P.S., 66, Russell Square, London, W.C.

February 6-9, 1906.—Guisbrough Fine Art and Industrial Society, Photographic Section. Hon. Sec., G. H. Angus, 34, Westgate, Guisbrough.

Photo-Mechanical Notes.

Intensifying Collotype Negatives.

PROFESSOR R. NAMIAS advises, in the "Zeitschrift für Reproduktions-technik," a process of intensification which can be employed in conjunction with the stripping method, introduced by him, in which the gelatine film is treated first with basic chrome alum and afterwards with an acidified solution of a fluoride. It is found, however, that negatives intensified with mercury are more or less reduced by the basic chrome alum, whatever darkening reagent be employed. On this account the following procedure is adopted:—The negative is bleached in the ordinary mercuric chloride solution, and thoroughly washed; if a considerable intensification is required, a little potassium bromide may be added. The bleached and washed negative is then treated in the basic chrome alum solution, and then in the acidified fluoride. The detached film is washed in clean water, and then transferred to weak ammonia, in which it blackens. It is then attached, with a solution of gelatine, 1 to 2 per cent. in strength, to its final support of glass or celluloid.

Professor Namias finds that the mercuric iodide intensifier is not open to the objection that the results are altered by the chrome alum, but he considers that the intensification by this process is too great, and unsuitable for collotype, a view from which one may legitimately dissent.

Reverse Blocks.

Writing to the "Illustrator," the official journal of the International Photo-Engravers' Union, G. S. Busk says:—When you have a line job and want a reverse of it, such as black background and white letters from a regular drawing or printed type, you do not have to make a negative and a positive from it and make your print, but make your negative, then coat your zinc with a good coating of sensitizer and make a print as usual and ink up. Develop in the regular way, then grain or frost, in very weak nitric acid, wash off ink with turpentine and cotton, so as to be sure it is clean, and then ink up as though you had just made a print, and develop in four ounces of muriatic acid, twelve to fourteen ounces of water, as though you were just developing first print again. Where the lines were black they will come up white and leave black background, and the same if you have black background, you can make black letters and white background.

Autochromes.

Although this name is protected, the process is not, and it is also known as "autocolour," "combination," etc., and is chiefly used in Germany, according to Herr Bauer, for the production of pictorial postcards, of which from twenty-five to thirty are printed at once on one sheet. Imperfect originals and bad photographs are more often received than not, and therefore they are worked up or faked, and this is best done with an aerograph as follows:—A mask of tracing paper is cut out, so that it shall cover all those parts which are not to be worked up and accurately fitted to the print. Then a light grey wash is evenly put on with the aerograph, and then, after the removal of the mask, the outlines corrected. A broad brush must be used if one has not an air brush, but the work is more difficult. On many cards the sky is cut completely away in the half-tone plate, but this should not be done, as the cross-lines add a grey to the blue, which then harmonises better with the distance. For making the negatives a screen of from 70 to 80 lines per centimetre is used. Two or four originals are generally reduced at once, but they must all be about the same tone. The negative should be rich in contrast, but the dots should show, even in the deepest shadows. Printing is done as usual on zinc or copper, and in etching

care must be taken to keep the drawing and bright parts, particularly the sky, light. From the finished plate the so-called "klatsche" is prepared, as in ordinary lithography, and on papers with different grains for each colour. The chromolithographer now draws the yellow plate on coarse-grained paper with chemical chalk and ink, the red on a finer grain, and the blue on the finest grained paper. With these three colours perfect colour rendering and effects are obtainable. It is better and simpler to fasten transparent grain paper on the black half-tone pull and to lay the colours on this. Only white or glazed or chromo cards are used. The "klatsche" is transferred to stone, and from this further transfers made and etched according to the black half-tone pull. In order to obviate the use of grained paper, the prints can be made on ordinary transfer paper, and then transferred to stones of different grains, and for photographers this may be more convenient. The autochrome process will give excellent results, and may be used for ordinary illustration purposes, if absolutely faithful colour rendering is not required but rather the embellishment of a monochrome image by colour.

Spray Etching Plates.

An apparatus for applying an etching fluid to a plate has been worked out and patented by Mark Smith, of the Guardian Printing Works, Reddish, by whom absence of undercut, with other advantages, are claimed for the method. As described in the specification No. 25,744, 1904, the etching chamber contains a rotating brush (c) which throws a spray of acid against the plate (h), which latter may be held horizontally film downwards, as shown in the figure, or inclined at any suitable angle.

Spray Etching.

The liquid which is thus sprayed against the under face of the plate drops or runs off and falls to the bottom of the tank for re-use, draining to the well (a') if such well be employed. The liquid may be renewed as desired.

When the etching has progressed sufficiently the plate may be moved, either for finishing or for further treatment.

A flat plate has been indicated as under treatment, but a curved cylindrical or partly cylindrical plate may also be etched, such plate preferably having rotary motion imparted to it during the spraying. With such a plate the best result would be obtained by screening the cylindrical plate from the indiscriminate action of the spray by means of a screen placed below the cylinder, such screen being formed with a narrow opening extending the length of the cylinder and about parallel to its axis.

A New Matrix for "Electros."

Casein and albumen are mentioned as new materials for the formation of a matrix from printing blocks, and the plastic mass of which one or other of these substances forms the chief constituent is said to take impressions very readily, and to shrink very little. The casein or albumen is employed in conjunction with a hardening material, after it has first been moistened with a liquid which does not completely dissolve it. Hexamethylenetetramine has been

found particularly suitable as a hardening agent. A number of formulæ for suitable mixtures are given in the patent specification (No. 27,090, 1904), in which the inventor, Louis Collardon, of 32, Friedrich Liststrasse, Leipsic, describes his process: In preparing a printing block the procedure is the same as in the formation of celluloid "electros," the somewhat softer casein or albumen plate being rendered plastic by heat or steam, applied speedily to the cold matrix, impressed with a sharp pressure and allowed to cool.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes.

The following applications for patents were made between August 14 to 19, 1905:—

PRINTING FRAME.—No. 15,526. A gaslight postcard printing frame. William Wilkinson, 21, Silver Street, Durham.

DEVELOPING.—No. 16,576. Improvements in developing apparatus for photographic plates. Jesse Dougherty Lyon, 18, Southampton Buildings, Chancery Lane, London.

SHUTTER.—No. 16,593. Curtain shutter for photographic cameras. Ernst Branburger and Optische Anstalt, C.P., Goerz Act. Ges., 31, Bedford Street, Strand, London.

ELECTRO-PHOTOTELEGRAPHY.—No. 16,796. Improvements in devices for electrographical long-distance transmission and the reception of drawings, photographs, and the like. Herr Carbonnelle, 322, High Holborn, London.

CAMERAS.—No. 16,857. Improvements in photographic cameras. Arthur Samuel Newman and Newman and Guardia, Limited, 115, Cannon Street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

DAYLIGHT LOADING PLATE CAMERA.—No. 17,155, 1904. A magazine camera to receive, in daylight, a charge of sensitised plates, to carry a focussing screen, to convey successively the several plates from the magazine to the exposure chamber and, in the transference,

to cause the plate to automatically displace the focussing screen and occupy the situation thereof and, after exposure, to drop into a vessel containing a developing solution from which it is enabled to be transferred to a bath containing the fixing solution;

the entire operation being adapted to be performed without recourse to a dark room. The apparatus is specially adapted for the production of ferrotype positives, and an important form of construction will be one suitable for taking miniatures. *A* is the magazine chamber, receiving a charge of sensitised plates contained in a case *c*; *f* is the exposure chamber, fitted with a lens, *g*, and focussing screen, *h*. Beneath the camera case, comprising the magazine and exposure chambers, is movably mounted a vessel formed with two compartments *q*¹ *q*². This vessel may be mounted to slide in guides, but preferably it is pivoted in such a way as to turn in a horizontal plane about a vertical axis *r*. The movable solution-holding vessel contains a cradle *s* perforated at the bottom, which cradle is adapted to receive the plate just previously exposed and facilitate the transference from the compartment *q*¹ to the compartment *q*² when the vessel has been temporarily withdrawn from the home position beneath the camera case. The specification describes the mechanism whereby the plate is transferred to the exposing chamber and thence for development and fixation. Herbert Edward Hickon, 297, Haydon's Road, Wimbledon, Surrey.

DARK SLIDES FOR COLOUR PHOTOGRAPHY.—No. 20,827, 1904. The patent is for a dark slide permitting the rapid changing of plates and filters used in the three-colour process. A carrier, *a*, having two compartments *b* and *c* slides in the grooved frame *d* the inner length of the groove being equal to one and a half times the length of the carrier *a*. The frame *d* is covered in behind as at *e*, and also at one-third of its length from one end in front as at *f*, and is provided with the usual draw-shutter *g* at the other end, a stop being provided to prevent it being drawn out further than to expose that one of the compartments *a* and *b* which is at the moment at the centre of the length of the frame *d*, and any suitable means may be employed for bring-

ing the compartments *a* and *b* successively into this central position. A simple and convenient means for thus centralising the compartments consists in providing a longitudinal slot *h* in the back cover *e* in which is free to move a headed pin *i* attached to the centre of the back of the carrier *a*, the length of the slot *h* being such that when the pin *i* is at one extremity of the slot *h* the compartment *b* will be central, and when at the other end the other compartment *c* will be in that position. In the compartment *b* is inserted a red-sensitive plate with a red filter in front of it, the two being held in place by the catches *j* or any other suitable means and kept in register by the back springs *j*. In *c* is inserted first a green-sensitive plate, then a green filter, and outside of this an ordinary sensitive plate, face inwards. The slide is inserted in the camera, the shutter drawn, the pin *i* moved to one end of the slot *b*, the lens uncapped and the exposure made, which is suited to the sensitive plate in position. The lens is again capped and the pin run to the other end of the slot, the lens uncapped, and an exposure made on the contents of the other compartment of the carrier. Benjamin Jumeaux, Colebrook Road, Southwick, Sussex.

COLOUR PHOTOGRAPHY ON PAPER.—No. 21,208, 1904. The claim is for a "carbon transfer paper," consisting of a flexible support, a film of coloured soluble gelatine, and a film of easily soluble

matter between the two. The upper layer consists of gelatine with perchloride of iron and tartaric acid, and is insoluble until exposed to light. The intermediate coating is of gum, albumen, wax or varnish. Once the carbon transfer paper is made, it may be used at any time; since the colour is fixed, the paper may be wetted in cold water and be squeegeed on the surface on which it is to be printed. After being squeegeed upon the last-mentioned surface, the paper is removed, leaving an absolutely uniform film of a predetermined colour ready to be sensitised and printed under the negative, after which the unacted-upon parts are removed. After impermeabilisation or other protection of the print so made, another film may be squeegeed upon the support, overlying the first, and is then sensitised, printed, developed, and washed without staining the underlying image or print, since the second film is put on cold. After the impermeabilisation or other protection of the second print, a third film may be transferred in like manner upon the support and be sensitised, printed, etc., thus giving a final composite print in which no one film is stained or discoloured by another. In the old method, where the films are poured on hot, staining is very likely to result, and it is very difficult, if not impossible, to determine whether the film is uniform in colour or not, the presence of the images in other colours interfering with proper observations. Charles Louis Adrien Brasseur, 10, East Fifteenth Street, New York, U.S.A.

COLOUR-SCREEN HOLDERS.—No. 21,209, 1904. The claim is for a construction of screen holder, by which the screen can be pressed into actual contact with the photographic plate. Charles Louis Adrien Brasseur, 10, East Fifteenth Street, New York, U.S.A.

ALARM CLOCKS.—No. 22,221, 1904. The invention, which requires a number of figures for its explanation, consists in adapting an ordinary alarm clock so that it may be set in the dark by the sense of touch or by sound to give an alarm after predetermined intervals of time as used in photography, and also to cause an alarm at a distance by closing an electric circuit and ringing a bell, or causing the armature of its magnet to operate the release of the shutters of a photographic camera. Benjamin William Warwick, 104, Highbury Hill, London, N.

TRIPODS.—No. 23, 1905. The patent describes a construction of tripod in which a control rod slides through the head, and can be fixed in any position, thus serving the purpose of a taller tripod. The legs are separately adjustable, and held rigidly in position by a system of struts. The lower points of the legs may be spread out, as desired, by lowering (or raising) the central rod, and thus bringing the struts more or less near to a level position. The telescopic adjustment of each leg is therefore independent of each other, and also independent of the central pillar and the struts, so that when the stand is used in places where the ground is very uneven, any one or more of such legs may be lengthened or shortened to any extent to accommodate such unevenness. The whole arrangement folds into a small space. James Ashford, 179, Aston Road, Birmingham.

CHANGING FILMS.—No. 9,323, 1905. The specification describes (with fifteen figures) a system of changing films in daylight adaptable to ordinary apparatus, and embodied in a case containing a light receiver and a film magazine, and an exposing chamber into which the films pass before removal from the camera. Julien Charpentier, 20, Rue Delambre, Paris.

DAYLIGHT DEVELOPMENT.—No. 9,806, 1905. Describes a tank for development, the novel feature apparently being the rounded and weighted base on which the tank stands upright, or on which it can rock. Edward Rosell Petrie, 76, Second Place Brooklyn, New York, U.S.A.

New Apparatus, &c.

Cherrill Printing Frame. Sold by Houghtons, Limited, 88 and 89, High Holborn, London, W.C.

This printing frame which has been put on the market primarily in the interests of "pictorial photographers" is of ingenious construction, and, doubtless, in the hands of the photographer who wishes to "control" his negative or printing process, will be of great use. By a system of notches and pins perfect registration is assured between paper and negative, even after the entire removal of the former from the frame. This is achieved by the negative being affixed by a specially prepared adhesive medium to the back of the printing frame, which can be taken in one piece from the frame and replaced in exactly the same position it formerly occupied after the negative has also been removed and masked, or otherwise "controlled." To the worker in the gum-bichromate process it should specially appeal. The chief difficulty in multiple printing with this process appears to be in obtaining exact registration after each coating. With the Cherrill frame this drawback can be overcome without further trouble, and as modifications can be made, not only to the print but also to the negative in printing, the pictorial photographer will be able to achieve an endless variety of effects with this reliable piece of apparatus. He will also take heart of grace from some of the illustrations in the book of instructions, in which the fundamental laws of pictorialism are well set forth. For instance:—"It is evident that by the alternate use of masks made as indicated any amount of control may be exercised, so that the resulting print may be made to assume a character totally different from that which could be obtained in an ordinary printing frame. . . . It is possible from an artistic point of view, desirable to reduce the excessive coarseness and painfully cut detail so often found in negatives made with modern high-class lenses."

It is, however, in combination printing, that is, in producing a print made up from parts of several different negatives, that the Cherrill frame is most likely to score. The frames are made with every part interchangeable, so with a series of frames, each containing a different negative and suitable masks, the print, affixed to the back of the first frame, can be placed in register over each negative in turn until the complete picture has been secured. Needless to say for work of such precision the frames are well made, and the price for printing from negatives up to whole plate is 12s. 6d. includes negative and mask carriers, etc.

"Tress" Rapid Bromide Printer. Made by the Tress Company, 205, Oxford Street, W.

This latest introduction by the Tress Company embodies several features of novelty that should appeal to the busy worker, or to the photographer who desires to rapidly produce proofs for customers' selection. Indeed, the claim made for this piece of apparatus, that it is the only machine of its kind specially designed for the production of prints from the wet negative "while you wait," appears to be fairly substantiated. The apparatus is not only ingenious, but its simplicity is a great point in its favour. In construction it is a box about ten inches cube with a removable top panel, which forms the printing frame with hinged back. This printing frame takes carriers to hold any size negative up to half-plate. In the bottom of the box is fixed a four-volt electric lamp and reflector. This lamp is supplied by a small battery contained inside the box. Contact is made with the negative by means of a metal spring fixed in the rebate in which the printing frame rests, but the weight of the frame is taken by four other springs placed at intervals round the rebate. When the negative

and bromide paper are in position in the top frame, it is only necessary to press this part down (a matter of half an inch), the contact is made, the lamp lights, and the exposure is complete in about three seconds with a negative of ordinary density. By removing the pressure of the hand, the top frame returns to its original position, the contact is broken, and the light goes out. The delightful simplicity of this exposing machine has only to be tried to be appreciated. For exposing wet negatives, sheets of thin celluloid are supplied. The negative is taken from the fixing bath, slightly rinsed, and placed in the carrier of the printing frame. A sheet of the celluloid is now placed over the wet film and a piece of dry bromide paper placed in position on this. The hinged back is returned to its place, and the whole frame pressed down into the box for three seconds. After the exposure, the bromide paper is removed and developed in the ordinary way, and the celluloid is taken off the negative, which then receives complete washing; or many other prints can be obtained from the wet negative, without in any way injuring it. The apparatus costs £1 17s. 6d., and the lamp, which will burn for five hours continuously, can be recharged for a few pence.

We have received three sets of "Keene's Nature Studies," published by Mrs. M. Keene, 95, Egerton Road, Bristol. They include reproductions from original photographs of budding plants, flowers, fruits and seeds in various stages of growth, also birds and their nests and other natural history subjects. The sets are published at 2s. 6d. each, and the complete series contain thirty different studies. The prints are excellently produced, and depict the various subjects in a manner that will render them of undoubted educational value. The plates are $8\frac{1}{2}$ by $6\frac{1}{2}$ in size, and are printed with broad white margin. We understand that these studies are being used already at the leading British and colonial schools, and are highly recommended by eminent educationalists.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
4.....	South London Photo. Society ...	{ Opening of Winter Session and Conversation.
4.....	Bowes Pk. and Dis. Ph. Soc. ...	{ Competition of Chisford Marshes
5.....	Manchester Amat. Photo. Soc. ...	{ Outing Prints. Lecture, "Bromide Enlarging," Mr. H. C. Bird.
5.....	Rotherham Photo. Society	{ "Making Enlargements." Mr. C. J. Atkinson.
		{ Lecture on "Crystallisation." Mr. J. Leadbeater.

ABERDEEN PHOTO ART CLUB.—This club held its annual business meeting at 62, Fonthill Road, on Friday evening last. Mr. G. L. Smith occupied the chair. The secretary and treasurer's report showed the club to be in a satisfactory condition both financially and in membership. The following were nominated and elected for the ensuing year:—President, Mr. G. L. Smith; vice-presidents, Messrs. Jarvis and Dalgity; lanternist, Mr. Stephen; assistant lanternist, Mr. Bow; secretary and treasurer, Miss Dalgity; assistant secretary, Miss M. R. Smith; committee—Messrs. Stephen, Bow, Christian, and Mundie; Misses M. M. Thomson, Grant, Smith, and Clerihew.

CAPE TOWN PHOTOGRAPHIC SOCIETY.—The annual meeting of this society was held on August 3, in the Oak Hall, Y.M.C.A. Buildings, Cape Town, under the presidency of Professor W. S. Logeman. The secretary (Mr. A. J. Fuller) read the 15th annual report, which was

very satisfactory. He said:—"Considering the very great business depression which has prevailed in the Colony since the last annual meeting, the prosperity of the society is phenomenal, for the membership keeps up well, and the meetings during the year had been far better attended than during any previous year. The educational advantages arising from the exhibition which was held in the Easter week in 1904 are becoming more noticeable by the increased earnestness of many of the members, and the character of the work which is now being done by them, and although the exhibition cost the society a considerable sum, yet it has turned out to have been money well and usefully spent, having regard to the objects of the society." The forthcoming exhibition and its extent were then discussed, and the events of the past year reviewed, including the visit of the secretary and Mr. J. P. Edwards to England to the Photographic Convention and the conversazione given in their honour on their return. Lectures from the R. P. S. had been read, and the thanks of the society were due to the authorities of the South African College for the use of their laboratory and lecture-room for demonstration purposes, and to the board of the Y.M.C.A. for the continued use of their building. Mr. Fuller further said:—"The efforts of the Copyright Section have been rewarded by the passing of a Copyright Bill for the Colony during the last session of Parliament, but unfortunately, through the long delay of the Government in putting it into force, the members have not yet been able to avail themselves of its much needed provisions; this is the more to be regretted as several members have suffered considerable pecuniary loss thereby, and unless this is speedily rectified it may seriously interfere with the success of the forthcoming exhibition." The chairman said that the society was lucky in having such a secretary as Mr. Fuller. In the name of the committee he had been empowered to ask for permission to present £25 to Mr. Fuller as a token of gratitude. That would not be anything in the shape of a salary, but simply as a token of appreciation. The following were elected office-bearers for the current year:—President, Sir David Gill, K.C.B., F.R.S.; vice-presidents, Mr. J. D. Cartwright, M.L.A., Rev. W. Forbes, Mr. E. Noakes, and Professor W. S. Logeman; committee, J. P. Edwards, H. S. Jaegar, E. Naude, E. C. Matson, E. H. Oakley, H. W. Schonegevel, E. J. Steer, P. Mowbray Turquand; lanternist, G. Ainslie; secretary and treasurer, A. J. Fuller. The membership of the society now numbers about 190.

THE death is reported of Mr. Alex. B. Cunninghame, of Blaydon, which took place at Brotton, near Saltburn. Mr. Cunninghame was very well known in local photographic circles, having held the position of honorary secretary of the Blaydon and District Camera Club for several years. Deceased was also one of the prime movers in the formation of the Federation of the Photographic Societies of Northumberland and Durham some four years ago and has since served on the Council of that body. He was only thirty-five years of age.

SNAPSHOTS on a Cowcatcher.—Mr. C. R. Noble has just returned to London with 18,000 ft. of films, after a tour through the wilds of South America in search of photographic copy for the Urbanora Bioscope Company. In order to photograph the scenery the enterprising photographer travelled across the Andes to Paraguay on a cowcatcher.

TRIBUTE to a Dead Queen.—According to the "Daily Mail," Sir Benjamin Stone, M.P., paid a visit to Peterborough Cathedral on Saturday, where he was much interested in the tomb of Catherine of Aragon, first wife of Henry VIII. Sending out to a florist, he ordered a mass of lovely flowers, which he arranged over the tomb, and then photographed it.

Commercial & Legal Intelligence

MIDLAND Camera Company Limited.—This company has just been registered with a capital of £10,000, in £1 shares, to acquire the business carried on at 64 and 73, Slaney Street, Birmingham, as the Midland Camera Company, to adopt an agreement with C. How and G. L. Moore, and to carry on the business of manufacturers of photographic cameras, apparatus, materials, accessories, etc.

A COMMERCIAL Traveller.—At the Bristol Bankruptcy Court Frederick Ernest Etches, of Berkeley Road, Westbury Park, Bristol, appeared on a bankruptcy petition. A deficiency of £529 was shown, liabilities to rank at £336. The alleged causes of failure were "Insufficient capital to properly work my business, the out-of-pocket expenses of which are heavy." The bankrupt, who is thirty-three years of age, stated that for some years he had been manager for several photographic publishers, but began trading on his own account in March of this year, with a capital of £100 borrowed from a friend, and which was still owing. The bankrupt on May 23 last borrowed £40 upon bill of sale, the security given consisting of household furniture, some of which was not paid for, and a motor-car which he used for the purposes of his business in travelling about the country taking photographs.

PHOTOGRAPHER'S Canvasser Pawns a Camera.—At Aberdeen on August 22, Charles Paterson, photographer's canvasser, of 78, Rosemount Viaduct, was charged with having, on August 18, in a shop 178, Rosemount Place, occupied by James Rennie, photographer, received a camera from Rennie in order that he might show it to a customer, but which he pawned. Accused, who had been previously convicted, pleaded guilty, and said he was drunk at the time. The Sheriff said this was another act of the same sort the accused had been carrying on since November, 1898, and he had had plenty of warning. He would have to go to prison for sixty days.

MILITARY Raid on Photographer's Tent.—At the Lincoln County Court on August 23, Thomas Gilbert Hickingbottom, publisher and photographer, of Lincoln, sued Sergeant E. A. Parker and Sergeant J. A. Kelly, of the Lincoln Militia, for £3 15s. 8d., damage done to his photographer's tent. The plaintiff had established himself in a tent at the encampment at Louth where he was taking photographs. One night when he had left the tent in charge of two friends, the defendants came up in a state of hilarity. They threw his chemicals about and damaged the tent. His Honour, in giving judgment to the plaintiff, expressed very great surprise that the adjutant was not present in court. He believed the War Office had given order that some officer must be present to represent the regiment at a trial.

PHOTOGRAPHIC Lenses.—In the Court of Chancery on the 1st August, Messrs. Perken, Son and Company, Limited, of No. 1, Hatton Garden, London, wholesale opticians and manufacturers of scientific instruments, brought an action against the firm of Brickell and Jones, of 259, High Road, Brondesbury, London, wherein they claimed an injunction restraining them from offering for sale or passing off as the goods of Perken, Son and Company, Limited, any lenses or other photographic apparatus which were of inferior quality or foreign manufacture, and not manufactured by Perken, Son and Company, Limited, and from representing, or causing to be represented, the lenses and other photographic apparatus not manufactured by Perken, Son and Company, Limited, but sold by Messrs. Brickell and Jones as the manufacture of Perken, Son, and Company, Limited. It was ordered by his lordship, Mr. Justice Warrington, and with the consent of the defendants and their counsel, that the motion for injunction should be treated as a motion for judgment and the defendants, by their counsel, giving a perpetual undertaking. It was ordered that Messrs. Brickell and Jones do not sell or offer for sale or pass off as the goods of Perken, Son and Company, Limited,

lenses or other photographic apparatus which were of an inferior quality and of foreign make (and not manufactured by Perken, Son and Company, Limited) as the lenses or other photographic apparatus manufactured by the plaintiffs. And not to sell or offer for sale the lenses or other photographic apparatus manufactured by Perken, Son and Company, Limited, under the prices fixed by them in their trade discount lists, catalogues, or invoices furnished to Messrs. Brickell and Jones, and not to print, publish, issue, circulate, or distribute any catalogues, circulars, or price lists containing any plates or illustrations or descriptions of lenses or other photographic apparatus manufactured by Perken, Son and Company, Limited. The defendants were ordered to pay the costs of the action and 40s. damages.

ALLEGED ARTFUL SWINDLE.—At the Lambeth Police Court on Saturday last, Henry Andrew Spinney, describing himself as a clerk, of Somerleyton Road, Brixton, was charged with stealing, by means of a trick, 60 oz. of silver nitrate, value £5, the property of Messrs. John Griffin and Sons, Limited, of Sardinia Street, Lincoln's Inn Fields. On Friday morning last they received a telephonic message, in consequence of which they sent Mr. H. W. Apperton, a young clerk in their service, to a house in Valentia Road, Brixton, with 60 oz. of silver nitrate and 1 lb. of cotton wool. In his evidence, Mr. Apperton stated that upon arriving at the house in Valentia Road, he saw the prisoner in one of the rooms. He asked for Mr. Andrews, and the prisoner then said Mr. Andrews had been there, but had just left. The accused added that he would go and see whether Mr. Andrews had left the money. He returned and said Mr. Andrews had left £5 for the silver nitrate, and he would pay the 1s. 6d. for the cotton wool and would sign the invoice as having received the silver nitrate in good condition. The prisoner went on to say that if he (Mr. Apperton) presented the account at a house in Canterbury Road, Brixton, he would receive the money. The silver nitrate was left on the table in the prisoner's room, and the prisoner went with him to the corner of Canterbury Road, and pointed out a house as being the one at which he was to call. He went to that house, but finding that it did not bear the number stated by the prisoner, he immediately returned to the house in Valentia Road, and found that the prisoner was not there, and that the silver nitrate had gone. At night he saw the prisoner in the Brixton Road, and gave him into custody. The landlord of the house at Valentia Road stated that the prisoner had engaged a room on Friday morning.—Bail was refused.

THE STATEMENT OF AFFAIRS OF J. E. L. REES (trading as the Gwalia Photographic Company) of the Drill Hall Yard, Pentre, Glamorgan-shire, photographer, late chemist's assistant, shows net assets figure at £78 12s. 6d., the deficiency being £165 6s. The bankrupt states that between August 14th, 1904, and December last, he earned as a chemist's assistant £40. He accounts for this amount and his deficiency. The bankrupt (age 25 years) has lived in premises at 45, Carne Street, since February last. Before that he lived at No. 75, Llewellyn Street, Pentre, and previously for certain periods in several towns in England and Wales, during which time he was employed as a chemist's assistant.

WOOD, LIMITED.—Registered August 22. Capital £500, in £1 shares. Objects: To acquire the business of chemists and druggists carried on at 31, Hillidge Road, Hunslet, Leeds; by S. R. Mundell, and to carry on the same and the business of herbalists, opticians, druggists' sundriesmen, dealers in photographic apparatus and materials, etc. Registered office, 31, Hillidge Road, Hunslet, Leeds.

"POETRY" is not often enlisted in the photographer's advertisement, but we have been interested in a circular of the sixties, in which an offer of a photograph complete with frame for 1s. is supported by some lines commencing:—
Wonders every age arise,
Excel before our wondering eyes.
Some aerial wonders make us laugh—
But ponder o'er the photograph.

News and Notes.

GLAZED STEREOSCOPIC PHOTOGRAPHS.—The "Photo-Critic" gives the following practical hints:—In the first place, one must decide on the size and shape the stereo is to be, whether the two as a single print made by cutting the negative and reversing, or two single prints mounted as is the custom to-day. If two separate prints have been decided upon, then squeegee plates of the exact size must be used, and pressed down in the usual manner, but care must be taken so that the right and left can be easily detected, so as to make no mistake in mounting. This can be overcome by cutting the outer lower corner a little round, which will come in the centre of the card and remain unnoticed. After the prints are pressed to the plates, which have been polished well with a few drops of benzole, 4 oz., paraffin 10 gr., using a large wad of cotton, they are allowed to rest a moment, when paste is applied as usual, but just enough to stick. Both prints are now mounted on the card, and placed under a weight for at least five minutes, when the print is placed away to dry in a cool place. (Glazed prints should never be allowed to dry in a warm room, if so they will always curl.) The tins will then fall off when dry, and the result will be a clean job, bringing out in the stereoscope those delicate lines that we all so wish to see. This late method of glazed stereographs has come to stay because of the fine finish that does away with that so-called matt surface which is so common in the old style. Of course, glazed stereos made on a large scale are mounted in forms fixed to a table so as to do the mounting quickly, but the method described is practically the same.

It is understood that the Sunderland Photographic Association intend holding a big exhibition in the Wearside borough some time during the winter. Photography appears to be in a very flourishing state in Sunderland, says the "Newcastle Chronicle," as may be judged by the fact that there are at least three societies with an aggregate membership of something like 250. For a few years back the Sunderland Camera Club and the Photographic Association have held open exhibitions on alternate years. This is a very good plan, as each Society has endeavoured to emulate the achievements of the other, with the result that Sunderland has been treated to a succession of exhibitions equal to any held in the provinces.

PROPERTY IN PHOTOGRAPHS.—A letter from Mr. William Grove, hon. sec. of the Professional Photographers' Association, appeared in the "Daily Chronicle" of August 24, in reference to the interview with Mr. Clement Shorter, to which we have already referred. Mr. Grove says:—"The attention of the Committee of the Professional Photographers' Association has been directed to an article which appeared in your issue of July 8, wherein Mr. Clement Shorter, in commenting upon a legal case in which he was interested, took the opportunity of reviewing the present system of dealing with photographic copyrights from his own point of view. He has since disclaimed an historical statement attributed to him, and has explained that in applying the term "robbers" to photographers he did so only in a limited sense. Mr. Shorter is notoriously no friend to photographers as a body, whatever he may be to a few individually, and the reason is a natural one—his interests and theirs clash. He, as conductor of certain illustrated papers dependent upon photography, desires to obtain the pictorial matter for his paper at the lowest possible rates. Photographers, as men in business, want to sell their wares at the highest possible rates. This accounts for the warning which Mr. Shorter gives to public characters not to allow photographers to acquire the copyright in their portraits. Photographers generally would heartily welcome the change in the

present system that would be involved in everyone acquiring the copyright in his own portrait, for that would mean that everyone who wanted a portrait would have to pay for the sitting. But a small proportion of photographers are able to cater for the Press, for the business is a speculative one. To do so entails giving free sittings, not only to persons who have become celebrated, but to hosts of others who may have a remote chance of doing so, and if there are prizes there are also a great many blanks."

GENERAL BOOTH and the Camera.—Our comments in last week's JOURNAL on the irrepressibility of a certain class of photographers are well exemplified in an account of General Booth's visit to Stockton as supplied by a special correspondent to the "Daily Telegraph." He says:—"The farther General Booth travels the more numerous become the camera fiends who lie in wait for him at every turn and corner. Sometimes they climb lamp-posts and trees, and sometimes they scorch after him on cycles, and take a snapshot at random. One man, perhaps a little more audacious than the rest, having erected his tripod, got two small boys to hold a string of flags right across the road, and thus compelled the car to pull up. On Monday morning the General appeared at South Shields market-place a quarter of an hour before the time for starting in order to say good-bye to the people. No sooner had he begun his address than a photographer, aided by a group of assistants, wormed his way through the crowd, and, within a few yards of the car, put up an elaborate tripod, some 9 or 10 ft. high, with a step-ladder. From this position he took portrait after portrait while the General was speaking. The veteran stood it for some time, and then burst out: 'In spite of the weather, so unfavourable for motoring, I enjoy myself. I have a religion that is not affected by weather. There is only one thing that does annoy me, and that is when I want to speak to people's hearts a photographer comes and sticks up his camera just before me. The photographers have never done with me. They ask for "one moment," and you give them a quarter of an hour, and then they have not done.' (To the photographer): 'Hurry up, please, and when you have finished, pull your concern down. What right have you to spoil my last few minutes with these people? In all probability, I shall never see them again.' Notwithstanding the protest, the man remained where he was until the crowd insisted that he should go away."

BURGLARY at the City Sale and Exchange.—The large sheet of plate glass of the photographic window of the Fleet Street branch of this well-known house was early on Sunday morning last (26th) smashed by some person or persons at present unknown, the object being apparently burglary. Owing to the promptness of the police, who, without doubt, disturbed the thieves before they had time to complete the transaction, the large stock of valuable cameras on show was left undisturbed. Several pairs of valuable opera and field glasses were, however, taken. That they left hurriedly is proved by the fact that they left behind them the heavy iron jemmy with which the window was broken. The police have the matter in hand.

DEATH of a FRENCH ARTIST.—The death of M. Bouguereau, in his seventy-ninth year (says the "Globe") will be almost as much regretted in this country as in France, for his pictures have always been much sought after by British collectors. He was probably the best exponent of the academic tradition who has been seen in our time, the most severely accurate in draughtsmanship and the most precise in methods of handling; and in the long series of pictures which he painted during the fifty-six years of his working life he never showed any inclination to modify his manner. That he ever attained to any great heights of imagination in his art can hardly be said, but he deserves to be remembered as an accomplished and learned craftsman and as a master of technical practice.

THE ACTION OF METOL AND ORTOL ON THE SKIN

To the Editors.

Gentlemen,—Your correspondent, Mr. A. R. F. Evershed, is quite correct in stating that adurol has the same effect as metol on some skins. It has on mine. The last time I used metol was about eighteen months ago. Owing to its irritating nature on my skin, discontinued its use, and did use adurol as a substitute. However, I found that this latter has acted in exactly the same way. Consequently, I had to give it up as well.

Since about a year I have been using Lumière's dianol (which, I understand, is amidol). This latter has acted on my skin in the same manner as metol and adurol did, and I have now both my hands covered with cuts and blisters, and quite incapacitated from doing anything. This dianol has acted on the skin of an assistant I had as well. The worst of it is that it not only attacks the fingers, but that now is spreading up my arms, and shall be grateful if anyone could mention an efficacious remedy. A doctor has given me some oleum deoline for a cure, but since I have been using it my hands are getting like burst fried sausages.—Yours truly,

J. MALLIA.

285, Oxford Street (Oxford Circus), London, W., August 28, 1905.

To the Editors.

Gentlemen,—Metol, even in small quantities, or if mixed with other developing agents, always causes me irritation for five to nine days, and the skin peels off. This is especially noticed on the third and fourth fingers of the left hand, but it is only round the fingernails that the trouble ensues. Respecting ortol, I have used many pounds' worth, and except a yellow-brown stain, have had no inconvenience. Using large plates and larger paper, up to 30 by 20, the hands necessarily are immersed in quite a reasonable quantity of solution.

ARCHER CLARKE.

20, Larkhall Rise, S.W., August 25, 1905.

To the Editors.

Gentlemen,—I see complaints are still made of the ill-effects of metol on the fingers of some who would like to use it, presumably, on account of the early appearance of the image, and the small amount of alkali needed. If hydroquinone is used alone, or eikonogen, strong alkali is required, or development is slow, and strong alkali is bad for fingers and films. But to secure the accelerating effect of metol, a very small quantity only is necessary when used with other developers, and then no ill-effects need be feared. Four grains of metol are quite enough for forty ounces of developer, and my favourite mixture at present is:—4 grains metol, 40 grains eikonogen, 20 grains hydroquinone, 4 grains potass. bromide, dissolved in 20 oz. water to which $\frac{1}{2}$ oz. soda sulphite and 10 drops sulphuric acid have been added. No. 2 solution is simply soda carbonate crystals 1 oz., water 20 oz., and equal parts are used. This allows of short exposures, secures early appearance of the image, and produces ample density in four to five minutes, and, with good plates, will not cause fog.—Yours truly,

E. WILLIAMS.

Highgate, Hawkhurst, August 26, 1905.

THE ACETYLENE LIGHT.

To the Editors.

Gentlemen,—In reply to the letter re "acetylene gas" from Mr. E. E. Organ, in the current issue of the B.J.P., the following notes may be interesting:—

About eighteen months ago we received an order to attend at a private fancy dress ball and open a studio during the night.

There was no means of having either gas or electric light laid on, the house was situated about two miles from the nearest town.

We therefore had to resort to acetylene, which could be generated on the spot. Numerous trials were made with five, ten, and fifteen burners, but all unsatisfactory. As we only had two days' notice, our apparatus was somewhat crude, there being no time to get properly-made apparatus.

After the numerous trials we decided upon and got a local iron-rounder, etc., to make us the following apparatus:—

One ordinary circular splash bath was fixed upon a stout bar of iron and made to raise or lower by a clamp at the back. Then a piece of tin was fastened round the rim of the bath, so making it

deeper, as it were, and also concentrating the light more upon the subject. Then acetylene burners were placed in the bath in rows as follows:—Top row, four; second row, ten; third row, ten; fourth row, five, and these were made to turn up or down altogether by a screw at the side. There was also one burner in the centre on a separate tap, by which to focus.

The whole of the apparatus was enamelled white. The gas was generated upon a lawn about twenty yards from the room, and carried up through the window in an ordinary garden hose pipe.

By the use of a large mirror as a reflector to lessen the shadows, excellent exposures were secured at five seconds, using a Barnet extra rapid plate and a Voigtlander's euryscope (portrait) lens, worked at $f/22$.

Trusting these notes will be of use to your querist, I am, gentlemen, yours faithfully,

H. ESSENHUGH CORKE.

39, London Road, Sevenoaks, August 25, 1905.

Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- J. P. Blair, 19, L'Avant Street, Petersfield, Hants. Photograph of an Explosion by Royal Engineers at Longmoor Camp.
- A. Simmons, 258, Westminster Bridge Road, S.E. Photograph of a Group of Members of the Terriers' Association. Photograph of an Illuminated Address.
- M. H. E. Currie, 16A, Brunswick Street, Teignmouth. Five Photographs of Teignmouth Lifeboat Day, 1905. Photograph of the Teignmouth Water Polo Team, 1905.
- E. Cooper, 69, Duke Street, Southport, Lancashire. Photograph of the Southport Corporation Band, 1905.
- S. H. Greenway, 27, Abington Street, Northampton. Photograph, Group of Australians and Northants. Cricket Team (County Championship).
- J. McPherson, 63, Gellatly Street, Dundee. Photograph of Part of the Tay Bridge after it fell into the River Tay.
- W. Fletcher, Port St. Mary, Isle of Man. Photograph of Chicken Rock Lighthouse, Port St. Mary, Isle of Man.

G. E. S. (Dublin).—If you will look in the "Almanac" you will find announcements of dark slides of the kind you require. Practically all of them can be fitted to any camera.

WAGES ABROAD.—Would you do me the favour of publishing in your next issue of B.J.P. the wages a good class printer earns in South Africa or Canada?—S. B. A.

We can only name figures in isolated cases, which would not assist our correspondent. Perhaps some Canadian or South African readers will let us hear from them.

PERIODICALS.—It would oblige me very much if you would answer the following questions in your valuable column:—Where can I obtain the paper called "Kokka" from in England, as mentioned in last week's B.J., also the value of two yen? Could you also tell me of a few American photographic papers and prices of same, and where obtained? Can they be obtained from Smith and Sons, the railway newsagents?—J. R. BOARD.

If you will look at the paragraph again you will see that the paper can be obtained from Mr. Quarritch, 15, Piccadilly, W. You will find a list of the American photographic papers in the "Almanac." They cannot be obtained in this country except on order. Messrs. Dawbarn and Ward, 6, Farringdon Avenue, London, E.C., can get any of them for you.

F. B. (Scarborough).—It is against our rule. We must leave you to guess.

J. MALLIA.—We acknowledge your suggestion, but we fear it is not practicable.

ALBUMEN.—I should like to ask your advice in selecting albumen from three samples sent (if they are good ones) No. 1, No. 202, and 282. I find a difficulty in getting it clear, strong, and easy to melt. I mean getting it as good as is possible. They send me different stuff each time. I have it from a large firm, but they do not make it. It costs 2s. 10d. or 3s. per lb. in 10 or 15 lb. lots. Do you know of any firm where I could always

get the best possible without trouble? I find the orders do not always come as good as the samples. Would it be difficult for me to desiccate it myself? Have the samples any other substance mixed with them—if so, what?—TREDEGAR.

We have compared them with samples which we know to be good, and can see no difference. You can dry your own albumen by exposing the white of egg in shallow vessels to a temperature not exceeding 120 degrees Fahr.

PHOSPHATE BATH.—A short time ago you were kind enough to give me a hint with regard to getting cold sepia tones with platinum on collodion paper, and recommended the phosphate bath diluted. Would you kindly let me know what you consider the best formula for this bath?—EXPERIMENTALIST.

Potassium chloroplatinate, 2 gr.; phosphoric acid (sp. gr., 1.12), 3 drachms (fl.); water, 10 to 20 ounces.

GOLD MEDAL FOR RETOUCHING.—I shall be greatly obliged if you can give me a little information upon the means negative retouchers have to take to obtain a gold medal for their work. Also, if it is necessary for them to have a practical knowledge of photography before they can obtain it.—QUERY.

No gold medal is awarded for retouching alone, so far as we are aware. The City and Guilds of London Institute grant a gold medal annually for general photography. You will obtain particulars from the Secretary, Exhibition Road, London, S.W.

RETOUCHING (reply to Max).—Your touch is excellent for brightness, delicacy, and solidity, and many firms would hail you as a very fine retoucher; but if you value your own artistic well-being, at once discard the excessive flattery you indulge in, and treat your subjects more naturally. "A" is beautifully worked, as far as mere work is concerned, but the character is rejuvenated away, and he might pose as a testimonial to a skin soap or lotion. "B" is in the same category, and we prefer the unretouched for truthfulness and effect. "C" is very nice, but you should have knifed or pencilled the neck to better form—it is ragged. With more attention to the likeness and character, and greater variety of touch to suit the subject, you will make a really first class retoucher, worthy of the highest firms.

IODINE HYPO ELIMINATOR.—Some years ago I came across a method of eliminating hypo with an iodide salt. Can you give me the formula, or refer to a back volume of the JOURNAL in which it appears? I want to prepare some prints very quickly.—E. H. MAX.

Probably our correspondent refers to an iodine salt suggested by Mercier in 1898, the formula for which was: Iodine, three parts; salt, thirty parts; sodium carbonate, thirty parts. Mix well, and dissolve in 1,000 parts of water, and allow to stand, or heat, till colourless. The action of this is extremely doubtful, and it was pointed out by Bolton (B.J., Vol. 44, p. 520) that if any silver thiosulphate remains in the film, it will be precipitated as iodide. Further, that this salt had a considerable reducing action. It would be far better to use one of the commercial preparations, if necessary, which are mostly persalts, and have not such doubtful tendencies.

CARBON SUBSTRATUM.—Can you tell if it is possible to use any alcoholic or semi-alcoholic substratum for carbon prints? What I want is one that will dry rapidly and will not penetrate the surface of material much.—PROGRESS.

Possibly the following might answer the requirements of our querist: Dissolve $\frac{1}{4}$ oz. of Nelson's soft gelatine in 1 oz. of

glacial acetic acid by the aid of heat; also $\frac{1}{4}$ oz. of chrom alum in 1 oz. of water. For use, mix methylated spirit (non-mineralised) 50 drachms, water 20 drachms, and add gradually with constant shaking, and if any gelatine is thrown gently heat, gelatine solution $2\frac{1}{2}$ drachms, and then chrome alum solution 1 drachm. This can be flowed or painted over the surface; it has not much tendency to penetrate, and dries in about an hour.

J. W. H. B., H. S., and Others.—In our next.

COLOUR-PHOTOGRAPHY.—The week before last there was a notice about a studio being opened in Berlin for photographs in colours. I know nothing about it, but want to go in for it professionally. Can you give me names of books, etc., on it and place to buy colour filters, etc., so that I may begin to experiment in it?—NATURAL COLOUR.

Messrs. Marion publish an excellent work on colour-photography by Bolas, Senior, and Tallent, and you may get also Hübl's "Three-colour Photography," published by Penrose and Co. For particulars of a process now on the market, write the Rotary Photographic Company, Limited.

F. C. S.—Collodion dry plates have not proved a success on the market, and there are several good collodion emulsions. We cannot see that there is an opening for pellicle.

LIGHT FOR RETOUCHING.—Would you please tell me the best light, etc., for retouching after dark, as I have no time in the day for practice? I cannot have gas or electric light, as this town does not possess either.—P. W. WEBB.

Your only course appears to be to use a good oil lamp. Diffused daylight is, of course, the best light for retouching, and then electric light, but as you cannot employ these or gaslight, a paraffin lamp with argand burner and a reflector will be the best for your purpose if you have a reliable retouching desk, with either a mirror and ground glass, or with clear glass and white opal reflector.

DEVELOPING P.O.P.—I shall be glad if you can give me a formula for a developer for partial-printed P.O.P. postcard that will not stain the unsensitised side of the postcard. Will any of those you gave a fortnight ago do? I have been using the Kodak formula for the past two years for prints, but it will not do for postcards, as it stains the back of them.—WILLIAM FOX.

An acid developer such as those given in our issue of August 18 is much more likely to discolour the backs of the cards than the bromising process of development brought out by the Paget Prize-Plate Company, and described in a booklet issued by them. You had better obtain it.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Hon. Secs. Please Note.

We are sending this month to the hon. secretaries of all photographic societies in the United Kingdom and abroad our annual request to furnish us with the latest particulars concerning their societies for free insertion in the "British Journal Almanac." This list of societies and information concerning them has always been a feature of the annual, and its utility for reference cannot be questioned. We shall be obliged therefore if our friends the secretaries will kindly fill up the forms sent them and return to us at their earliest convenience. The inclusion of reliable data of this description in a publication with the world-wide publicity of the "British Journal Almanac" is a point that should not be overlooked by the executive of any society that desires to keep its name alive in the photographic world. We shall be pleased also if all lists of fixtures and dates of forthcoming events are sent to us as soon as ready. They will then be published week by week in the column devoted to meetings of societies.

* * *

The Solar Eclipse.

A cloudy day in London on Wednesday of last week obscured almost completely every sign of the partial eclipse of the sun. Other parts of England were, however, better favoured, but even visitors to the north of Spain, the nearest accessible spot for the observation of the phenomenon, had the sensation of standing beside their cameras in doubt as to whether passing clouds would make their journey fruitless. But on the whole the weather appears to have been kind to the astronomers and photographers, and to have done its best on an occasion which will not present itself again, within such easy reach of London, for another seven years. In 1912 Spain will again be the rendezvous, and in 1927 a total eclipse will be visible in England for the first time for four centuries.

* * *

Eclipse

In another column we publish an account of the practical experiences of a photographer who journeyed to Burgos for the purpose of securing negatives of the eclipse, and who was favoured with the success that was unfortunately denied to several of the expeditions that travelled long distances to reach specific points along the line of totality. This was particularly the case with the parties with Sir Norman Lockyer at Palma, Majorca, and with Professor H. L. Callendar, at Castellon. The Canadian observation party at Labrador was also unsuccessful, owing to the cloudy weather, but most of the other observations were carried out under satisfactory conditions. Perhaps the most interesting series of photographs so far as the circumstances surrounding their taking are concerned were those

B

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

PRELIMINARY ANNOUNCEMENT.

The forty-fifth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,612 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1906 will also consist of 25,000 copies.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1906 will be modified to make it more than ever the book of universal photographic reference. As in the past, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1906 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded, and wherever practicable new features of an informative nature will be added.

*** IMPORTANT NOTICE.—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1st, so as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

secured by Mr. F. H. Butler and Mr. Percival Spencer from a balloon at a height of 7,000 feet above the earth. The experiences of these aeronauts, who covered a distance of 200 miles, and made a record voyage across the Channel, are probably unique among the many photographic enterprises connected with the eclipse.

For Photographic Societies.

In the present issue commences a series of articles dealing with the position of photographic societies and exhibitions in this country, with notes on their management. These articles have been written for us by a gentleman who has had long practical experience in society and exhibition management, and his suggestions for the improvement of both should be carefully studied by the secretaries of every photographic society in the Kingdom. We would, therefore, particularly draw their attention to p. 707, containing the introduction to these articles, and feel sure that every society will profit by the adoption of one or the other of the hints given by our contributor. There is no doubt that the photographic society of to-day is a very different affair from what it was twenty or thirty years ago, and the circumstances that tended towards the success of these organisations in the past are in many cases almost entirely absent now. It therefore behoves the officials of our present societies to look to the means of making their institutions popular and useful by other means than those that obtained in the past.

The Exhibition Season.

With the opening of the two big London shows—the R.P.S. and the Salon—the exhibition season may be said to have fairly started. A glance at the list of forthcoming exhibitions on p. 712 should tend to convince the most sceptical that there is no lack of interest taken in these annual functions, and the reports of exhibitions held during the season that is past show that there has been no falling off in the support given them, but rather that the tendency among amateurs to exhibit their work is on the increase. Whether this is an unmixed blessing is beside the point under consideration. We are more concerned with the fact that the competitive spirit and the spread of photography show no evidences of abatement, and we regard the sign as a healthy one. In many instances the annual exhibition serves the double purpose of not only quickening the interest of members of societies in their work and giving them and the public a better idea of the progress of modern photography, but also the finances of the society are usually assisted to some degree. This point cannot be overlooked when making arrangements for the event, but unfortunately however, one fault appears to recur with distressing regularity year after year. We refer to the clashing of exhibition dates. Last spring we discussed this matter at length (see *BRITISH JOURNAL* for Feb. 10, p. 103), and suggested a means whereby the overlapping of dates could be avoided. To a certain extent this advice has been followed in the present season, but still there are cases where the same date has been chosen for the opening of two or more shows. It is obvious that each will be considerably weakened by the presence of the others, whereas if they had been fixed to follow one another the probability is that each would receive the full complement of entries that will now be divided. We therefore take this opportunity of again drawing the attention of secretaries of societies to our list of forthcoming events, and if the dates of their annual exhibitions have not been decided upon, to choose one that will not clash with any that are already fixed, or at all events enter into some arrangement with the society whose date they wish to

follow, to forward the pictures direct from one show to the other. This list of fixtures will be brought up to date and published at frequent intervals throughout the exhibition season.

Greenwich Royal Observatory.

A certain amount of perturbation has been aroused by an article appearing in the "Daily Mail" suggesting that the research work of the Royal Observatory might be carried out at some point on the meridian of Greenwich, where the atmospheric conditions are much more suitable than those that normally prevail in Greenwich Park. Professor R. A. Gregory, professor of astronomy at Queen College London, on being interviewed on the matter said:—"Greenwich Observatory was originally intended for the use of scientists to measure the stars year by year; the data acquired being used in the compilation of nautical almanacs, etc. For that purpose it is still quite suited, but there is in my mind no doubt that the spectroscopic and photographic research, which is now such an important feature of the work of the Royal Observatory, would, carried on in a clearer atmosphere, yield better results than at present. The question is one of money." There appears, however, to be no real necessity for moving the observatory, as the observations that they are able to make at Greenwich compare favourably with those of other countries, America, perhaps, excepted.

Photography in the Streets.

The roads are up. London at the present time is chaotic, so far as vehicular traffic is concerned in most of the main thoroughfares, and despair is written on the face of the man who charts a cab for the purpose of getting quickly from one point to another. This is doubtless being repeated in various provincial towns all over the Kingdom, and bad though it may be for many people it may occur to the photographer with a hand camera and an hour to spare that here at hand is some of the most striking and picturesque material for snapshots he could desire. The pictorial attributes of the British navy and work are remarkable. He groups well with his fellow navvies, and his movements are graceful. A focal-plane shutter is not a necessity for the purpose unless the dinner hour is indicated, while the roads wherein he toils are usually sufficiently blocked to render any special precautions on the part of the photographer needless. The light is still good enough during the greater portion of the day to secure perfectly exposed negatives in the streets and it is only necessary to make a preliminary tour of inspection one day for selecting the best settings for the men at work, and come again the following day with the camera. They will still be in about the same place and the exposure can be then made without undue haste. The value of these typically modern street scenes, apart from their pictorial interest, is such that they should find a place in the record department so strenuously advocated by Sir Benjamin Stone.

Collodio-Albumen.

In "The Week in History," on another page, our contributor, "Historicus," describes the process of M. Taupenot in practically the words of its inventor. That description, however, scarcely represents the status which the process rapidly reached on its introduction. It was not long before the sensitiveness and keeping properties of the plates were greatly enhanced. Although the process has long been obsolete it is within our experience that they could be kept for months after sensitising, and, if they had a wash of dilute gallic acid, for a very much longer time. It was usual to make the sensitising bath much stronger than Taupenot's—forty-

grains per ounce—and after a time gallic acid gave place to pyrogallie as a developer, which made the time of development much shorter. For many years the collodion-
 albumen was the, almost, universal dry plate process. Then after the introduction of the collodio-bromide process of Bolton and Sayce, Taupenot's process continued to be employed by many workers, notwithstanding that the preparation of the plates involved two coatings and two sensitizings.

Casual advertisement

A week or two ago we referred to the report of a semi-public function, involving photography, in which no mention was made of the photographer. This latter, however, for the good reason as we were informed—that the work was done by an amateur. Nevertheless, there are many occasions when such opportunities occur, and are neglected—or embraced. An instance of the latter lies before us in the shape of a paragraph from a good Midland weekly newspaper:—
 "We notice in Mr. F— G—'s window in High Street a first-rate enlargement of the portrait of the late Mr. Isaac A—, which we recently published in our columns. We should like to see a similar enlargement hung in the board room at the E— Union Workhouse. In the board room at the Shipston Workhouse hang portraits of two late chairmen. Perhaps the E— Board of Guardians will . . . hang in their board room the portrait of such an excellent chairman and so valuable a public servant as the late Mr. Isaac A—." A little paragraph such as the above may occur unsought in many places, but chiefly in connection with photographers wide awake to what is passing, and not needing such reminders as this we are now penning. We are afraid that the man who requires rousing to move in such directions are lacking in the advertising instinct and unable to discern any of the occasions when public notice may be drawn to their work.

ARE SILVER RESIDUES WORTH SAVING?

One time, that is in the wet plate days, when a photographer had to deal direct with nitrate of silver, the above query would have been considered quite short of ridiculous. At that period the professional, and a great many amateurs, systematically recovered all their wastes, and when they were collected and afterwards reduced by the refiner they formed a valuable asset. The case is different now. Professionals, except those who sensitise their own paper, have not to do with nitrate of silver, and some present-day amateurs have probably never even seen the article. In the wet collodion process a large quantity of nitrate of silver was consumed in the sensitising and development of the plates, a considerable proportion of it was reduced in the developer, and the muddy sediment that accumulated at the bottom of the tray over which the plates were developed was simply metallic silver. As the paper then used was strongly treated and was sensitised on a very strong solution of the salts—sometimes eighty to a hundred grains to the ounce—the washing waters of the prints, before they were fixed, were rich in silver, and so, also, were the used fixing baths, by reason of the large proportion of silver chloride in the paper. It was estimated by different authorities, some thirty or more years ago, that, under the then conditions of silver printing, not more than from five to ten per cent. of the silver used in their production remained in the finished pictures; hence there was something like ninety per cent. of waste, a large proportion of which was recoverable. It was computed at the time that from fifty to sixty per cent. of the silver purchased could be recovered

without any great expenditure of time or trouble. The late Mr. Geo. Dawson, in an article published in the *BRITISH JOURNAL* in 1881 (vol. XXVIII., p. 439), says that he had recovered as much as seventy-five per cent. of the silver used in printing, and that with only ordinary care and little trouble. From what has been said it will be seen that in the old days there was no question as to the residues being worth saving. But the large amount of silver recoverable at that period was not all that made the valuable asset. The value of the metal then was very different from what it is now. Referring to the money articles of the "Times" for 1867, a time when strong sensitising baths for paper were employed, and when the collodion process was the only one in vogue—we find that the price for standard silver stood for some time at 60½d. per ounce. One day last week it was quoted at 27½d. the ounce—considerably less than half the price it was forty years ago. Even so late as 1881 we find the price of standard silver quoted at 51½d. an ounce. From this it will be seen that whatever amount of silver may now be recovered from residues it will not realise one-half the sum it did forty years ago.

Let us now look at the conditions prevailing at the present time as regards silver residues. Gelatine plates contain no free nitrate of silver, bromide papers contain none, and the commercial "P.O.P.s" but little as compared with the old albumen papers. Hence the greater portion of the silver now recoverable must be sought for in the fixing solutions. The proportion that is recoverable from the washing waters of P.O.P.s is small, as these papers contain but little free nitrate, its function, to a great extent, being taken by organic salts of silver, which are practically insoluble in water.

Let us now look at the silver in gelatine plates. Investigations made by Messrs. Haddon and Grundy some time back, with commercial gelatine dry plates, showed that some contained less than one grain of silver to the quarter-plate, and these were amongst the most popular ones. Others contained more, but not to any great extent. Now, if we take as an average, say, fifteen grains to the dozen quarter-plates, we shall see that a gross of plates contains but 180 grains of silver to begin with. A good proportion of this is reduced, in development, to form the images, and that quantity naturally depends upon the subjects photographed. For example, if it be a sitter in a light dress, and taken with a tolerably light background more silver will be reduced in the film than in the case of a landscape in which but little sky is included, so that it is difficult to strike an average. But if we take it that, say, half the silver is reduced there is then but 90 grains to be looked for in the fixing solution from a gross of quarter-plates. Bromide papers, or papers for development, contain less silver than plates, and consequently there is still less to be got from the fixing baths.

Collodio-chloride papers contain free nitrate of silver that may be recovered from the washing waters, but the quantity is very small as compared with that from the albumen paper of the olden days. With regard to the ready sensitised albumen paper of the present time, that also contains less free nitrate, and less chloride of silver than does the generality of that of home sensitising, but yet still larger than the general run of P.O.P.s. Of course, there are also residues that are recoverable in the shape of cuttings from untuned, and also from spoilt prints. These, when burnt, add something to the value of the other residues.

From what has been said, the reader, particularly he who works on a limited scale, will be able to form an idea as to whether the residues to be recovered at the present time are worth his consideration, and whether, when they

are recovered, they will repay the time and trouble expended upon them, little though it be. This is a query that has frequently been put to us.

Before coming to a conclusion on the point, the cost of the sulphide of potassium (liver of sulphur) required for the precipitation of the silver from the fixing baths and the refiner's charges for the reduction of the residues to the metallic state must be taken into consideration. Also, and not least, the small price the metallic silver realises when recovered.

PRINTING PROCESSES.—XII.

BROMIDE PAPER.

THE great number of excellent brands of paper now on the market makes any remarks on the preparation of bromide paper less important than in the case of plain salted and albumenised papers. Bromide paper is produced commercially more evenly and better coated and cheaper than could be prepared at home on a small scale, and although the emulsions employed by various makers undoubtedly differ in detail, the difference is so slight that all makes can be said to give practically the same comparative results. Degrees of rapidity, variety in surface and thickness are, of course, peculiar to certain bromide papers, but speaking generally the processes of exposure, development, and after treatment are the same for all.

For the professional photographer bromide paper has particular claims for recognition outside of its extensive use for picture postcards. It is a fact, however, that contact bromide prints are not produced by the average professional photographer to anything like the extent that the facility, beauty, and comparative permanence of the process would indicate.

Every photographer utilises bromide paper occasionally, usually in cases of urgency, when it is desired to produce proofs rapidly, and unless they are for the purpose of reproduction in the illustrated press, full justice is seldom done either to this method of producing prints, nor is the most made of the negative because of the photographer's necessarily intermittent acquaintance with the procedure. Second-rate work is the result, and bromide paper does not therefore usually rank high in professionals' estimation except for the purpose of enlargements, when the circumstances are different. Amateurs, however, have not been slow to seize upon the advantages offered by a process at once simple and capable of endless modifications, and the large proportion of pictorial work in this medium at the annual exhibitions amply testifies to its extensive employment by them. In view of the fact that there is always a greater uniformity between the negatives of the professional photographer than between those of the amateur, the extensive and careful use of bromide papers ought certainly to receive more attention.

The paper is purchasable with surfaces varying from the most glossy to that of rough drawing paper, and a range of colours rivalled only by carbon is obtainable at will. In addition it can be worked entirely by artificial light, which is a great point in its favour, for the consideration of the busy worker during the short days of winter, when daylight printing is considerably curtailed. The so-called "gaslight" papers allow of even greater ease of working inasmuch as their manipulation can be carried out in the light of an ordinary room. They will be treated of later.

The best light for the development of bromide papers is that given by gas, oil or incandescent electric light

filtered through one thickness of canary fabric. If daylight is the illuminant it should first be shielded with yellow glass, and then further covered with canary fabric. It is astonishing, however, the amount of bright yellow light that can be used with ordinary bromide paper without risk of fogging. Nevertheless to satisfy the worker and to avoid the possibility of any future trouble it is always as well to test the light by placing a piece of the paper in use in a developing dish with some normal developer, covering half of it with a piece of card allowing it to stand in the direct rays of the yellow light for ten minutes or so. If the light is not safe, the half of the paper that remained uncovered will be found to be perceptibly developed.

Now although any bromide paper will, in capable hands, give a perfectly satisfactory print from any type of good negative, there is no doubt that it is as well to suit the speed of the paper to the character of the negative. That is to say, for negatives that are very harsh in contrast, and lacking in half-tones, a rapid paper will give the most harmonious results. For a negative that is thin and flat a paper that is considerably slower will give the best print. Tissue paper or pale yellow glass in front of the negative will also cause a marked difference in the rendering of the latter class of negative, but the greatest amount of control in compensating faulty density in the plate can be achieved by the regulation of the distance at which the printing frame containing the negative is held during exposure.

This is the one point in bromide paper technique where practice does not quite agree with theory. It is laid down as a rule in most of the text books that "the intensity of illumination varies as the square of the distance from the source of light," which means that at twice the distance from the source of light the exposure is not twice, but twice two, that is, the square of two, so that at three times the distance the exposure will be nine times, and at three times three, that is the square of three, and so on. In practical work, however, it will soon be discovered that a negative that requires, say, thirty seconds exposure at one foot from the source of light to give a fully exposed print will require more than sixteen times thirty seconds, that is, eight minutes, at four feet distance, although according to this law of inverse squares the results ought to be identical. This will be found to be the case particularly with negatives that have been developed with pyro and have a pronounced yellow stain. Such negatives will require an exposure altogether out of proportion to their apparent density.

It will be found also that the scale of gradation is shortened when exposing thin or flat negatives at a considerable distance from the source of light, that is, much pluckier prints will be obtained, and that softer prints are produced from harsh negatives by exposing close to the light. Both these facts can be made of considerable value when dealing with negatives that will not give a good print on P.O.P. The negative that gives a good straightforward print on P.O.P. is usually described as an "average negative" in the makers' instructions, enclosed with bromide paper. The density of this "average negative" should be such that if laid flat on some printed matter in bold type, such as the front cover of the *BRITISH JOURNAL*, the type can just be seen through the densest parts.

Control can also be exercised in the production of the print by employing different illuminants for exposing. A lamp or gas flame turned low will prove of great advantage in the case of thin negatives, while daylight may sometimes be used with advantage with extremely dense negatives, especially if they have also a strong yellow stain.

n fact in the case of the latter it is almost a necessity to use either daylight or magnesium ribbon.

It should be borne in mind, however, that with large negatives uneven illumination will result if the printing frame is held too close to the source of light, the middle part of the picture or the part that is held opposite the light will receive more illumination than the corners. With a No. 5 Bray burner or incandescent electric light, a quarter-plate negative ought never to be held closer to the light than one foot. For a half-plate, two feet, and anything over; whole plate ought never to be closer than three feet. The application of the advice on equivalent exposures at varying distances from the light will be more thoroughly appreciated when it is required to give identical exposures to, say, a quarter-plate and a whole plate negative of equal density when the correct exposure for the quarter-plate at one foot from the light is known.

It is advisable in bromide printing, if the most uniform results are required, to keep the variable factors as few as possible. As we have seen, thin negatives can be compensated for by using slower paper, by holding the negative further from the light when printing, by turning the light down and by covering the plate with yellow glass or tissue paper. All of these methods are efficacious, and can be employed on occasion, but it will be found that the percentage of good results will be higher if only one is used and that thoroughly understood. The same thing applies to the treatment of over-dense negatives.

A difficulty is frequently found in making satisfactory vignettes on bromide paper. This is usually due to the fact that the vignetting mask has been used too close to the negative and that the light has not been sufficiently

diffused before reaching the paper. The ordinary method employed for obtaining vignettes on P.O.P., platinotype, or carbon paper will not do with a process where the print is held so close to the source of light as with bromide. The result is certainly a vignette, but the line of demarcation is too abrupt. To produce properly graduated vignettes the mask should be placed at least an inch from the face of the negative and the opening in the mask made considerably smaller than with daylight vignetting. A piece of ground glass (ground side outwards) should be placed in the printing frame before the negative is put in position. Over the front of the frame a sheet of thin tissue paper is fixed. This is separated from the ground glass by the thickness of the rebate of the frame. At a distance of an inch from this tissue paper is placed the mask, which may be a piece of cardboard larger than the front of the frame. By cutting V pieces out of the corners it can be bent down all round, and pinned to the sides of the frame so that the aperture in the mask is kept at least an inch above the piece of tissue paper. This aperture, as mentioned before, should be quite small, although indicating roughly the shape it is desired to vignette, and it may also have serrated edges. With this vignetter the frame should never be closer to the light than three feet. The further off it is the softer will the vignette be, and the longer the exposure. In the case of very weak negatives or with a dense negative that is being exposed to daylight or magnesium light, another piece of tissue paper may be placed over the mask with advantage. In any case the exposure will be considerably increased, and this should be ascertained by means of a test piece of paper.

PHOTOGRAPHING THE ECLIPSE.

THE eclipse of the sun, which took place last week, attracted considerable attention from both the scientific and the unscientific world. In England, which is rarely favoured with a total eclipse, a very considerable portion (about three-quarters) of the sun was obscured. The weather, however, was very unfavourable for observation.

The most easily accessible place in the line of totality for English observers was in the northern part of Spain. Spain seems to be fortunately placed for total eclipses, the eclipse of 1900 being visible there, and another will be seen in that country seven years hence. The town of Burgos being practically in the centre of the path of totality and lying on the track of the Paris-Madrid expresses, was the most favoured spot for the majority of European observers, and was the rendezvous of several astronomical expeditions. The interest in the eclipse was by no means confined to astronomers. A vast number of sightseers and tourists travelled there to witness the interesting spectacle. The fact that the eclipse occurred during the holiday season considerably augmented the number of spectators in the town.

Those who availed themselves of the opportunity to visit Burgos and obtain photographic records of the eclipse were fortunate, as a practically uninterrupted view during the period of totality was secured. There will be no further opportunity of observing another solar eclipse at anything like a convenient distance from England until the previously-mentioned occasion (1912) in Spain. In the meantime, observers will have to journey to Australia, Central Asia, Greenland, and other equally distant regions.

It was this important feature of accessibility in the recent eclipse that led me to visit Spain for the purpose of photo-

graphy. There was another almost equally important feature of the event, the period of totality was unusually prolonged—more than three and a-half minutes—while in 1912 the sun will be observable for only a single minute. For photographic purposes, the extra two and a-half minutes would make all the difference to the convenience of the operator.

Practical Considerations.

To produce a direct photograph of the sun (or, rather, moon) of anything approaching a fair size is by no means an easy task, the diameter of the sun on the photographic plate being about 1-100 of the focal length of the lens. Consequently, a lens of 36 in. focus gives an image of about 1-3 in. Under these circumstances recourse must be had to a telephoto attachment on the lens, stopped down to ensure a sharp image, which will bear an enlargement of several diameters. As there is no necessity for rapid exposures, the lens can be stopped down to *f*64, and the photograph can then be enlarged to any reasonable size. The lenses I used were two of 48 and 36 in. focus respectively, and a small lens of about 14 in. focus, with a telephoto attachment, magnifying four diameters. The cameras were 12 by 10, 10 by 8, and whole plate, weighing over 1 cwt., and they proved a decidedly inconvenient quantity of luggage. The Spanish authorities had made every provision for the convenience of observers and their instruments, and on production of vouchers, photographic apparatus was passed through customs and booking-offices without inspection, or railway charges—an arrangement which assisted very materially in saving time and money.

Our party of three arrived in Burgos only on the evening preceding the eclipse. We had decided to drive out into the

country with our cameras for the eclipse, but every vehicle had been chartered for the following day. Under these circumstances, we hired porters to convey the apparatus to a field near the station. As it happened, this was the best

Fig. 1.—The corona during total eclipse.

method to adopt, for a very convenient spot was found, well protected by a low hill from the rather high wind that prevailed on that day, and we wasted no time in returning to the station after the eclipse.

The operation of fixing up the cameras was rather prolonged, and although we began work at 8 o'clock the three instruments were not in position before midday. The necessary focussing had been carried out in London and the position of the lenses carefully marked, a plan which saved a lot of trouble.

The early morning of the eclipse was beautifully fine, but about 9 a.m. a few clouds made their appearance in the sky, and these rapidly increased till the sky was almost overcast. Matters looked very serious indeed about a quarter of an hour before the eclipse. There was a vacant space, however, in the clouds, which, fortunately, passed over the sun at the critical period, and during totality the corona was not obscured by the clouds at all. A few fleecy clouds passed across the moon's surface in the first minute of the eclipse, but they were so light that the view was not affected by them.

Just before totality, while finally arranging one of the large cameras, one of the supports broke, and it was *hors-de-combat* in consequence. Three plates were exposed in each of the two remaining cameras.

Exposures.

The exposure for sun and corona during a midday eclipse is about $\frac{3}{4}$ sec., with the lens stopped down to $f/16$; if the sky and clouds are required on the plate about three times that exposure is necessary. This time is for fast plates. As I used $f/64$, in order to obtain as sharp an image as possible, our exposure varied from 2 to 8 seconds.

THE WARWICK COMPETITION.—The result of the August competition is as follows:—1st Prize, £10, Charles A. Slater, Esq., Biscot Road, Luton, "The Chantry Gate"; donation £5 to the Luton Camera Club. 2nd Prize, £5, A. R. F. Evershed, Esq.,

A reproduction of one of the photographs of the corona reproduced here (fig. 1). The second illustration shows a curious effect. The plate was the last one exposed, and just as the cap was placed on the lens, the first rays of the sun shot out. This gives a mock sun round the point where the rays struck the plate.

The eclipse, from a spectacular point of view, was certainly disappointing. A few streamers made their appearance, but they were of a very indefinite character, and their visible length not more than two lunar diameters. Compared with drawings of previous eclipses which I had inspected, the appearance of the corona and radiations during totality was very much less striking, and even allowing for stretches of imagination of both astronomers and artists, many former eclipses must have been far in advance of this one spectacularly. It remains to be seen if the eclipse has furnished any proof of the existence of the elusive Vulcan or fresh discoveries concerning the corona.

During totality the light was by no means bad, and small print could be read easily; but, nevertheless, the weird gloom and stillness were very impressive.

There was a total absence of any colour visible to the naked eye in the corona; the sky and clouds seemed of a dull blue-grey tone.

After the eclipse the cameras were packed up as speedily as possible and got away from Burgos by the first train; this made a great difference in the time of our home journey, and, in consequence, my photographs were developed and printed in London by 11 o'clock on Friday morning.

Burgos was filled with tourists of various nationalities, and the whole town gave itself up to the eclipse. The King of Spain and most of the Royal family arrived on the previous evening for the event, and added to the gaiety of the city.

Fig. 2.—The sun emerging after totality. Corona photographed during totality.

The local authorities made strenuous efforts to look after the welfare of their numerous visitors, but the large influx of people caused something approaching a famine in the town.

J. I. PIGE, F.R.P.S.

Streatham Hill, London, S.W., "The Old Bridge"; donation, £2 10s. to the South London Photographic Society. Entries for the next competition must reach the Warwick Dry Plate Company, Warwick, not later than September 15 next.

PHOTOGRAPHIC SOCIETIES AND EXHIBITIONS.

SOME NOTES ON THEIR PRESENT POSITION AND MANAGEMENT.

I.

The Modern Society.

the interest in the work of photographic societies waning? ere appears to be a considerable difference of opinion regarding the answer to this query, and possibly the true state of things can be more clearly determined if it is ascertained what that work is or purports to be, and the conditions under which it is carried on. It is proposed in these notes to discuss the extent of the falling-off in this interest, where it exists, and to suggest means for the renewal of activity. Undoubtedly, in many quarters a lack of enthusiasm is apparent, not only among the members personally, but in their support rendered to the society, and perhaps if an investigation of the circumstances and environment of these moribund institutions is made, the reason of their decadence will be manifest.

On the other hand, there are photographic societies to-day which are in a flourishing condition, both as regards utility, finance, and *esprit de corps*. A comparison of the methods adopted by the executive of a society that is successful, and of one that is not, should prove an interesting study for the latter. This, however, is seldom done, and the question might also be asked: "Is the modern photographic society necessary at all?"

A Comparison.

Photographic societies of to-day are on an entirely different footing from similar institutions of a decade or two ago. This fact is often overlooked by the old adherents of long-established clubs, who are wont to deplore the degeneracy of the present societies and their members. They forget that during the time mentioned, and earlier, photography was in a transitional state, and that photographic experimentalists had more material for investigation and discussion, and greater scope for expansion, than during the past few years. Improvements in photographic optics, plates, developers, etc., and research in other directions occupied a prominent place in the minds of most photographers, and in the discussions at every society meeting. The era of the "button-presser" had not commenced and the average of earnest workers was higher. The average is lower to-day, not because there are fewer earnest workers, but because there are more of the other sort. The increase of photographic literature, and the cheapening and simplification of apparatus, materials, and processes, have also had much to do with the societies losing caste as instructional factors, and the one-time acknowledged utility of the photographic society as a forcing-ground for advancement of the art is not so possible to-day. Good and lasting work can, nevertheless, still be accomplished, especially if the fact is kept before the members of a society that the discussions and work done in the societies of the past have borne fruit in the shape of most present-day improvements in photography. In fact, to the amateur workers of the past fifty years can be attributed most of the methods by which the path of the photographer of to-day is made so easy.

A Function of the Modern Society.

In any case, it should be one of the chief functions of the modern photographic society to assist in moulding the promising beginner or dabbler in photography into a more desirable exponent of the art, and to encourage the interchange of new ideas, practical or otherwise, among the more advanced workers. This can be accomplished either by practical demonstrations, if necessary, or by any means by which interest in the work can be legitimately sustained. This, of course, means a certain amount of self-denial and possibly hard work on the part of some officials of the society, but unless this comparative altruism is forthcoming, one of the principal causes of failure is

at once disclosed. The social side must also not be forgotten, but of this more anon.

The Beginner a Useful Member.

So far as the beginner is concerned, photography usually presents itself to him as a means of simple representation. Later, if his interest is encouraged by association with other photographers—and the tendency of the average specimen of mankind is to discuss with some one of a congenial nature the successes and failures attending a hobby common to both—he will probably begin to regard the process either as a vehicle for pictorial expression or as a field for scientific research, and herein lies one of the chief phases of the utility of the modern society. Even if the beginner does not venture to tread the hallowed paths of art, or seek the wonders of the micro-photograph or spectroscope and sensitometer, there is still an outlet for him in the realms of survey and record work if he wishes to do something useful for the advancement of the society and photography generally. In any case, if the society offers sufficient inducement to him to continue his hobby, and by competition fosters his desire to produce satisfactory results, it will be to their mutual advantage and photography may benefit later.

The beginner is considered first because he is—strange as it may appear—the most important member of a society. He represents the "new blood," which may be the very life of some clubs, and his ignorance is frequently the main factor in revitalising them by drawing into discussion the older members, who are thus given an opportunity of fighting their battles over again.

Other Useful Members.

The other types of useful members common to nearly every society are those who may be termed the "advanced beginner" and the "enthusiastic expert." It may be safely stated that, so far as the real activity of the society in the photographic world is concerned, these three types are the only kinds that are of importance. The other members are of use only to the social or financial side of the association.

The proportions, therefore, in which these elements appear in the constitution of a photographic society decide largely the success or failure of the organisation. The type referred to as the "advanced beginner" is undoubtedly the most "live" element in the membership. He is the beginner who has commenced to "take notice." He has grasped the principles of the art and thirsts for practical information. He is in a transition stage and it depends to a large extent on the society itself whether he becomes an enthusiastic expert, with aims and ideals, or degenerates into a mere local-view-monger, a purblind snapshotter of uncomplaining friends, to eventually drift out of photography altogether.

The "enthusiastic expert" is, of course, the fully developed beginner, who has neither drifted out of photography via the way indicated above, nor yet into the narrow channels of specialism. He is still fully alive to the general causes and effect of failures in his processes and is fairly equipped to surmount them. He is the member to whom the beginner naturally turns for advice, and it is from his ranks that the executive of the successful society should be drawn. Fortunate is the society in which this type of member is in the majority.

The Executive.

The executive of every photographic society appears to have been founded on lines established when the calls made on the honorary secretary were not so extensive or important to the

life of the society as they are at the present time. The result is congestion, and a multiplicity of duties which prevent full justice being done to any one of them. A reorganisation of the personnel of the executive would often save a society from

extinction. The officials, and the various types of photographic clubs and their accommodation and programmes, with suggestions for improvements, will therefore be dealt with in the next article.

"HON. SEC."

VIGNETTES AND VIGNETTING.

III.

"Portrait of Mr. F. behind the door and very like though too much forehead and as to a pillar with a marble pavement and balustrades and a mountain I never saw him near it nor not likely in the wine trade excellent man but not at all in that way."

Charles Dickens in "Little Dorrit."

Styles in Portraiture.

I CONFESS myself unable to say whether the above passage was penned in the days before or after photography became popular, and I have no means at hand to ascertain. It is of very little consequence. Photographers picked up the worst faults of painters and exaggerated them to a point of aggravation. The kind of thing still exists, and by an uneducated clientèle is even liked. It may exist for a century or two to come, maybe. Some sort of background you must have. The best of all for a full or three-quarter figure is the loosely hung curtain, but the various lights and shades of its folds renders it one of the most difficult of backgrounds to manipulate. The plain, simple background is best unvignetted, best left plain and simple in the photograph until the errand boy sticks his fingers through the reality, or the photographic printer's devil wipes his fingers on it (the background, not the negative). Such accidents will happen. Or the plain background may be too severe and want shadowing away by the useful vignette. An ornate background is one of the appliances of the best studios, but the better the studio, the less is it allowed to appear. Enter a modern studio, and you will almost invariably find that its furnishing is as plain as the work turned out is good. Good wine needs no bush, and the old-time accessories of the studio find no place now save in the neighbourhood of the lower middle class and the poor. Always excepting the den of the children's photographer. "Den" indeed! But its stuffed animals are less unreal than of yore; its tiger skins did once traverse the jungle, and its plants and flowers come from the hothouse and the nursery—not the ware houses of Cripple Gate. Even so, and yet they get more or less washed away by the vignetter's brush.

The Full-length Vignette.

In vignetting the full or three-quarter length you must bear in mind that you no longer have, or can seldom claim to have, the same plea that you have in the case of the bust, that of gazing at close quarters, when eyes (the sitter's eyes) must be sharpest, features and shoulders well defined, and the rest fading away towards nothingness, as it actually does on the retina of your eye. You see the whole figure, and to see the whole figure presupposes a certain distance between yourself and subject, and with that distance an equalisation of sharpness in the whole figure. Vignette out the background just as much or as little as you please, but the figure itself must not be vignettied one little bit. The background may be distant, blurred, faded away, but anything you take from the figure itself must be definitely cut off, and cut off at a suitable point. If, for example, you cut off the feet and a portion of the skirt of a standing female figure, the portion left below the waist must exceed in length the portion left above the waist. If the lower portion only of a seated figure be cut away, to escape an ungainly nose of the legs or feet, the seat itself, or at least the top portion thereof must be allowed to print. A standing figure, again, must be shown standing on something if the feet are printed in.

There may be exceptions to the rule, but they are rare. Anything more than the mere head and shoulders must have a base, be that base bounded by the line of a mask, straight curved, or the edge left by the blade of the trimming knife. Top and sides you may vignette away into nothingness as you please.

How the Vignette should be shaped.

The base being defined, the rest of your picture assumes roughly the form of a triangle or truncated cone, the apex which is just above the head. The shading off should follow triangle as nearly as possible, broken, perchance, by a parasol for example, balanced across the arm, perhaps by a gun held in a recognised military position if your subject be a man in military uniform. The point most to be impressed on the tyro is that the vignette should never follow the contour of the figure as if it were a shadow, but rather that of a triangular mass shade before which the figure stands in bold relief, its curves contrasting with the straighter shades of the vignetting mask.

The Vignette for Portraits of Obstreperous Infants.

In the case of young children and babies, vignetting should only be resorted to so far as the accessories are concerned. Redundancy of chair-back or of rug is not a desirable thing in the finished proof. Unfortunately, in the matter of babies a most suitable, and altogether good, thing may be secured in the way of facial expression, but marred by the movement of an arm, foot, or a hand. Should such happen, and—which is very seldom—the defect be beyond the pencil and knife of the retoucher, a little judicious vignetting of the offending limb may be admissible. If possible, avoid it. Any vignetting away of the baby's limbs is undesirable, for although babies are gazed upon at close quarters the angle of view is not greater than that taken up by the head and shoulders of an adult.

Vignetted Groups.

With the group, collectively, much the same thing applies as to the single standing figure, but you are allowed no cutting off. In an ordinary group it may be assumed that you have complied with the well-known rules of art and have got a pyramid or series of pyramids. If the group consists of more than two or three persons, the front row will probably be sitting or standing down. You must show their whole persons if possible, but vignette away as much superfluous foreground as you please. Up to whole plate this vignetting is sufficient. Beyond that if you ask me what style I prefer, I must plead guilty to a preference which I have found the general public shares. Vignette dome-shaped and actually interpose a dome-shaped mask (not an oblong with rounded corners, but a dome with square base and well-rounded sweeping arch) between film and sensitised paper. When the print has been sufficiently impressed, remove from frame, and with the "cut-out" of the dome to protect the print, tint the border. But this double printing may be overdone; the outside framing, if one may so term it, should be sufficiently deep to afford a slight contrast to the pure whiteness of the picture and the paper immediately in proximity with the vignettied group, but should not be deeper than the lightest shades. Remember that you are not printing a framework, but only a slightly tinted mount.

Types of Groups.

If this method is effective for the group proper, the group that has been built up according to the best recognised canons of art, it is just as effective when modified to suit groups which do not consist of being built up in the most orthodox fashion. Two typical examples can be easily given and may serve as models or illustrations, types rather, of more or less important gatherings. The first I will mention is the military group. I put it first, not because it is the most common or the most important, but because it is the simplest. No photographer in his sober senses would dream of putting the General, the Colonel, or the Captain, or whomsoever was highest in rank, anywhere but in the centre. The highest in rank must, in the parlance of art exhibitions, be hung on the line. The officers of next importance may stand behind their seated superiors; the tallest in the centre, if possible, but that is of little moment, and the differences in height are not likely to be striking. As to the subalterns, you

may seat them on the grass in front, and very well satisfied they ought to be in being portrayed in such distinguished company at all. The naval group would be similarly arranged; what may be called the Service type of group is the type of any course of servants, military, naval, civil, or otherwise. Art must be subordinated to rank and even looks. The group often takes the form of a horizontal oval whether the artist wishes it or not.

The second illustration is of the family group type, of which the wedding party is the best example. This assumes, most often, the cushion-shaped form, and happy for you if you have a little flower girl or two to put in the foreground so that you can obscure the hang of the groom's new trousers and the shine of his patent boots. But grouping is not the subject of these columns, and the little digression with which I have concluded is merely to emphasise the use to which masking and double printing may be put in effectively finishing off a vignettied group.

C. RAY WOODS.

THE WEEK IN HISTORY.

The Dry Plate of Fifty Years Ago.

I HAVE referred very often, it seems to me, to the dry-plate processes that bridged over the era of wet collodion and gelatino-emulsion. There was Crookes' and Spiller's ("The Week in History," April 28), and in the same year of 1854 the honey process was worked out independently by George Shadbolt and Maxwell Lyte. Here again the idea was to preserve the humidity of the plate until development could be done. A year later, and exactly fifty years ago to-day, a dry-plate process which came into considerable vogue in the late fifties was published by Dr. J. M. Taupenot ("La Lumière," September 8, 1855), and, after albumen, was the first dry plate process to reach the boundaries of experimental success and obtain adoption among practical photographers. M. Taupenot's method arose from his observation that a film of albumen, coagulated by an acetic acid solution of silver nitrate, formed an excellent varnish for collodion plates, and he set himself to apply the albumen to the preservation of sensitiveness when the collodion was used dry. His process was not complex. The collodionised plate, after immersion in the nitrate bath in the usual way, was rinsed in distilled water, and an albumen solution containing $\frac{1}{2}$ per cent. of iodide poured over it. After drying, the plate could be kept for several days. To prepare it for exposure, it was placed for ten or twenty seconds in a bath of acetic acid and silver nitrate, rinsed in distilled water, and exposed, either whilst still wet or up to the day following its preparation. The plate was developed by a saturated solution of gallic acid containing a little silver nitrate and acetic acid, and development might occupy a quarter of an hour or several days.

The Last Dry-plate Process.

September 8 is the red-letter day of modern photography, for it marks the publication, in THE BRITISH JOURNAL OF PHOTOGRAPHY, of the description of an attempt to compound a practically workable gelatino-bromide emulsion. Discussion has raged fiercely around the invention of the gelatine dry process, but without disparagement of the labours of others, the honour of inaugurating the present era of photography belongs to Dr. R. L. Maddox, whose communication in the B.J. for 1871 I have just mentioned. The first emulsion formula was described as follows:—

"Thirty grains of Nelson's gelatine were washed in cold water, then left to swell for several hours, when all the water was poured off, and the gelatine set in a wide-mouthed bottle,

with the addition of four drachms of pure water and a few drops of *aqua regia*, and then placed in a basin of hot water for solution. Eight grains of bromide of cadmium, dissolved in half a drachm of pure water, were now added, and the solution stirred gently. Fifteen grains of nitrate of silver were next dissolved in half a drachm of water in a test tube, and the whole taken into the dark room, when the latter was added to the former slowly, stirring the mixture the whole time. This gave a fine milky emulsion, and was left for a little while to settle. A few plates of glass, well cleaned, were next levelled on a metal plate put over a small lamp. They were, when fully warmed, coated by the emulsion, spread to the edges by a glass rod, then returned to their places and left to dry. When dry, the plates had a thin opalescent appearance, and the deposit of bromide seemed to be very evenly spread in the substance of the substratum."

Emulsion makers will see that this formula leaves a slight excess of silver in the emulsion, and is further open to very serious objection from the employment of *aqua regia* in its composition. Dr. Maddox gave no instructions for washing his emulsion free from the products of the reaction by which the silver bromide was formed, and so he had silver nitrate and nitric acid as well as sodium bromide in his final product. Hence his emulsion was unstable, and lost a great deal of its sensitiveness within a few days of preparation. Dr. Maddox tested its properties by exposing his plates under negatives:—"The exposure varied from thirty seconds to a minute and a half, as the light was very poor. No vestige of an outline appeared on removal from the printing frame. The plates were dipped in water to wet the surface, and over them was poured a plain solution of pyrogallol acid, four grains to the ounce of water. Soon a faint but clean image was seen, which gradually intensified up to a certain point, then browned all over; hence the development in the others was stopped at an early stage, the plate washed, and the development continued with fresh pyro, with one drop of a ten-grain solution of nitrate of silver, then re-washed and cleared by a solution of hyposulphite of soda. . . . Some plates were fumed with ammonia; these fogged under the pyro solution."

Crude as this first gelatine emulsion appears in comparison with the products of modern skill and knowledge, it nevertheless was the germ from which sprang the later refinements of the emulsion-maker's art. The first step towards the dry plate as we now know it was the appearance of the ready-made emulsion of Mr. Burgess ("The Week in History," July 21).

The Birthday of Collodio-Bromide.

The collodio-bromide emulsion process—I am dwelling among emulsions this week—attains the ripe age of forty-one years to-morrow, for it was on September 9, 1864, that the paper by its authors, Messrs. Sayce and Bolton, appeared in *THE BRITISH JOURNAL OF PHOTOGRAPHY*. "Photography without a nitrate of silver bath" was a headline to conjure with in the sixties, when the troubles of wet collodion were severely felt by those not completely masters of the process. The attitude of the landscape or portrait photographer who looked upon his process as a means to an end is boldly sketched in a characteristic letter from O. J. Rejlander to the B.J. in July, 1864. " . . . Enlist the services of all the photographic world how to make collodion sensitive without the nitrate of silver bath. . . . No more draining lines, nor crape, nor 'stars and stripes,' nor comets! and no more pinholes where no pin ever pricked. Oh, go it, Dawson!" Messrs. Sayce and Bolton experimented to this end, and their first result, imperfect though it was, was an important step in the direction in which Dr. Maddox afterwards moved, but with gelatine instead of collodion as the medium of the emulsion. The first bromised emulsion, as prepared by Sayce and Bolton, was as follows:—

Alcohol	$\frac{1}{2}$ oz.
Bromide of cadmium and ammonium	3 gr.
Pyroxyline	2 gr.
Ether	$\frac{1}{2}$ oz.

Well filtered.

The authors proceed: "We then took an ounce phial, placed therein four grains of pulverised nitrate of silver, which was dissolved in two drops of distilled water, then covered the bottle with a perfectly non-actinic coating of brown paper and in a yellow light added the ounce of bromised collodion. The mixture at once produces milkiness, which does not disappear. We then shook the bottle and coated a clean glass—previously tipped at the edges with benzine and indiarubber solution—with the collodion, without even allowing it to settle, and allowed the film to set in the ordinary manner; then placed the plate, face upwards, in a dish of water, and when the greasy appearance of the film had vanished, rinsed under the tap for a few seconds, then poured over the film the ordinary fifteen-grain solution of tannin, worked it well into the film for about one minute, and dried rapidly in a kitchen oven." This first emulsion was weak, but the inventors at once increased the silver bromide in it, with such good results that of a photograph taken with double the proportion of bromide of silver Mr. Sayce wrote on September 14:—"It is indeed very fine, and would do credit to even any matured photographic process."

"Photography without a nitrate of silver bath" made rapid progress after its first inception. Mr. W. B. Bolton was chiefly responsible for the early improvements, and his name figures prominently among others until 1874, when, as I have already chronicled, he introduced the "washed emulsion" process.

HISTORICUS.

SOME NOTES ON THREE-COLOUR WORK.

[Although a great mass of technical literature makes its appearance with three-colour work as its subject, the greater proportion of the contributions deal with the first principles of the process, or with the endless modifications which worker after worker introduces or proposes. It is rare to find a writer setting himself the task of putting on record any experience in the actual routine of three-colour as it occurs in practice. We therefore abstract some notes in this strain which we find in "Photographische Kunst," from the pen of Dr. E. Stenger. Some of Dr. Stenger's anticipations may seem premature, but that there is need of keeping closely in touch with progress which will reanimate the photographer's professional business none of our readers, we are sure, will dispute.—EDS., B.J.P.]

Present-day Possibilities.

TAKING three-colour photography as it is at the present time, there is good reason for assigning to it an important position among photographic processes. The future may bring simplifications and improvements, and possibly processes which depend on principles other than those recognised to-day, but at the present instant indirect three-colour work is in a state in which all those who are disposed to embark upon it need not be deterred by the greatness or difficulty of the task. The technical part of the process has been so fully worked out and brought to a condition of simplicity that it entails only a modified use of the methods which have been long practised in ordinary black-and-white photography. Three-colour work is now finding a footing among professional photographers, and perhaps the time is not so far distant when the public will not be satisfied with portraits in monochrome. This step, from black to colour, seems to be very little greater than that which marked the transition from the bygone conventional portrait to the method of to-day, in which the photographer aims at character and likeness.

A Study of Paintings.

A good deal is to be learnt in regard to the selection of the subjects for three-colour photography by studying the work of

painters. A good painting of a subject to which the photographer has access should be of direct assistance to him. One notable difference between the art of the painter and of the photographer should constantly be kept in view, viz., the ability of the former to omit disturbing portions of his subject, and the obligation of the latter to take things as he finds them. Colour, which in black-and-white photography can be reproduced only by varying degrees of luminosity, becomes, of course, in three-colour work the most active agent in the formation of the picture. In ordinary photography we aim at a scale of gradations in monochrome in the picture, but in colour photography we obtain these scales of tone in all colours. Hence in three-colour work the means at the disposal of the photographer are incomparably greater, and the best manner of employing them demands a special study of colours and a trained eye.

A Plate of Small Size.

The photographer is accustomed to arrange his subject without special regard to its colours and to avoid the occurrence of empty spaces of considerable area, which latter, however, in colour work are an advantage to the picture, as they provide a spot upon which the eye can rest. Excess of detail in various colours, impart a disturbing character to the picture, and, with a view to avoiding them, it is advisable to unite the larger monochrome portions of the picture, and especially is it important not to crowd too much on to the plate. In other words, the familiar maxim of making the picture with as little material as possible is more than ordinarily applicable in colour work. A convenient camera must necessarily carry a plate of small size, and, having regard to the provision of filters, etc., it is rarely possible to work on a larger plate than 9 by 12 cm. ($3\frac{1}{2}$ by $4\frac{3}{4}$ in.). On this account special care is needed in arranging the subject, as subsequent trimming of the print, or enlargement of portions of it is inadmissible.

Choice of Focal Length.

There is also an advantage in selecting a lens of focal length greater than customary, in relation to the plate, the subject being

then obtained of good size, and accompanied to a lesser extent by unnecessary detail. Prof. Miethe uses a lens of 16.3 cm. ($6\frac{1}{2}$ in.) for a plate 8 by 9 cm. ($3\frac{1}{4}$ by $3\frac{1}{2}$ in.), this corresponding to an angle of nearly 31 deg., whereas in the ordinary way one chooses focal length about equal to the diameter of the plate, in the above instance 12 cm. ($4\frac{3}{4}$ in.). Prof. Precht uses lenses of 11 and 12 cm. ($4\frac{3}{8}$ and $4\frac{1}{2}$ in.) focal length for a plate 6 by $6\frac{1}{2}$ cm. ($2\frac{3}{8}$ by $2\frac{5}{8}$ in.), these lenses covering angles of 33 and 30 deg. respectively. The diagonal of the plate used by Dr. Precht is not quite 9 cm. The value of the smaller plate lies in the fact that lenses of shorter focal length can be used over the same angle, thus obtaining greater depth of field, and permitting the employment of a large aperture. In fact, the working of a lens at its full aperture is in many cases an essential to success in three-colour exposure.

Subjects for Three-colour.

The beginner in three-colour work will find himself passing over many profitable subjects to select others, such as extended landscapes, etc., without obtaining satisfactory results, until he discovers that the most suitable subjects are those of a simple kind, such as a house in green surroundings, a pond in a meadow reflecting the blue sky, etc. Brilliant pictures are obtained by the conjunction of highly contrasting colours, an artifice to which the modern painter will often be seen to resort. The student will also be repaid by a course of exposures on still-life subjects, for after this practice he will quickly learn to discover profitable subjects out of doors. Practice is no less necessary in development. In three-colour work it is no easier than in black-and-white photography to obtain white clouds on a blue sky side by side with a fully exposed landscape.

Lighting.

We must not omit to emphasise very strongly the difference between the rules by which the photographer has been accustomed to guide himself in regard to lighting, and those which will serve him best in three-colour work. The hours of early morning and late evening, usually little employed for photography, offer the best opportunities for three-colour. Brilliant noonday sunshine, with its hard shadows, is a bad lighting, and leads to wrong colour reproduction. The easiest and most hopeful field for the unpractised worker is that in which colours occur fairly equal in inten-

sity. If the contrasts are excessive, a kind of halation creeps in as in ordinary photography. It must be remembered that a rightly graduated reproduction of the colours depends upon each plate showing the proper gradation on development—that is to say, having a density of silver deposit corresponding to the colour and the exposure, which density should be less than the maximum permitted by the plate. Intensities of colour which are represented in the negatives by the greatest possible darkening of the separate plates do not give proper gradation in the component colours, with the result that on synthesis by means of positives incorrect colours are obtained.

Landscape.

In landscape it is unfortunately obligatory on the photographer to confine his work to occasions when there is no wind, otherwise the separate impressions will not register. Instantaneous photography is practically ruled out of court in three-colour work, as the three exposures must be made consecutively. It was often found that subjects which, from the point of view of monochrome work, are most promising, are useless in colour photography, owing to the length of exposure. Posing models are easily placed in position, but it is best, on the whole, to dispense with them, as they usually look artificial.

Portraiture.

The contrasts between light and shadow are greater upon the photographic plate than they appear actually to the eye, and in order to obtain soft portrait negatives with detail in the shadows the photographer must lighten these portions with suitable reflectors. For three-colour work this evening up is all the more necessary when the intensity of the several colours is to be as equal as possible. Portraits of men in modern costume offer little in the way of colour; ladies' clothing, on the other hand, offers more opportunity. It will frequently be found that a portrait in colours of a person represents him or her as too tall or stout. Hence it is advisable to arrange the figure somewhat smaller in relation to the size of the plate, and to take care also that the model is sufficiently removed from the background and immediate surroundings. The ordinary neutral background as usually used in studios is unsuitable for colour work, but a back cloth of a slightly contrasting colour usually answers well.

SELECTING PHOTOGRAPHS OF THE OLD MASTERS.

HARDLY a national or state photographers' convention is allowed to pass by without some one urging those present to "study the old masters." Unfortunately this exhortation, however sincere and well-meant (writes Wilfred A. French in the "Photo-Era"), is not accompanied by a suggestion as to how this study of the old masters shall be accomplished, short of a sojourn in foreign lands, where the best creations of art are to be seen. The American galleries are woefully deficient in original works by Rembrandt, Velasquez, Reynolds, Sargent, and other notable portrait painters, and a journey to Europe is a luxury reserved to exceedingly few of the craft, while most of those able to gratify such a desire lack the ability to put the experience thus gained to profitable use. The only alternative is recourse to photographs, and of these the best are not always available. Yet if the ambitious photographer is really in earnest, he can either purchase a series of photographs from negatives made on colour-sensitive plates, or induce the public library—and there should be one in every well-regulated community—to secure for its permanent use such a collection, which should be easily accessible to students. Orthochromatic photographs of the gems of the leading European picture galleries are made not only

by Braun, Clement, and Co., pioneer publishers of faithful photographs of the old masters, but by Hanfstaege of Munich and the Berlin Photographic Company; also by Brogi, Alinari, and Anderson—the leading publishers of art photographs in Italy—and Hollyer, of London, several of these having branch establishments in New York city.* We would suggest that every photographer make a personal effort to procure a series of such photographs for himself, say of moderate dimensions, the cost of the 8 by 10 size, mounted, being comparatively small.

Good and Bad Reproductions

The great trouble with many cheap photographs of celebrated paintings is their inferiority of workmanship, which destroys the detail and tonal gradations, and consequently the fidelity to the original picture, the resulting prints being excessively harsh in light and shade, and of little or no artistic value. This is particularly true of reproductions of imported photographs, the process of copying showing no evidences of technical skill. We have in mind also a popular

* Photographers in this country are no doubt familiar with the large and excellent series of reproduction in carbon of old masters published by the Autotype Company.—EDS. B. J. P.

series of half-tones, the cheapness of which is their sole merit, for they rejoice in the defects just described to an excessive degree. While they may serve the purpose of familiarising the masses with places of historical interest, famous personages, and standard works of art, they are really of no use to the photographer craving reliable knowledge regarding masterpieces in painting. Yet such prints, which totally misrepresent the appearance of the original pictures, have been studied and emulated with sedulous care by photographers, who proudly display what they sincerely regard as "Rembrandt" or "Velasquez" lighting, when in reality they are, metaphorically speaking, working in the dark—far from the truth. This accounts, in a measure, for the total absence of outline of the figure, from the head down, characteristic of so many otherwise excellent photographic portraits, the originators of which assert, with more warmth than truth, that they are only following the example of Rembrandt, the great Dutch painter. For the benefit of these workers, who are obviously unacquainted with the original paintings which inspire them to high flights of fancy, we are constrained to state that the creations of Rembrandt are not mere dashes in black and white, as inferior photographic reproductions would have us believe, but are sincere expressions of artistic genius, marked by logically correct, though original, chiaroscuro, with adequate tonal gradations in the flesh-tints, and the figure is not only outlined with clearness, but the drapery, generally black or of a dark colour, is painted with suitable detail. This is true of such favourites as "Johann Sobieski," "Saskia van Uylenburgh," "The Lesson in Anatomy," the so-called "Night-watch," and the numerous portraits of the artist, so well-known through photographs to the majority of workers in this country. The above applies with equal force to works of other artists noted for strong chiaroscuro, including Hals, Rubens, Van Dyck, Velasquez, and Murillo. By comparing an inferior photographic reproduction of a certain painting with a carbon print by Hanfstaengl or an equally reliable art-publisher, one will at once perceive the difference in the direction we have indicated and appreciate the characteristic harmony, clearness, and beauty of the result attained by the use of colour-sensitive plates.

ART BY PHOTOGRAPHY.

ON Thursday last an exhibition of the collection of pictures, which represented British photography at the St. Louis Exhibition, was opened at the Rochdale Art Gallery. The pictures have been conveyed to Rochdale *en bloc* from the Leeds exhibition, and they are attracting considerable attention in their latest environment. At the opening ceremony the Rev. H. W. Dick, vice-president of the Manchester Amateur Photographic Society, gave an address on "Art by Photography." After endeavouring to define art and the artist, he said:—"That which made a man an artist had so much relation to his quality of mind that he might be, to all intents and purposes, an artist without being able in any way to give outward expression to what was within him. The term art, therefore, ought not to be bound up with any particular mode of expression. If he were asked if photography were an art, he should say not; but he should give the same answer if he were asked whether painting or sculpturing were an art. The medium had nothing whatever to do with the man. The artist chose that medium which suited him, and by which he was best able to express himself. It was not the medium he chose which made the artist. Photography was not art, but the photographer might be an artist, just as the painter might be. Neither the painter nor the photographer was always an artist. Art lay within the soul and the mind of a personality, and he was an artist who, having that quality of soul, could express it, whether in paint, or marble, or any other medium. It might be said that photography had its limitations—that they were obliged

to take what was before them. They need not do that, because they could walk away, but if they did take what was before them, there were ways of printing which enabled them to print just so much as they desired. Some prints were built up just as a painter would build up a picture. They might print and develop again and again, give emphasis where they desired it, and make the resultant print quite as unlike nature as Turner was capable of making his pictures unlike nature. The artist was not the man who painted or photographed just what he saw before him; no artist ever did paint or represent just what he saw. He represented what he would like to see and what he felt; he gave the gospel of nature according to himself. It was nature passed through a personality which they got in a real picture.

FORTHCOMING EXHIBITIONS.

September 8.—International Exhibition at Budapest. Address, Secretary of the Photo-Club, Egyetem-ter 5, Budapest, IV.

September 15-October 21.—Photographic Salon, 5a, Pall Mall East. Hon. Secretary, Reginald Craigie, Camera Club, Charing Cross Road, W.C.

September 21-October 28.—Royal Photographic Society, New Gallery, 121, Regent Street, London, W.—Secretary, J. McIntosh, 66, Russell Square, London, W.C.

October 17-18-19.—Isle of Wight Photographic Society. Hon. Sec., V. Howard Burgess, 53, Pyle Street, Newport, I. of W.

October 18-21. Rotherham Photographic Society. Hon. Secretary, H. C. Hemmingway, Tooker Road, Rotherham.

October 19-21.—Grangemouth Amateur Photographic Association. Hon. Secretary, Robert Marshall, 3, Park Terrace, Grangemouth.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

November.—Edinburgh University C.C. Hon. Secretary, Harold C. Simpson, University Union, Edinburgh.

November.—Bristol and Clifton Arts and Crafts Society. Secretary, R. H. Parr, 5, Grove Buildings, Blackboy Hill, Bristol.

November, December, January.—Second American Photographic Salon. H. Snowden Ward, 6, Farrington Avenue, London, E.C.; Wm. T. Knox, 279, Washington Street, New York City, U.S.A.

November 3, 4, 5.—Motherwell Young Men's Institute C.C. Hon. Secretaries, James Dunlop, Myrtlebank, Motherwell, and Archibald Matthews, 24, Enfield Place, Ladywell, Motherwell.

November 8-15.—Croydon Camera Club. Hon. Sec., W. H. Rogers, 88, Woodville Road, Thornton Heath.

November 14, 15, 16.—Ipswich Camera Club. Hon. Sec., R. H. Sutton, 37, Henley Road, Ipswich.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

November 23-25.—Isle of Thanet Photographic Society, Hon. Sec., L. G. Hodgson, 58, Queen Street, Ramsgate.

November 25-December 2.—Glasgow Eastern A.Ph.A. Hon. Secretaries, Thomas B. Kirkhope, 37, Winston Street, Parkhead, Glasgow, and John Brough, 68, Dalmarnock Street, Parkhead, Glasgow.

December.—Muirkirk A.Ph.A. Hon. Secretary, William Barrowman, Ayr View, Muirkirk.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 6-7.—Watford Camera Club. Hon. Secretary, E. H. Jackson, 100, High Street, Watford.

Photo-Mechanical Notes.

British Process.

THE son of a colonial printer and photo-engraver at present in England to improve his knowledge of process work recently obtained a situation in one of the London shops, whereupon he writes us:—"The amount of work turned out in a day surprised me, the originals just seem to pour in, good, bad, and indifferent, and the way they photo them, all kinds together, greatly amazed me." According to recent visitors, even the Americans have not much to teach the old country as far as "hustle" is concerned in the photo-engraving trade.

"True Scale" Photo Litho.

To those who have difficulty with the "Vandyke," or similar direct processes, we can recommend a way which is as quick, if not quicker, and the results are quite equal to the average work done by the reversal processes. That is to make a sepia negative from the original tracing, or drawing, by contact, and then, without fixing, use this to make the usual albumen print, which is inked up, developed, and treated exactly as a print on metal for line work or photo-lithography. Of course, the negative, being unfixed, can only be used once: the objection to fixing it is that the paper alters in size from the wetting, and another objection to this method is that the ink is not in such direct contact with the metal as with the other processes, there being a thin film of bichromated albumen between, and this is disliked by some lithographic printers as tending to allow the work to lift sometimes.

Half-tones in Newspapers.

Some half-tones of comparatively fine screen-ruling are now appearing in the Gloucester "Citizen" by a process of backing the blocks worked out and patented by Messrs. Chance and Bland, of that office. The results as we have seen them are excellent for the class of work, and quite distinct from the highly tooled block employed largely in newspaper work. A circular from the inventors gives the following particulars of the process:—"Those parts of the plate to be fixed to the cylinder (the forme) where the illustrations are to appear are set up as blank spaces preparatory to the casting of the plate. After the plate has been cast, and before it is mounted on the cylinder, these blank spaces may be cut out and the blocks of the illustrations inserted. It is, however, preferable to make the blank space whilst casting the stereo, putting in an iron block or plate that is afterwards easily removed. With this construction it is possible to adjust the block irrespective of the type, and therefore the impression from the block is clear, and renders the character of the original much better than is the case where the block forms part of the whole stereo. We claim by this invention to have made it possible to produce good pictures, greatly superior in tone and texture to any that can be reproduced by stereotyping, in plates cast for use upon rotary printing machines. The plant required is practically nothing, and the delay caused in inserting the picture in the plate cast, according to the instructions, is reduced to a minimum. No special skill is required either from the stereotyper or the machinist, and pictures of a fine grade can be printed at the usual rate at which the printing machine is run. If ordinary good paper is used there is no necessity to stop for washing out in the longest run on the machine."

The L.C.C. School of Photo-Engraving.

The prospectus of the Bolt Court School for the coming session is to hand, and we note that work will commence earlier this year than hitherto, the school opening on Monday, September 18. Besides the usual curriculum, there is a new class in "Mounting."

The equipment of the school has lately been added to and brought up to date. It now includes a machine room containing the latest

FORTHCOMING COMPETITIONS.

September 30.—Kodak. £400 in prizes for results on Kodak products. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 in prizes for photographs taken with Thornton-Pickard cameras or shutters.

October 15.—Lantern Slide Competition, Association Belge de Photographie. Secretary, Palais du Midi, Brussels.

October 31.—"Zigo." Cash prizes for prints on "Zigo" self-toning paper. Thos. Illingworth and Co., Limited, Willesden Junction, London, N.W.

November 30.—Royal Photographic Society "Affiliation" Print Competition. Particulars from the Secretary, 66, Russell Square, W.C.

December 30.—Royal Photographic Society "Affiliation" Lecture Competition: (a) Illustrated lecture descriptive of a tour (b) Illustrated technical lecture. Particulars from the Secretary R.P.S., 66, Russell Square, London, W.C.

February 6-9, 1906.—Guisbrough Fine Art and Industrial Society, Photographic Section. Hon. Sec., G. H. Angus, 34, Westgate, Guisbrough.

A PHOTOGRAPHIC competition is held annually by the Architectural Association Camera and Cycling Club, and is open to all members of the architectural profession. The council of the association offer a prize of three guineas for the best set of prints submitted. The competition is confined to sets of photographs adapted for the purposes of architectural study. Photographs must be sent to Mr. F. R. Taylor, secretary of the A.A. Camera and Cycling Club, at 18, Tufton Street, Westminster, not later than October 1. Mr. Taylor will supply full particulars.

power machinery for mounting, router, beveller, saw, etc., block proving room with electric motor-driven platen machine, mercury-vapour lamps in the studio, etc. The syllabus includes classes in every branch of the reproductive crafts.

A special feature is made of the courses of lectures. Our contributor, Mr. C. E. Kenneth Mees, gives a course of five lectures on "The Chemistry of Photo-Engraving," Mr. Sunderland, of Sir George Newnes, Ltd., gives a course of lectures on "Duplicate Plate Making," and among the other lecturers we observe Mr. Carl Hentschel, Mr. Arthur Cox, Mr. Edwin Bale, R.I., Mr. E. F. Strange, Mr. F. T. Corkett, Mr. E. W. Foxlee, and Mr. Wm. Gamble. It is probable that everyone in the trade could take advantage of some part of the school's activities. A copy of the prospectus can be had for the asking at 6, Bolt Court, E.C.

A Comprehensive Process Catalogue.

The new issue of the price list of requisites for photo-engraving and other photo-mechanical processes, now issued by Messrs. A. W. Penrose and Co., is a large and handsome volume of over 340 pages, fully descriptive and freely illustrated. It would be well-nigh impossible to find a solitary appliance or material for half-tone, colotype, photogravure, etc., which is not listed by Messrs. Penrose, and the large variety of goods is conveniently classified into sections, the finding of which is facilitated by a system of thumb-notching of the pages. This and a very full index make the task of reference an extremely light one. We are glad to see that in a very large number of instances the list gives sizes and weights in metric as well as in English equivalents. Thus, under "Bottles" we find alongside the capacities in ounces the number of ccs. the vessels contain, a procedure which must have the desirable effect of familiarising people with the metric measures. Prices are also quoted in dollars, francs, and marks, as well as in English money. Evidently Messrs. Penrose are determined to place no obstacle in the way of customers in any part of the globe. The catalogue is obtainable post free from 109, Farringdon Road, London, E.C., for 2s. 6d., which amount is refunded on the first order for £1 and upwards.

PHOTO-MECHANICAL PATENTS.

Application for Patent.

No. 16,935. Improvements in the production of plates for printing purposes. Sherard Osborn Cowper-Coles, 4, South Street, Finsbury, London.

THE KODAK £400 COMPETITION.—Messrs. Kodak have asked us to remind our readers that their forthcoming £400 competition closes on September 30. The following points should be noted by intending competitors:—(1) No limitation has been placed upon the number of prints that may be sent in by any competitor; (2) photographs of every description will be eligible, but there are no special classes for portraits or landscapes, or other particular subject; (3) no distinction will be made between snapshots and time exposures, both competing on equal terms; (4) on no pretence may any but pictures taken with a Kodak on Kodak N.C. film be entered; (5) photographs taken in any other camera or on Kodoid, Seed, or Eastman plates will not be eligible; (6) the nature of the mounts is left entirely to the competitor, but either paste-on or slip-in mounts may be employed; (7) not more than one contact print from a negative may be entered in the competition, but there is nothing to prevent an enlargement and a contact print of the same negative from being entered in their respective classes.

ANOTHER selection of photographic studies from Kodak negatives taken by Her Majesty the Queen appears in the current number of "The Graphic."

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes.

The following applications for patents were made between August 21 and 26:—

CINEMATOGRAPHS.—No. 16,925. Improvements in cinematographs. Robert Royou Beard.

TRIPODS.—No. 16,963. An improvement in relation to tripods. George Allen Walker, Gough Street, Savile Street, Hull.

FILMS.—No. 17,000. An improved photographic film. Leonard Smith, 53, Chancery Lane, London.

PRINTING PROCESS.—No. 17,807. Improvements in photographic printing. Thomas Manly, 23, Southampton Buildings, Chancery Lane, London.

SHUTTER RELEASE.—No. 17,127. An improved pneumatic release for photographic shutters. Houghtons, Ltd., and Alfred Sydney Spratt, 88, High Holborn, London.

MERCURY VAPOUR-LAMPS.—No. 17,183. Improvements in mercurial vapour electric lamps. Joseph Swirsky and Francis Harrison, 157, Grange Park Road, Leyton, Essex.

PAPERS.—No. 17,303. Improvements in the manufacture of photographic papers. Ignaz Hoffsummer, 6, Lord Street, Liverpool.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

DATLIGHT DEVELOPMENT.—No. 17,244, 1904. The patent describes an apparatus in which plates, cut-films, or roll-films can be developed in daylight. It consists of an inner and outer vessel, the inner vessel having a light-tight cover. Plates or cut-films are placed in sheaths. For the purpose of treating roll films in the strip or band, both inner and outer containers may conveniently be of a cylindrical shape. James Wyndham Meek, 32, Albert Road, Stroud Green, London.

CINEMATOGRAPE.—No. 17,347, 1904. According to the description of this invention a rotatable member is arranged within a flat case, and carries a radially projecting spring or other yielding driving arm of such a length that its outer end engages, or abuts, against a series of studs or pegs, arranged concentrically about the rotatable member. These studs are fixed within the case and arranged at equal distances apart, their number corresponding to the number of pictures it is desired to take or exhibit. As the spring arm is rotated its outer end is temporarily arrested by each stud in turn, thus giving the desired stationary period for the sensitive film or positive picture as the case may be, the film or picture record being made in the form of a disc and adapted to be rotated intermittently by the outer end of the spring. The individual pictures are located near the edge of the disc, being received or viewed through a suitably arranged opening in the casing. When the apparatus is used for taking the pictures on a sensitised film, a shutter disc is superimposed on the film and adapted to be rotated in conjunction therewith so as to expose the desired portions of the film during the stationary periods. Samuel Henry Crocker, 9, St. James' Walk, London.

CAMERA FITTINGS.—No. 17,408, 1904. This patent relates to several improvements in photographic cameras, viz.: (1) Swing back with double adjustment, whereby the swing back, after having been once adjusted, can be lowered in the desired position by a single locking device. The swing back is provided with two

studs or adjusting arms on each side, namely, a horizontally disposed arm or slide on each side to which the swing back is pivoted at one end, while the other end of each horizontal slide is slotted and guided in grooves or guide-ways on the inside of the body of the camera, so that a parallel movement only is permitted of the horizontal slides; a pin or pinching screw passes through the slot in these horizontal slides, and the inner

end thereof passes through a slot in the inner end of a strut at each side, which strut is disposed more or less diagonally to the horizontal slide, and at its outer end is pivoted to the swing back. (2) Adjustable infinity catch. The catch is mounted on a slide consisting of a thin, slotted metal plate, which, by means of one or more adjusting screws, can be adjusted and fixed in any suitable position on the folding base-board. (3) Swinging front with view-finder attached. The present inventors have discovered that numerous advantages are obtained by arranging and mounting a view-finder upon a swinging front of the character set forth in Houghton and Edwards' Patent No. 23,436/03; namely, by such combined means it is found that when a view finder is used on such rising front the image indicated on the view-finder will be precisely identical with that given by the lens on the sensitive surface (upon exposure taking place), this result following from the fact that the view-finder is correspondingly moved by and with the special swinging movement. The figure is a side view of a folding camera with view-finder attached, and shows the lens in two positions. 17 is the view-finder carried on the rising front, 18, of the camera. 19 19 are the front standards which support the rising front carrying the lens. 20 20 are the guiding studs sliding in the slotted standards 19. These slots in which the studs run freely instead of being in vertical alignment are so formed that the lower ones slope upwards and outwards for the purpose of keeping the optical axis of the lens directed to the centre of the sensitive plate when the front is raised. (4) Attachment of bellows to lens front. Instead of the usual attachment by glue the front end of the bellows is folded over a loose plate, advantageously a metal plate of the same shape as the bellows, and the edges of the bellows secured by gluing together the folded over corners of the bellows, this plate being thus secured in the front fold of the bellows, and being provided with an aperture sufficiently large to admit the lens, etc., to pass through. The lens front is provided with a corresponding aperture of sufficient size to permit a flanged ring or short flanged sleeve to pass through, the cylindrical part of the ring or sleeve being screw-threaded both internally and externally, the internal thread being adapted to have the lens or lens carrier screwed into it, while the external thread (which passes freely

through the aforesaid aperture in the lens-front and through an aperture in the plate mounted in the front fold of the bellows) receives a locking ring, secured from the inside of the bellows, and thus drawing up the sleeve tightly in the front. (5) Arm for lens front. In folding bellows cameras of the type where the bellows and lens-front are packed closely into the camera body and the hinged front then closed over same, there is usually employed a lever or arm for moving and locking the lens-carrying front. This arm usually has the disadvantage that when the lens-front and bellows have been moved back into the camera body the arm requires to be turned to one side or the other in order to permit the folding base-board to be closed; and, if the operator forgets to move the arm, damage may be caused. This part of the invention consists in so constructing the arm that upon release it will automatically move to one side or the other out of the way of the hinged door; for example, the arm may be provided with a spring sufficiently strong to fold or force it out of the way when it is released. Houghtons, Ltd., 88 and 89, High Holborn; William Albert Edwards, 51, Vant Road, Tooting; and Herbert Holmes, 9, Ashby Road, Canonbury, London.

LENS AND DIAPHRAGMS.—No. 18,694, 1904. The invention consists in a diaphragm, or diaphragms, moved before the lens during exposure, the object being to produce diffused or softened definition. The claim is for discs of certain shape and for the mechanism by which their movement in the lens is produced and regulated. Theodore Brown and Ernest Osman Brown, 34A, Castle Street, Salisbury.

FILM DEVELOPMENT.—No. 21,335, 1905. The following is the inventor's description (abridged) of his system of developing roll film:—I provide a coil or helix of metal possessed of sufficient resiliency to permit of the spool of exposures being readily passed

through the coils of the helix, and the helix thereafter assuming its original dimensions and width of gap between the coil. On the outer circumference *a* of the helix or coil *b* (which, when in use or after use, is placed in a circular tank of sufficient size to freely enclose the helix) a clip or other suitable device *c* is attached, to which the end *d* of the black paper wrapping *e* of

the spool *f* is fixed. In practice, the end *d* of the black paper *e* is attached to the clip *c*, and the end of the film *g* having been attached to the black paper by means of adhesive paper *h* or in any other method, the spool *f* is then placed upon the outer circumference of the coil and rolled along same in a direction away from the securing device holding the end of the black paper as in fig. 2 in such a manner that the black paper (and film attached thereto) is unrolled upon the coil with the sensitive surface of the film outermost and with the black paper lying between the film and the coil or helix. The spool is rolled along the outer surface of the coil towards the point of entry, see fig. 2, into the coil, so that the spool or cartridge *f* will run into and not over such point of entry into the coil. At this point the outer coil of the helix is pulled somewhat apart from the next so as to permit the spool or cartridge to enter the coil. This performed, the spool is gripped by the flanges by the fingers of one hand while the coil is held in the other hand, and in this manner the spool, fig. 3, is rolled into the helix until the centre *i* is reached, fig. 4. In so doing the spool traverses the whole of the coil or helix and unrolls the film previously wound upon the spool, so that the whole length of the film lies upon the coils of the helix with the sensitive surface of the film on the outside throughout and touching neither itself nor the supporting coil at any part. The centre *i* of the coil is a clear annular space of a diameter sufficient to hold the spool (and unrolled black paper) without in any way exerting pressure upon the coil when the spool has reached such annular centre space. This performed, the film is in position for developing and fixing, which operations may be carried out in any dish holding a sufficient depth of the various solutions. It is released simply by cutting the black paper loose from the securing device, and also removing the spool and waste black paper from the centre of the coil, the film itself and underlying black paper being thereafter withdrawn from the coil by gently pulling the film and black paper up edgewise, as in fig. 5, free of the coil. James Wyndham Meek, 32, Albert Road, Stroud Green, London.

Dew Materials.

Herold's Powder Emulsion and Litho Gelatines, sold by Otto Rosenstiel, 104 and 105, Cheapside, London, E.C.

These brands of gelatines, the manufacture of Mr. Julius Herold, of Monsingen, are supplied in powder, thus facilitating the solution of the colloid and saving time, whether the gelatine be employed for emulsion making or lithography. One sample examined by us on an experimental scale proved to be a good hard gelatine of melting point 91.5 degrees F. (mean of six tests). In other chemical respects the gelatine can be favourably spoken of, and we have before us a report from the Munich School of Photography, emphasising its suitability for emulsion and litho work. It has been found absorbent of water at 60 degrees F. to the proportion of from five to ten times its original weight, and to be well suited for the preparation of a clean working emulsion. Samples and prices of the gelatine are obtainable from the British agent, Mr. Otto Rosenstiel, 104 and 105, Cheapside, London, E.C.

Medallion Brand Photo Paste Powder. Sold by Kodak, Limited, 57-61, Clerkenwell Road, London, E.C.

The necessity for a reliable mountant for photographs is always with us, and although many workers prefer the methods of dry mounting advocated from time to time or mountants containing

very little moisture, there are always those who like a paste that can be applied in generous measure when necessary, and which can be relied upon to stick. The new introduction by Messrs. Kodak seems to meet all the requirements of a reliable mountant. It is sold in the form of a finely-ground powder, and appears to be perfectly neutral, so that its application to the most delicate photograph need not be feared. The paste is prepared from the powder in the manner made familiar to those who employ starch as a mounting medium. One ounce of the powder is worked up in a little warm water until it is of the consistency of cream. The addition of three-quarters of a pint of boiling water, accompanied by constant stirring, converts the cream into a thick, gelatinous, semi-transparent mass, which sets when cool into a thick jelly of great adhesive qualities. It is recommended to boil the whole in a saucepan when practicable instead of adding boiling water, and the thickening of the liquid occurs in exactly the same way as when starch paste is made. Messrs. Kodak state that paste made with this powder will be found to remain good and retain its adhesiveness to the last, but we have not had the sample sent to us in use a sufficient time to test its keeping powers. It is supplied in 3d. packets, and in 1 lb. boxes at 8d.

CATALOGUES AND TRADE NOTICES.

ELLIOTT AND SONS, Limited, of Barnet, announce that they have now introduced three new and distinct colours in their Barnet Carbon Tissues, which should be a valuable addition to their present series of fourteen colours. The new tissues are styled Egyptian Black, Agate Green, and No. 2 Red Chalk. Arrangements can be made with photographers in any part of the world for regular supplies of these, or any other tissues.

A VIENNA firm sends us a circular of a novelty in the shape of a method of producing backgrounds on negatives, the process permitting of their rapid removal, and being also inexpensive. Presumably particulars can be had from Fonton, Sternneckplatz 18 I, St. 22, Vienna, II.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
9.....	Woolwich Photographic Society	Outing to Old Bexley and Crayford.
9.....	Glasgow Southern Photo. Assn.	Trip to Jerviston Estate.
9.....	Manchester Amat. Photo. Soc.	Outing to Taxal.
9.....	Bowes Pk. and Dis. Ph. Soc. ...	Outing to Hampstead Heath.
11.....	Southampton Camera Club.....	"Pinhole Photography." Mr. W. R. Kay.
13.....	Southport Photo. Society.	Trip to Millers'ale and Tidesdale.
14.....	London and Prov. Photo. Assn.	Open Night.

THE winter programme of the London and Provincial Photographic Association is to hand. We note among the fixtures that Mr. A. L. Henderson will lecture on "A Fortnight in Brittany" on September 21, Mr. J. C. S. Mummery demonstrates "Gum-bichromate" on October 12, Mr. J. Burgess, one of the first pioneers in gelatine photography, and a manufacturer of emulsion in 1873, gives the "History of Gelatine Emulsion Plates" on November 2, and "A Comic History of Photography," with illustrations from "Punch," is due on November 16. Mr. C. H. Davis is the author. These are only a few of the good things, and a lecture or demonstration is down for every Thursday night until Christmas. Mr. H. C. Rapson, 13, Shaftesbury Road, Hornsey Rise, N., is the hon. secretary.

THE usual comprehensive fixture list has been prepared for the winter session of the South London Photographic Society, and the member must be very hard to please who does not think he is getting the value of his subscription from the numerous good things

provided. The winter session opened on Monday with a successful conversazione, and papers will be read at the meetings, held twice a month, until April next. Excursions are continued throughout the winter, and a series of elementary evenings have been arranged. Monthly progressive competitions are announced, and particulars of the annual exhibition to be held in March next are also given. Mr. H. Creighton Beckett is the hon. secretary, and his address is 44, Edith Road, Peckham, S.E.

THE hon. secretary of the Bowes Park and District Photographic Society has sent us their winter programme, which contains an attractive list of fixtures. Mr. Hy. C. Bird is the hon. secretary, and he will be pleased to hear from intending members. His address is 91, Whittington Road, Bowes Park, N.

Commercial & Legal Intelligence

At the Lambeth Police Court on Saturday last, Henry Andrew Spinney, a clerk, of Somerleyton Road, Brixton, was charged on remand with stealing, by means of a trick, 60 oz. of silver nitrate, value £5, the property of Messrs. John Griffin and Sons, Limited. The facts of the case were given in our last issue. The prisoner left himself in the hands of the magistrate, remarking that he would prefer not to go to the Sessions, as he had, unfortunately, been in trouble once before. The magistrate characterised the theft as an artful one, and sentenced the prisoner to four months' hard labour.

PHOTOGRAPHING on Sunday at Castleford, last week, Henry De Redder, photographer, pleaded guilty to taking the photographs of two young men at his studio in Carlton Street, on the previous Sunday. Defendant said he did not know the law. The Chairman said he must have known it was illegal, and fined him 7s. 6d., or seven days.

RE Charles Henry Burnaby Sparrow, 1, Chepstow Road, Croydon. —The statutory meeting of the creditors interested under this failure took place at the offices of the Official Receiver on Friday afternoon last. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £1,794 1s. 10d., of which £219 was due to unsecured creditors, and £1,535 to fully-secured creditors, the securities being estimated at the same amount. The assets were returned at £30 7s. 11d., thus showing a deficiency of £189 1s. 10d. The bankrupt, who is fifty-six years of age, was for four years prior to April last employed by the Photographic Art Development Company, Limited, and since June, 1903, by the Photographers' Art Paper and Requisites Company, Limited, as manager. He was also a director of the last-named company. Both companies have now gone into liquidation, and he claimed £118 from them for arrears of salary. The estate was eventually left in the hands of the Official Receiver for summary administration in the usual manner.

A HUGE CLAIM.—What was practically a claim for a quarter of a million sterling, as damages for the alleged infringement of a copyright photograph of the Marquis of Bute, was heard in the Glasgow Sheriff's Court recently. The claimant was Mr. Charles Sweet, a photographer of Rothesay, who sued the proprietors of the "Scottish Weekly Record" for £10 for every copy of the issue (estimated at 25,000) containing the picture. The proceedings were brought under the Summary Jurisdiction Act, no appeal thus being permissible against the decision given. In dismissing the action as incompetent, and finding the defendant entitled to expenses, the Sheriff said he was quite sure it was not the intention of the legislators to vest the Summary Court with a right to decide finally upon a claim nominally for £250,000, with no right of appeal.

News and Notes.

PICTURE Post-cards.—According to the French papers, an advance has been made in regard to the continental regulations for written matter on the backs of post-cards, at least as far as France, Germany, and Belgium are concerned. The new regulation is already in force, and correspondents in these countries can now make their communications on the address side of the card in the same way as we are accustomed to do in this country.

THE scheme which has been under consideration for some while, for the establishment of a Royal Academy of Arts in South Africa, has now so far advanced, says the "Globe," that a petition for a charter of incorporation is soon to be presented to the King. This petition will be signed by a very large number of the most prominent men of the colonies of British South Africa, so apparently the new Academy will receive that full measure of local support that is needed to ensure its success.

FOR a long time the police authorities of Paris have been looking for a certain thief, of whom the anthropometric department possessed six photographs taken in different positions on the occasion of previous convictions. These photographs were sent to all the towns and communes in France. A few days ago the detective department received from the police commissary of a small town the following letter:—"Sir,—I have duly received the photos of the accused persons you are seeking. I have already arrested five of them, and the sixth has been traced by my officers, who hope in a short time to capture him."

WE read in the "Yorkshire Daily Post" that Mr. Alexander Keighley, of the High Hall, Steeton, well known as an amateur photographer, was married on Saturday last, at the Parish Church, Rotherham, his bride being Miss Lily Howroyd, only daughter of the late Mr. Jos. Howroyd, Bradford.

WE learn from the "Morning Post," that the eclipse party of the British Astronomical Association, at Burgos, under the direction of Mr. C. Thwaites, M.Inst.C.E., F.R.A.S., obtained a great number of successful photographs. The travelling and housing arrangements were under the management of Mr. John H. Gear.

SIR BENJAMIN STONE'S fame as the Parliamentary photographer and the doyen of survey and record workers with the camera, has been known to the general public for some years, but they have not, nor indeed have many photographers, had the advantage of seeing the productions of this able and privileged amateur. Messrs. Cassell are about to supply this want by publishing, in fortnightly parts, a selection from the twenty thousand or so photographs which constitute Sir Benjamin's unique collection.

A DEVICE for taking photographs from the tail of a kite for war purposes, which has recently been put into practical use by the Russian Army, was invented by Mr. A. d'P. Weaver, of Montgomery, Ala. The construction and operation of the device is briefly described as follows in "The American Inventor": "In a light framework of aluminium-bronze there is suspended a photographic camera having electrically-actuated plate or film changing and shutter operating mechanisms. The camera as mounted in the frame has movement in altitude, the angle of inclination being read off a graduated quadrant. Attached to the framework, in a plane parallel to the axis of the optical system of the camera, are arms extending from either side. These arms are 10 ft. in length, and carry upon their outer ends hollow aluminium spheres 24 in. in diameter. Above the arms carrying the balls is mounted a wind vane 18 in. in width and 6 ft. long. This vane has a movement in azimuth, and can be set at various angles with the axis of the

camera. It is thus seen that there are two movements of rotation, the camera itself having a movement in altitude, and may be inclined to any angle with the horizon, while the wind vane, having a movement in azimuth, may be given any angle to the camera axis and to the sighting balls. The whole apparatus is designed to be carried into the air by means of a small balloon or box kite, and is held captive by a small electrical cable, the size of an incandescent light cord, through which, by means of a few dry cells and the necessary keys, the plate-changing and shutter-operating mechanisms are actuated by an observer on the ground. Forming part of the equipment is a small telescope, similar to a surveyor's transit, having movements in altitude and azimuth. To this telescope is attached a right-angled eye-piece or ocular having vertical cross hairs in its field."

A CORRECTION.—Mr. W. S. Davenport writes:—"Herr Friedrich Schroeder, of Brandenburg, asks me to correct the statement made in the report of the Darmstadt Congress that the duration of a flash-light explosion varies from 0.15 to 0.20 seconds. It should be 'one-fifteenth to one-twentieth of a second,' as I had intended to make it. The exact time necessary to explode ten of his patent electric flash lamps one after another was 0.175 second, which I rounded off to 0.2 second."

Correspondence.

THE HENDERSON AWARD AT THE L. AND P.

To the Editors.

Gentlemen,—Will you kindly allow me space to announce that the last day for receiving papers for the L. and P.P.A. Henderson award has been fixed for October 5 for papers read or published between July 1, 1904, and June 30, 1905. Papers should be submitted by the author, his nominee, or a member with the consent of the author, and, unless submitted by the above date, cannot be considered when the award is made. The award is £5 in cash, or gold medal, or silver or bronze medal and cash, or apparatus, whichever the winner may decide, and is for the best paper on a photo-chemical or kindred subject published during that year.

Non-members wishing to submit papers should communicate with me, stating date of reading or publication, as soon as possible.—Yours faithfully,

HERBERT C. RAPSON, Hon. Secretary.

"White Swan," Tudor Street, September 4, 1905.

THE DISPLAY OF SPECIMENS.

To the Editors.

Gentlemen,—You are constantly "girding" at photographers for their want of business tact and acumen, and rightly so. Will you allow me to call attention to one phase of it, which is amazing in its stupid indifference and carelessness? I allude to the constant display of really fine photographs in the shop windows "dumped" down, so to speak, without a single word as to the place or person represented. In the case of photographs for sale, I am certain, judging from my own experience, that many a sale is lost owing to lack of title and price. The idea would seem to be that what should interest most is the perfect "technique" displayed, as if the veriest "dolt" nowadays cannot turn out a thing perfect in "technique." The average man or woman does not care to go into

a strange shop to ask questions which, after all, owing to the price, perhaps, being a little beyond them, does not result in a purchase; and the London shopkeeper, at any rate, does not err on the side of courtesy under such circumstances—actions speaking louder than words. Perhaps now that the matter is ventilated we may hope to see an improvement.—Yours faithfully,

JOHN DE SAULLES VAUGHAN.

1, Heathcote Street, Mecklenburgh Square, London, W.C.,

September 4, 1905.

THE ACTION OF METOL AND ORTOL ON THE SKIN.

To the Editors.

Gentlemen,—Replying to your correspondent, Mr. J. Mallia, who asks for a remedy for his skin trouble, I can recommend him and anyone else troubled with skin diseases to try "Antexma." It can be had in 1s. bottles at the chemists, or from the Antexma Company, 83, Castle Road, N.W. This preparation has been a blessing to me, otherwise it is no interest of mine to advertise it.—Sincerely yours,

NICHOL ELLIOT.

7, Chapter Road, Willesden Green, N.W., September 2, 1905.

To the Editors.

Gentlemen,—I have read with interest the experiences described by your various correspondents as to the effects metol and ortol developers have on the skin. In my own case the symptoms appear to be somewhat different to those mentioned. I use a considerable amount of metol-hydroquinone developer, and have employed it extensively in making big enlargements on bromide paper. This has usually necessitated the complete immersion of my hands and wrists in the developing solution, and until recently no ill effects appeared. Of late, however, I have found the palms and fleshy parts of my hands, especially the thick parts of the hand between the base of the little finger and the wrist, harden and peel in a curious fashion. Dry blisters have appeared, and these have scaled off, leaving new skin underneath. At no time is there any irritation or itching, but simply blistering and peeling of the skin. That it is due to the immersion of my hands in the developer, I am convinced, as I find the symptoms disappear if I do no developing of this kind for a week or so, and reappear as soon as I start again. Ortol appears to have no effect whatever on my hands, but I find that the application of lanoline or other toilet cream a good plan to keep them in order for all photographic processes where it is necessary to dabble much in solutions.—Yours truly,

H. A. C. MATALL.

Woolwich, September 4.

VELOX DEMONSTRATIONS.

To the Editors.

Gentlemen,—May we ask you to kindly draw the attention of secretaries of photographic societies and camera clubs to the fact that we are prepared to send out demonstrators free of all charge to societies during the 1905-6 season, and as we are anxious to complete our programme at the earliest date, we shall esteem immediate applications.

The subject treated will be "Velox and its New Applications."

We may say that every effort will be made to make these demonstrations of an attractive and instructive nature. Some entirely new features which have developed during the last two years will be introduced, and these cannot fail to prove of great interest.—Yours faithfully,

JOHN J. GRIFFIN AND SONS, LIMITED.

20-26, Sardinia Street, Lincoln's Inn Fields, London, W.C.,

August 31, 1905.

Answers to Correspondents.

- * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.*
- * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- * *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

- F. BARNES, JUDR., 1, Ash Grove, Manchester Old Road, Heaton Chapel, near Stockport. Photograph of Thatched Cottage that formerly stood at the corner of Green Lane, Heaton Moor.
- J. H. CARTWRIGHT, 171, Orford Lane, Warrington. Photograph (Combination), Postcard of Views of St. Helens.
- W. E. SORRELL, 55, Topsfield Parade, Crouch End, N. Two Photographs of York Cottage, Sandringham. Three Photographs of the Princess of Wales and Infant Prince John. Two Photographs of the Princess of Wales, Infant Prince John, Princess Mary, Prince George, and Prince Henry. Photograph of the Lake at Sandringham. Photograph of the Princess of Wales, Princess Mary, Prince Henry, and Prince George. Photograph of the Princess of Wales, Princess Mary, Prince Henry, and the Infant Prince John.

A BUSINESS QUERY.—Like most amateur photographers who develop a good number of plates and films at a time, I have experienced certain difficulties with my apparatus. I have ideas of improving the lamp and draining rack. Can you tell me how I can benefit myself best by getting these worked out?—S. P.

If your inventions are likely to be of general value, you had better offer them to one or other of the manufacturers. You will see their advertisements in our pages and in the "Almanac."

TONING SOLUTIONS.—I want to ask a few questions through your paper but before doing so, perhaps it would interest you to know what an amateur thinks of your professional paper. I take four photographic papers every week, but always look forward to your paper coming. Perhaps it comes about from the fact that I am on the practical side of photography. I should like to know why a bath or the like goes wrong. My questions are: (1) Should the thiocarbamide bath keep clear in stock solution, and how long does it keep? (2) Can I make up a stock solution of chloroplatinite that will keep, and that I can mix to make up any formula; for instance, the two baths you give on page 544, July 14th? (3) Do all the baths given for P.O.P. and platinum toning keep well, or should they be fresh made? (I note the phosphate and formate bath must be fresh).—J. C., St. Helens.

(1) The bath can be kept for a reasonable time—a month or so. (2) Yes; potassium chloroplatinite, 15 grains, distilled

water, 2 oz. pure hydrochloric acid, 1 drop. (3) Platinum baths need not be freshly made for use, though after having once had prints toned in them they will not all keep in good condition.

J. K. M.—The lens you mention will serve your purpose for portraits, and if you arrange your groups carefully so as to make the most of the curved field of the lens, it ought to answer all your requirements.

E. A. B.—(1) The colours should be finely ground, and can be obtained ready for use from artists' colourmen, such as Messrs. Winsor and Newton, or Reeves. (2) Purified oxgall can also be obtained from the artists' colourmen, and you will find this course much better than endeavouring to make it yourself. (3) The colours will not run if care is taken. The hot roller is best. A flat iron can be used, but the results are not always so good. (4) It is possible, but is not worth the trouble, and the results cannot be so good as those made with lantern plates. We can recommend no cheaper process. Surely a penny each is not very expensive.

C. W. A.—The "Illustrator," published by the Illustrator Publishing Co., Beekman Building, New York, U.S.A.

GUM PROCESSES.—1. Will you kindly give me a formula for a gum arabic film (bichromate) for etching on metal? Any other gum that is insoluble in alcohol will do, but gelatine is useless. I have found gum arabic alone sensitised with bichromate flakes up directly it is dry, and is difficult to coat on metal, as it runs off easily. Is there any remedy? 2. Will you tell me also if it is possible to make a carbon transfer paper with gum arabic instead of gelatine for the coating, as I believe there is nothing of the kind upon the market?—H. S.

1. The best gum acacia was formerly employed in half-tone work for sensitising the metal plates, but it is not so satisfactory as fish-glue. With gum, it was usual to use chromic acid. We should think you had better try one of the fish-glue formulae, of which there are many at present, such as the following:—Water, 16 oz.; fish-glue, 8 oz.; ammonium bichromate, 350 grains; citrate of iron and ammonia, 50 grains. 2. There is no method, so far as we are aware, of rendering a coating of gum arabic suitable for transfer paper for the carbon process. Besides, it would be more expensive.

DUNCE.—Full particulars concerning apparatus of this kind will be supplied by Jonathan Fallowfield, Charing Cross Road, London, W.C. The prices, as listed by him, range from 12s. 6d. to £10 10s. The latter price includes twenty-five lenses. Sufficient lights should be used to illuminate the copy evenly, and if only a few are used—say two—it becomes merely a question of prolonging the exposure. A few trials will soon decide this.

T. E. GUBBINS.—Your best plan is to use a strong black aniline dye, such as Judson's. The application of a couple of coats of this will be sufficient.

A. POWELL.—Are you quite sure you have the proportions right? An excess of oil would cause the effect you mention. This excess of oil in the total bulk would also arise if the varnish has been exposed to the air for any time. The spirit evaporates, and the proportions of the formula become altered.

MENDING PAPIER MACHE.—I have a large paper-maché tray, in very good condition except the corners, which have all the black enamel worn off, showing two or three thicknesses of cardboard. Could you tell me what to do with it?—E. S. B.

You will be able to effect a satisfactory repair with Prout's Elastic glue. This is sold in sticks, and is applied after the manner of sealing-wax. The mended portions can be smoothed down with a hot iron. It is quite waterproof.

RETOUCHING (Reply to E. C. P.).—Your touch is soft and natural, and the likeness for commercial purposes is pleasing, although, personally, we prefer the characteristic expression of the unretouched to the smiling alteration made by your pencilling—but this is merely a matter of individual taste. Balance the shadows under the eyes to better effect, and see that the shadow side of face is not in too violent contrast with the light side. The modelling of the nose is rather ragged, and, this being the most prominent feature, should always receive the most careful attention.

SELLING JEWELLERY.—Would you kindly inform me whether there is a weight limit in supplying hall-marked gold pendants for miniature photos without a gold licence; if so, would you kindly state the weight?—F. O. S.

No licence is required if the article sold is under 2 dwt. Above this weight a licence is required, and costs as follows:—Above 2 dwt. and under 2 oz. gold, £2 6s.; above 5 dwt. and under 30 oz. silver, £2 6s.; above 2 oz. gold and 30 oz. silver in one article, £5 15s. We are informed by Messrs. Dorrett and Martin, who make this business a special line, that all the gold goods in their list are under the 2 dwt.

PRINTING POST-CARDS.—We are in want of a rapid post-card machine for printing cards in batches of 100 to 1,000 from a negative in bromide paper. Can you let us have any particulars and price of any such machine on the market for turning the post-cards out quickly? Or can you inform us where such machines are made?—F. E. W.

If you will turn to page 570 of our issue of August 25 you will find the addresses of several makers of machines.

CUTTING POST-CARDS.—Will you be good enough to say where to get a machine for cutting cards into the official sizes and C.D.V. and cab. sizes? Shall have a large quantity to do, and I expect, also gelatine and chloride sheets to cut.—H. M. ALLEN.

Card-cutting machines, of all sizes, are regular stock articles by all the large dealers, such as Marion's, Fallowfield's, Houghton's, and others.

J. W. H. B.—1. As we presume you only intend to work with a north light it is quite immaterial how near the studio is to the outbuildings, as you will not need light from that side. 2. We should have a ridge roof, but the ridge out of the centre—say a couple of feet nearer the south side than the north. 3. About 5 ft., or 5 ft. 6 in., at either end solid, the rest glass, side and roof. 4. Dark blue or light green will be suitable. 5. No, as you have so much space at your disposal; 20 ft. is too short for convenient working, more particularly in taking groups and full-length figures. We should advise you to make it quite 25 or 26 ft. long, and a foot or two wider. You will then have an ideal studio, with an ideal aspect.

PLATINUM RESIDUES.—I should be much obliged if you would inform me whether there is platinum of any value as regards refining purposes to be extracted from the platinotype developing bath. About thirty sheets (26 by 20) weekly go through the bath, which is never thrown away, but added to as occasion requires. If it contains platinum in paying quantities, I

should be glad to know the best process for precipitating same.—**PLATINA.**

With your consumption of paper we should say that residue would be well worth saving. The platinum may be thrown down by boiling the solution in an enamelled vessel after a little sulphate of iron solution, acidified with sulphuric acid, has been added to it.

REFLEX.—If you wish to employ the single components of your camera and rely on getting satisfactory sharpness with the subject you mention, a reflex camera will undoubtedly be the right type of instrument to get. They do not all suffer from the fault you mention. The best all-round type of camera for the work, provided you are content always to use the lens in its complete form, is the folding focal-plane hand-camera, which there are several good and reliable examples on the market. These have direct-vision view-finders. The camera especially mentioned will be found rather bulky in use in comparison with the type recommended. The changing box is very good, but is apt to cause pinholes by the internal friction working up dust. Dark slides will usually be found more reliable for the work.

SCRIBBLER.—The Tress Company, 205, Oxford Street, W.

A. S. A.—We cannot give the address.

PROFESSIONAL Photography at the R.P.S. Exhibition.—From information to hand, we understand that professional photography will be represented on a larger scale at this year's R.P.S. show at the New Gallery than has been the case for many years. We are pleased to know that professional photographers are waking up to the fact that publicity of this sort carries with it advantages that have not been fully appreciated in the past. Their work is brought to the notice of a large section of the public that they probably could not easily reach otherwise, and the very fact that the photographs of many professionals are shown together must undoubtedly have a good effect in increasing the standard of the work as a whole.

Boom in Photographic Fruit.—According to the morning papers a boom in "King's portrait" apples is anticipated this year. This is the result of the success last season of the one parcel of apples imprinted with photographs of the King. This year, accordingly, it is thought probable that several specimens of portrait fruit will be put on the market by the English fruit growers. The French growers are following suit, and it is possible that several specimens of fruit containing *entente cordiale* photographs will be sent to Covent Garden. Portrait fruit may also come from America and Canada, as several of the largest growers in those countries obtained last year special information from an English expert on the use of photographic films on apples.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

PRELIMINARY ANNOUNCEMENT.

THE forty-fifth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,612 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued or two such unique facts be recorded. The edition for 1906 will also consist of 25,000 copies.

The lines followed in the previous editions of the ALMANAC will be maintained, in general, but in a number of particulars the arrangement of the volume for 1906 will be modified to make it more than ever the book of universal photographic reference. As in the past, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1906 will appeal to photographers all over the world as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded, and wherever practicable new features of an informative nature will be added.

* IMPORTANT NOTICE.—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1st, as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

EX CATHEDRA.

Pinatype.

Readers of the "British Journal of Photography," will remember in our issue of October 14, 1904, a description of Dr. König's new process for colour-printing on paper by means of the leuco-bases of dyes. Owing to the instability of the dyes which it was necessary to use in that method, the process has now been withdrawn, and replaced by a new one, which has been called "Pinatype," and which will appear on the market very shortly. This new method depends on the property possessed by unhardened gelatine of absorbing dyes with greater ease than hardened gelatine. If from a set of three-colour negatives three transparencies be made, and then, under these transparencies, plates coated with bichromated gelatine be exposed, we shall, after washing, have a result in which high lights in the original will consist of hardened gelatine and shadows of unhardened. Consequently, if we place this in a dye bath we shall obtain a positive transparency. Now, if on this transparency we place a piece of the specially-prepared transfer paper the dye will be slowly transferred from the gelatine to the paper. The process is worked as follows:—The three positives are prepared from the negatives and then from these positives three printing plates are prepared with bichromated gelatine, and dyed, the dyeing, in the case of the pink and blue plates, taking at the first time fifteen minutes; for the yellow plate, thirty minutes. The plates are then rinsed. The transfer paper is then soaked in water, and squeegeed on to the blue-printing plate. In about ten minutes the blue dye will be transferred to the paper. The print is then removed to the red-printing plate in register, and the process repeated. The yellow plate only differs in that it requires about thirty minutes for transference. The print is then hardened, washed, and dried, while the printing plates dye up again in the dye-baths in about ten minutes, and can be used continually, so that many prints can be obtained. The results shown are excellent, and the process is cheap. It is probable that Mr. Scholl, who has been assisting Dr. König, will be in England shortly to demonstrate the process on behalf of Messrs. Meister, Lucius, and Bruning.

One-plate Colour Photography.

In view of the fact that there has been found in England some considerable difficulty in working the Smith three-colour plate, it may be of interest to note that a representative of THE BRITISH JOURNAL OF PHOTOGRAPHY was enabled recently at Zurich to see the preparation of the plate for development by Dr. Smith, as well as to examine some satisfactory results which have been obtained. A new frame has been devised by Herr

Szczepanik by which the separation of the three different films has been greatly facilitated. A plate is placed in the rebate in the centre of the frame, and covered with a sheet of black paper carried on a small sliding bar, which is so arranged that the extreme corner of the plate is left uncovered. So far no light can be used, but for the next operation even candle-light may be employed. The two top films are cut through with a sharp knife, and gently lifted free of the bottom film. Next, in a dim red light, the top films and the black paper are pulled back together, and stripped off evenly. These two films will consist of the top and the second gelatine films, giving two final plates with a collodion film between them. Hence, provided a developer can penetrate to both sides—the film being held vertically in a clip—these two films can be developed at once, and stripped apart when dry. The bottom film remaining on the plate has a layer of collodion on top of it, which must be removed before development by soaking the plate for five minutes in methyl alcohol (not methylated spirit). The results obtained are encouraging, and greater success should follow when the collodion films are coated by a new machine now in preparation, not by hand, as is done at the present time.

* * *

Post-card Refinements. The manufacturers and vendors of post-cards, among which we include the sensitive photographic cards, have need to keep a strict surveillance over the size of the card, for, apparently, the Post Office authorities administer the regulation as to maximum size without any tendency to laxity. A case in which a number of postcards was surcharged because they exceeded the official dimensions of $3\frac{1}{2}$ by $5\frac{1}{2}$ inches transpired recently, and, as our contemporary the "Chemist and Druggist" ascertains, the excess of length in one case did not amount to more than one-fortieth of an inch. We should have thought a rather wider margin would have been permissible; but the Post Office evidently desires to keep strictly to its regulations. In any case, the department cannot be accused of wishing to discourage the circulation of the picture postcard, for its policy of the last year or two has embodied measures to which in a large degree the fecundity of the postcard cult is attributable.

* * *

The R.P.S. Exhibition. There appears to be no doubt that this year's R.P.S. exhibition at the New Gallery will be a remarkably good one. Over two thousand five hundred exhibits have been entered in the pictorial and technical sections as against two thousand last year, and we understand the selection has been conducted on very drastic lines. This is a great victory for the "anti-pot-hunter" faction if they care to regard it in this light, as it is a significant fact that, in spite of the warnings regarding the probable loss to the society if the R.P.S. medal was withdrawn, the standard of the work submitted to the Selecting Committee is, we understand, of higher quality this year than in any previous exhibition. Nevertheless, we are inclined to think that the question of the medal makes very little difference one way or the other to the number of entries, and regard this influx of extra work as merely one of the natural consequences of the very systematic and wholesale distribution of notices and entry forms that has been going on for some months past. At the same time it cannot be denied that the absolute withdrawal of the R.P.S. medal, an award to be regarded as a thing apart, not to be compared with the awards in any other sort or kind of exhibi-

tion or competition, is somewhat in the nature of killing a degree that had a distinct value to its possessors, and place of its own in the photographic world that nothing else can fill.

* * *

Professionals at the Royal. As indicated in a brief note last week professional photography will find a very prominent place in this year's exhibition at the New Gallery, apart from that entered in the pictorial section. At first this may appear curious, in view of the fact that no specific section for professional work was set apart in the prospectus. In previous years this section has usually been specially denominated, but as a rule received very scant support. This year, therefore, it appears that the section was deliberately omitted but it was decided to extend the trade exhibits usually confined to the Fountain Court, to the North and South Rooms, and to separately canvass the leading professionals of the country to take spaces on the walls of these rooms. The success of this course is evidenced when we understand that professionals of the calibre of Crooke Downey, Hollyer, Histed, Lambert Weston, and many others will be extensively represented; while, as usual, most of the leading material and apparatus makers will also be in evidence. We do not think, however, that any harm would have been done in retaining in the prospectus the special section for professional work, as, until we learn recently that the professional photographers were being circularised separately, we were under the impression that the section had been abolished, and so informed possible exhibitors.

* * *

Sunday Photography. A photographer at Castleford has recently been fined 7s. 6d. with the alternative of seven days' imprisonment, for taking two portraits on the Sunday. The defendant said he did not know the law, as well he might not, for the Act under which he was convicted is one that was passed in the time of Charles II. and, as it has never been repealed, it is still on the Statute Book, though now very seldom enforced. The chairman of the local bench told the defendant that he ought to know that the working of his ordinary trade on the Sunday was illegal. We should have thought that this antiquated kind of "bumblodrom" was confined solely to a small Buckinghamshire town, but it is clear that it exists in Castleford as well. If this antiquated and practically obsolete law were put into force against every photographer, or other tradesman, who follows his calling on the Sabbath there would be a pretty long list of convictions every week. It is somewhat consoling, however, that the most the magistrates, who have to deal with the cases, can do is to fine the defendants the modest sum of 7s. 6d. which, we think, includes the costs, with the alternative of seven days imprisonment. Not a few photographers who trade on Sundays put through more business on that day than they do all the other days of the week put together, so that this modest fine would not be much of a deterrent to them. At the present time it would be rash to speculate on the amount of amateur photography that is done on the Sabbath.

* * *

Balloon Photography Redivivus. It is extraordinary how photographic inventions that have become forgotten are re-invented. On page 718 of our last issue, is a description of a photographic appliance which has been put into practice by the Russian Army for taking photographs from a kite or captive balloon, for which a claim to novelty is put forward.

now, as a matter of fact, the late Mr. W. B. Woodbury, nearly thirty years ago, invented for the same purpose an apparatus, which seems to be practically the same thing. Mr. Woodbury took out a patent for his invention (No. 547, 1877) and we may make here a quotation from the specification as given in the official abridgments:—"In place of the car of the balloon there is a wooden box open below, to one side of which the rope by which the balloon is held is fastened. From the opposite side projects a light sail or rudder which, by the action of the wind, prevents the balloon turning round. Suspended by a pivot at the top side of the box is the camera, which thus hangs vertically. The lens points downwards, and above are two rollers carrying strips of flexible sensitive tissue. The lens has a rotary instantaneous shutter working by an diaphragm or other spring, but an oscillating shutter may be used. The apparatus is worked by an electric current, for which purpose three wires are entwined with the rope by which the balloon is held—one wire is for the return current; one wire is connected with an electro magnet and with this, clockwork, so that by completing or interrupting the circuit the sensitive tissue is rolled from one roller to the other to expose a fresh surface; a current along the third wire by means of an electric magnet, releases the shutter and gives the exposure. Thus by alternating the current, a series of photographs may be obtained." Those who read, last week, the description of the apparatus employed by the Russian Army and compare it with the above of Mr. Woodbury, will see a strong family likeness between the two.

* * *

Infringement of Copyright.

We have frequently dwelt in these columns upon the attitude of photographers who do not consider certain of their pictures worth the registration fee of the copyright, or neglect to register them, and then the moment they find that someone has reproduced them, discover they have suffered a very considerable injury. In other cases where the registration has been duly effected, and the picture has been reproduced, they often think they are entitled to recover an extraordinary sum by way of penalties and damages. A case in point was briefly reported in our last issue, where a photographer of Rothesay had taken in the Glasgow Sheriff's Court, the proprietors of a Scottish weekly paper for damages for the infringement of his copyright in a portrait of the Marquis of Bute. The claim by the plaintiff cannot be characterised as being a very modest one, as it was for £10 for every copy of the paper issued, and as it was estimated that the edition amounted to 25,000 copies, the claim represents a sum of just a quarter of a million sterling. There are many photographers who would gladly see any one or the whole of their copyrights infringed for a thousandth part of this sum per picture. At the trial the case broke down really at a point of law. It was brought under the Summary Jurisdiction Act, and thus no appeal was permissible against the decision given, whatever it might be. In dismissing the action as incompetent, the Sheriff remarked that he was quite sure it was not intended by the legislators to vest the Summary Court with a right to decide finally upon a claim nominally for £250,000 with a right to appeal. He, therefore, dismissed the action and allowed the defendant his costs.

* * *

Huge Claim. Now it is quite possible that if the sum claimed has been a reasonable one, the court would have dealt with it in the usual course and the plaintiffs would have recovered something by way of

damages. According to the Copyright Act, the maximum penalty for each copy reproduced is ten pounds, and that is none too much in the case of a painting, of which only one or two copies are made, but in respect of a photograph, reproduced in an illustrated paper with a circulation of fifty or perhaps a hundred thousand copies, such a penalty becomes absurd. In a case tried in London, some time ago, the Court came to the conclusion that, as the Act specified a sum of money for each copy, some coin of the realm must be awarded, and consequently a farthing was given. But, even at this sum, the total was so large that the judgment was appealed against, and it was ruled in the higher court that the penalties could be assessed at a lump sum, and not necessarily as one for each print. The minimum fee fixed by the Photographers' Copyright Union, and the P.P.A., for the reproduction of a copyright picture is half a guinea. That is the minimum fee but, of course, the holder of the copyright is not bound to charge no more than that sum; he can charge whatever he likes, or withhold the right to reproduce altogether if he chooses. Almost any photographer is willing to grant the right of reproduction of ordinary subjects for half a guinea or a guinea, but if the picture is copied without let or leave, then he is quite justified in suing for penalties or damages, and we are always gratified when we see that substantial sums have been recovered, as the incident is a lesson to those who would appropriate other people's property. But in bringing an action, it is very unwise to claim such an exorbitant sum as that in the above case. In a report of it just to hand, it appears that the plaintiff had previously sold, to another paper, the right to reproduce the Marquis of Bute's portrait for half a guinea, and it was this reproduction that the defendant had copied. The author then sues for damages to the amount of no less than a quarter of a million pounds!

THREE-COLOUR PORTRAITURE FROM THE COMMERCIAL STANDPOINT.

THROUGHOUT every era of the history of photography the aspirations of its exponents have been towards the representation of objects in the colours of Nature. Even in the first delirium of enthusiasm with which the discovery of Daguerreotype was received by the French capital, that note did not lack expression. It was rumoured that M. Daguerre had very little to do in order to give the last touch to his process by which it would attain perfection. That anticipation of fact has been with photography ever since. Assurances have been often unfulfilled, but now we stand not far outside the threshold of what practical photographers will regard as practical colour photography. Signs are not wanting that the conviction of the commercial value of a process of colour photography, which might be employed in portraiture has steadily strengthened, and that the outlook on current advances is keener now than ever it has been before. The printing press has been in advance of the photographer in creating a taste for colour among all sections of the community, and the monochromatic products of the photographic process are made to look pale beside the gorgeous hues of lithography and three-colour half-tone. Yet there are signs also that the photographer is on the watch to provide what the public wants, as witness the coloured miniature which has become a fixture in the price-list, and has proved highly profitable to many a business. The coloured or tinted print, too, has had its share of attention, though not with any greater success than, in the majority of cases, its qualities entitled it to. But to what extent has there

been any actual movement towards pressing processes of colour photography into the service of the studio as a money-winner? It cannot be said that any process can boast at present of any appreciable commercial application. It is within our knowledge that more than one method of colour photography for which great things have been claimed have been seriously examined by leading photographers with a view to putting them into practice. But nothing came of them; the processes could not respond to the demands made upon them. Until the announcement some weeks ago that a studio had been opened in Berlin solely for portraiture by a three-colour process, we could not have named any establishment in which such work was carried on on a commercial scale. A well-known German professional, Herr Perschied, has been associated with a modified three-colour method, but we are not aware that he has actually put it in operation in the regular way of business, though presumably the process is technically a success. A more recent example of colour photography in the professional's business has come before us in the shape of a considerable edition of portraits of the King, executed by Messrs. W. and D. Downey for the Indian Government. In this case a large coloured portrait had been prepared from the original photograph of his Majesty, and over 500 smaller reproductions were supplied in the form of three-colour half-tone process prints. This form of three-colour print is not one which can often be applied in commercial photography, nor is it one which would, in the majority of instances, prove readily saleable. But in the case of his Majesty's portrait the final result of the framed print is very handsome. The execution of the order is certainly notable as showing the demand which exists in the highest circles for trichromatic prints in preference to photographs which, in everything but the possession of colour, are immeasurably their superiors. Assuming this demand for the coloured picture to be, as we believe it is, common to all classes of society, we may ask the questions. Is it technically possible and commercially possible to supply the demand?

Technical possibility hinges chiefly on the minimum to which the exposures necessary for the making of the three negatives can be reduced. Commercial possibility depends chiefly on the cheapness with which the composite three-colour prints can be produced. To take the negatives first, we believe it can be claimed for the modern orthochromatic plates, or for plates sensitised with the more recent dye sensitizers, that exposures for all three negatives, under favourable conditions of light, will not exceed a time which would be considered impossible by a photographer of adult sitters. Comparing three-exposure with one-exposure cameras for three-colour work, the balance of practical advantage would seem to lie with the former, for the latter are costly, more difficult of adjustment, and introduce extra filters. With a one-lens camera, in which the three exposures are made successively, the whole operations need not occupy more than a few seconds, presuming, as we have already said, the very best studio conditions. The relation of the three exposures is even more important than the correct exposure as a whole, and for this reason an accurate shutter which will automatically give, say, 2, 1, and $\frac{1}{2}$ seconds for the three screens, or can be set for other ratios as the filters may require, is a most advisable method of exposure. The apparatus, therefore, for direct three-colour negative-making is not unduly elaborate nor excessively costly.

Turning to the commercial possibility of the process, the facts for the guidance of the photographer are more difficult of quotation. In the case of large editions the negatives can be turned over to a printer and plate-maker in half-tone or collotype, and proofs ordered to the number

required, but that is a course which can be followed in few cases, and is practically useless to photographers whose order from a set of negatives cannot be expected to run to more than a dozen or two. The only practicable method for them is the triple-pigment print, the suggestion of which will perhaps be received with little enthusiasm by those who have listened to the accounts of difficulties from workers of that process. Such prints, it is surmised, must necessarily be producible only at a price which will be prohibitive for commercial work. We are not convinced of the truth of this argument. The materials of the three-colour pigment prints are cheap enough; the cost is in the labour, and estimates of that cost are made regardless of the fact that no systematic use is made of the process. Before the process can be judged commercially possible or impossible, it is necessary to discover what form of labour can be employed to print and make the pigment trichromes. It was stated some time ago that the making of three-colour prints was work requiring the patience of feminine hands for its proper performance. We would not assume that it is to be left to female labour to bring colour-photography within commercial limits, but it may be pointed out that the important question of the systematic printing of trichromes on paper requires to be worked out in figures. As things are at present, the difficulty and uncertainty of the process become magnified from the fact that the most expert of those who work the process cannot claim to be more than beginners, and that the expense of the method at present simply represents the price of experience learnt by failure.

These considerations and others affecting the commercial status of the three-colour process deserve the attention of the professional. At present the claims of the process require confirmation in practice, but we may anticipate that before very long the tri-colour method will venture upon the arena of actual commercial application. Ten years ago, when the direct-colour transparencies of Mr. Ives were prominently before the photographic world, the comment was: "Yes, this is all very well, but we want prints on paper." That request is now very near being granted. What use will be made of the new powers?

THE T.P. COMPETITION.—The Thornton-Pickard Manufacturing Company have asked us to draw the attention of our readers to the fact that their prize competition, in which £100 in cash is offered as prizes, closes on October 1. Prospectus and entry form are sent post free to all applicants.

TWO SIDES.—Photographers declaim against the newspapers, and the papers have good cause to complain of the photographers, observes the "Evening Standard and St. James's Gazette," in commenting on the claim for £250,000 recently made by a Glasgow photographer. "An instance from one's personal knowledge: Copies of a certain photograph were bought, with right of reproduction by two London firms, both of whom published. Then from the clouds there descended a syndicate saying that it had previously bought the copyright of that photograph, and must have damages and a royalty on every paper sold containing their property. One of the two firms, intolerant of a fight, paid up at once in three figures. The other, having less money and more time, looked into the bona fides of the syndicate, and to do so went up to Stationers' Hall. There, right enough, was the registration of the copyright. But—here comes the rub—that photograph had not been registered until days after it had been published in London. "You do your worst," said the little firm, "we won't pay a farthing." And they did not; they had paid already, paid the man who first had the right to sell. That syndicate disappeared as rapidly as it had materialised."

THE NATURALIST PHOTOGRAPHER.

DURING the last few years considerable interest has been awakened in natural history photography, and it is now steadily gaining votaries amongst amateur photographers. The importance of this most fascinating and altogether delightful branch of photography cannot be over-estimated, affording, as it does, a ready means of keeping a true and faithful record of the beauties and wonders of Nature. What would not dear old Gilbert White have given to have possessed this means of picturing the fauna and flora of his beloved Selborne?

Nearly every year, unfortunately, still sees the extinction of some species of bird, beast, fish, reptile, insect, or plant, and it is a duty the naturalist photographer owes to posterity to obtain through the agency of his camera, a lasting and truthful portrait gallery of these fast-vanishing forms of life. I consider he has also another and even a higher mission; for by means of the exhibition of good photographs of wild nature, showing how these creatures and plants lead their daily life in their natural environment, he is doing something to educate and to attract the attention of a thoughtless and ignorant public to that disgraceful and wanton slaughter of the innocent denizens of the wild, which is carried on, year after year, with barbaric cruelty, to satisfy the demands of senseless fashion.

Natural history photography is, without doubt, one of the most interesting and charming branches of photography that anyone can take up as a hobby and pastime. All the year round there is always something to be done, and if one could live for a hundred years there would still be subjects awaiting one's camera. To be successful as a naturalist photographer, however, and to produce pictures really worth showing and keeping, the would-be worker must be endowed with a real and deep love for Nature; he must always have an endless stock of patience at his command, and must be determined, resourceful, quick to seize the fleeting opportunity, and possess an insatiable thirst for knowledge and personal investigation into the wonders of Nature. Without patience nothing

can be done, and the naturalist photographer must be prepared to look upon his failures as useful object-lessons that are really going to help him in the end to success. Careful consideration of each failure, so as to determine why it was a failure, will do much towards the rapid improvement and quality of the work accomplished.

Start with simple subjects, and work steadily upwards. Study your subject carefully and thoroughly, trying to learn something of its nature, characteristic appearance, and environment, before attempting to photograph it; then you will obtain a picture that is at once a pleasure to look upon and a truthful record of your subject, and not a mere chemical sketch, more or less libellous in character.

Elaborate apparatus is by no means necessary for Nature work, and useful additions can always from time to time be made to the outfit as circumstances demand and permit. The mistake most commonly made by the average tyro is in attempting too much, having a shot at anything and everything that comes along. Such proceedings may result in a very large number of negatives by the end of the season, the majority of which, however, will probably be of comparatively little real interest or scientific value. Far more satisfactory will be the results obtained if the beginner will devote his attention and efforts to one particular subject, species of bird, beast, insect, or plant, and work steadily at that until he has acquired a thorough knowledge of it. Subjects are always near at hand; for instance, there is a lot of useful, interesting, and charming photographic work to be done with our common domestic pets—their facial expressions, and characteristic pose under certain conditions, which often reveal an hereditary trait (handed down through a long ancestry from their wild forefathers) of which it is well worth while to obtain a photographic record. Know your apparatus, your plates, and developing; be patient, watchful, determined, and you will succeed.

F. MARTIN DUNCAN.

PHOTOGRAPHIC SOCIETIES AND EXHIBITIONS.

SOME NOTES ON THEIR PRESENT POSITION AND MANAGEMENT.

II.

Different Types of Societies.

PHOTOGRAPHIC societies may be divided into three classes: Those that exist for pleasure, those that exist for business, and those in which both business and pleasure find their proper places at proper seasons. The first type is, unfortunately for photography, in the majority to-day, and useful though they may be in bringing together a number of people with a hobby common to all, their utility does not generally rise beyond that of an ordinary social club. Photography—the very reason of their being—is regarded merely as a convenient excuse, when one is needed, for the weekly or monthly social meeting, but seldom is an effort made, concerted or individually to do anything for its advancement. One or two members, including the secretary, who is usually the real executive, may make efforts to improve the outlook by the aid of imported lectures and demonstrations, but they are apt to fall flat and raise no discussion, and so the society drifts on in a state of stagnation. The same round of officers appear year after year by simply ringing the changes on the offices they fill. Strange to say, such societies are frequently better equipped and possessed of a larger income than many other associations of a similar kind that are really awake and alive to the necessities of their

existence in the photographic world. A complete change of officers is the only remedy that is likely to effect reformation in moribund institutions of this kind, but the necessary "strong man" to undertake the work of reconstruction is not always forthcoming.

Business, not Pleasure.

The very antithesis of this type is the society that is keenly alive to its obligations to photography generally, and has no place for social amenities. The members meet simply to discuss the business of the evening, and when that is over they promptly disperse. The serious side of photography is the very soul of this type of society, and the advancement of its affairs is its occupation. The meetings are characterised by formality and seriousness. Attention to the business at hand concerns it during the entire course of the meetings. Smoking, drinking, and other detractions are banned, and ladies are usually to be found as working members in these societies. The membership is frequently small, but the lecturer who haps on a society of this type has usually a stirring experience. His every word is devoured, and formulæ are jotted down in note-books. His bad time comes after the lecture, as every statement he has advanced is challenged in unexpected quarters; but he is on

his mettle, and the evening is usually a fairly profitable one for all concerned. The lecturer, however, meets with little attention of a convivial nature on visits of this sort, as the question of entertainment never appears to trouble these very business-like societies. They are as rare as the other type is common, and they frequently extinguish themselves by their own over-vitality. The members find out too soon that they know, or think they know, everything, and the feeling of jealousy—fatal to sustained healthy competition—alienates them from the interchange of ideas with their fellow members at the meetings of the society.

The Happy Mean.

It is to the class of photographic societies combining, to a certain extent, the best attributes of these two types that we must look in the future for the production of the best workers. Both pictorial and technical, and the executive of all societies should look to it that they emulate this type. Of the four hundred or more societies at present existent in the United Kingdom, fully one-third can be reckoned as being of this class, and when one considers the enormous increase in the number of societies during the past five or six years, this is matter for congratulation. These societies contain good workers, and the social element is not forgotten. The officials are the right sort of men to keep things moving, and in many cases the lack of interest that arises is not due so much to lack of energy on the part of the workers as to lack of "the new blood" referred to in the previous article.

Environment.

Apart from these leading characteristics of photographic societies, there is no doubt that the environment of each society affects its general tone in a marked degree, and it will more often than not be found that the society which meets in a hired room at a tavern or coffee-house once a week for a few hours is much more alive to its responsibilities than the society with its permanent quarters, library, dark-room, and other luxuries. This latter is apt to degenerate into the type that exists for its own pleasure alone, and, although there are notable exceptions, it frequently happens that the interest taken in the work of the society and the amount of keenness displayed is in direct inverse ratio to the amount of the annual subscription.

The Executive.

The constitution of the executive is usually at the bottom of the failure of many societies to "go ahead." As mentioned previously, practically the whole of the active work of the society falls on the shoulders of the honorary secretary, who probably would not have more to do if he were the paid official of a public body. The remainder of the committee usually consists of gentlemen who are prone to advise and criticise, but their advice is usually impracticable and their criticisms absurd. Some societies are blessed with a real working committee, and the secretary has more time to devote to the furtherance of the society's work.

The President.

The ideal executive of a photographic society should consist of a president or chairman, who, in addition to being the figurehead of the organisation, should be prepared to lead discussions and be capable of making a good speech. Upon the tactfulness of the chairman depends in a large measure the easy running of the meetings. The secretary may make the very best arrangements for the success of a lecturer's visit or for a big "open" night, but the actual finishing touch to make or mar the proceedings depends on the personality of the chairman. Awkward questions may be asked by a not too tactful member, accidents will occur in which a lecturer may not appear to advantage, points have to be made clear for the instruction of visitors on opening days of exhibitions, and

wrangles will take place at committee meetings. All these and many other situations are of frequent occurrence, and it usually falls to the lot of the unfortunate secretary to clear the path again. Let the president or chairman, therefore, be the right man to deal with them, and the members should bear in mind at the annual election that, given a capable and willing president and secretary, more headway will be made than if matters are left in the hands of a merely ornamental committee and the secretary.

The Reporter

One other official who is of vital use to the well-being of the society is often conspicuous by his absence from the list of officials. This is the reporter. The scope and position of this officer are not fully recognised in many societies, and his work is undertaken by the secretary. The duties of the reporter are, in a word, to make notes of the proceedings and supply them in the shape of interesting reports to the photographic and local papers. The secretary should attend to the minutes of the society, but he may draw on the reporter's notes for certain information. The supply of readable reports to the photographic Press keeps the position and activity of the society before the photographic world as nothing else can do, and the full benefit of this publicity is made obvious at exhibition time. A series of notices concerning the work of a photographic society published at frequent intervals in the columns of a paper like *THE BRITISH JOURNAL OF PHOTOGRAPHY* will do much more to add to the number of entries and quality of the work than the dispatch of unlimited circulars announcing the exhibition, just before the event. In other words, the society is being advertised by means of these reports, and its future prosperity and power to attract useful members depend to a great extent upon the persistency of this advertising. The publication of the reports in the local papers has an effect that produces a rapid return in the shape of awakened local interest in the doings of the society, and also brings the society to the notice of everyone interested in photography in the locality. It will be seen, therefore, that the preparation of reports of societies' proceedings has an important bearing on the prosperity of the society, and, apart from this, a point that is too frequently overlooked is also to be considered. A certain amount of return in the shape of all possible publicity is due to the lecturer, who more often than not has put himself to considerable trouble to prepare his paper. The secretary, in the absence of a duly qualified reporter, finds time to scribble a brief note only of the proceedings, in which frequently the names of members present, votes of thanks, and the bare name of the lecturer and his subject figure as the chief points of interest. The vital points of the lecture are overlooked, and not only is the lecturer dissatisfied, but the editor to whom it is submitted cuts it down still further to a line or two, or omits it altogether. The duties of reporter are not difficult, and therefore it should be an easy matter to find a member willing to undertake this necessary task and relieve the secretary of at least one duty during the meetings. Usually the secretary, in addition to attending to the usual secretarial duties of correspondence, arranging the programme, sending out notices, etc., and writing up the minutes, has to receive the lecturer and see to his comfort, be in attendance on him during the evening, and more often than not has to operate the lantern. To ask him to make a full report of the meeting for the current papers in addition is in most instances too much to expect; which brings us to the question of lanternist, librarian, and curator.

The Lanternist.

In every big society with rooms of its own, or even those societies who rent a room for regular meetings at stated times, the optical lantern and the accumulation of photographic

papers and books call for special attention that should only be given by officials specially appointed for the purpose. The lantern, especially if limelight is used, requires a lanternist who not only thoroughly understands the working of the jets and the regulation of the gas bottles, but should also have vested in him full powers to see to the purchase of new limes and other necessities, and to check and keep account of the expenditure of gas. The presence of a capable lanternist is always a comfort, not only to the members of the society, but to the lecturer, who more than anyone fully appreciates the value of a man who can project his slides promptly and satisfactorily, and at the same time show them to best advantage by making the most of the light. The lanternist, too, should, in addition to the knowledge of his apparatus, be possessed of a certain amount of coolness—that is, be prepared to meet all emergencies in the way of accidents, such as the bursting of rubber tubes, gas giving out, limes breaking, slides inserted upside down, etc. Lanterns in which the illuminant is other than limelight do not call for quite so much attention, and are decidedly in the minority among photographic societies. The oil lantern scarcely ever appears, incandescent gas or acetylene are never satisfactory owing to the low power of the light if a large disc is wanted. Acetylene is certainly better than gas, but calls for just as much attention, and probably more care, than the oxy-hydrogen light. The "Nernst" light and the electric arc are now frequently employed, and, although a certain amount of adjustment is always necessary, their use is comparatively simple.

The Librarian and Curator.

The librarian may also be the curator, and in most societies where this official finds a place he usually combines the duties of attending to the club literature and books, etc., and taking care of all club property in the way of apparatus, slides, dark-room materials, etc. Stock-taking should occur annually or oftener, and an account of the society's possessions and dilapidations should be presented at the annual meeting. The function of the librarian and curator is to keep all the property under his charge in readiness for immediate use by the members at any time, and to lend them out when required. By thus keeping check on all the belongings of the society a much smoother course is possible than when books and apparatus are scattered about for everybody's use without question or record. One or two other officials should also be appointed in every well-regulated society of any size. These, for the sake of convenience, can be called "stewards." Their duties should be to attend to the arrangements of the lecture room on meeting nights and see that everything is in its proper place for the reception of the lecturer, who may require assistance during the course of a demonstration, such as dark-room appliances, black-board, etc. The stewards should also make a list of the members for the use of the secretary and the reporter. The importance of the work of this latter official has been only briefly touched on above, so a full consideration of his methods of work, the form the reports should take, and their distribution to the papers, will be dealt with in the next article.

HON. SEC.

THE WEEK IN HISTORY.

Sutton's Panoramic Lens.

Of wide-angle lenses there is one which is rarely heard of nowadays, and I do not suppose one photographer in ten would credit an account of its performance over the wide angle of 125 deg. But nevertheless the "Panoramic" lens, of which Thomas Sutton published the first account forty-four years ago to-morrow in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, might be found serviceable in these days of rapid roll-film. For the "panoramic" lens possessed at the time of its invention two fatal defects: it required a very small aperture to remove its spherical aberration, and it possessed curvature of field to an extent which rendered necessary the use of curved plates. The lens itself was concentric in design. It consisted of two thick concentric shells of flint glass enclosing a space filled with water. It could be made achromatic by suitable choice of curvature, and the question of unequal illumination was got over by Sutton by employing two diaphragms, placed equidistant from the centre of the sphere of which the whole lens consists, and from the concave surfaces of the glass lenses. These diaphragms were made elliptical, the long axis of the aperture being in the horizontal direction.

Though very little used in the days of glass plates, such a lens

as this now obsolete "Panoramic" might be of commercial value for roll-film photography.

The Latent Image Sixty-five Years Ago.

In an earlier instalment of these notes I recorded Fox Talbot's discovery of the latent image ("The Week in History," February 19), and the reader who is interested in the account of this fundamental factor in photographic technique can turn back to the quotation there from Talbot's original words. But it may not be out of place to say that on Wednesday next, September 20, exactly sixty-five years will have elapsed since Talbot discovered this important fact. Writing an appendix to Tissandier's "History and Handbook of Photography," Fox Talbot himself named September 20 and 21, 1840, as the dates on which these observations were made. The discovery, he goes on, "immediately changed my whole system of work in photography. The acceleration obtained was so great, amounting to fully one hundred times, that, whereas formerly it took me an hour to take a pretty large camera view of a building, the same now only took about half a minute; so that instead of having to watch the camera for a long period and guard against gusts of wind and other accidents, I had now to watch it for barely a minute or so."

HISTORICUS.

Woking and Ripley, with their surroundings, is the district dealt with in the latest number of the Handbooks issued by the Homelands Association, Ltd., of 22, Bride Lane, Fleet Street, E.C. The volume is the forty-second of the series, and is written by Mr. Arthur Henry Anderson, whose lecture before the Society of Arts and articles on the "Decline of the Country Town" have attracted considerable attention within the last few months. The book is illustrated with twenty-six copyright photographs, mostly from the camera of Mr. J. A. C. Branfill. It includes chapters on the bird life and botany of the surrounding country from the pens of Mr. D. W. Collings and Mr. Harold W. Monington, F.L.S., respec-

tively. It forms part of the Survey of Surrey undertaken by the Homelands Association, and is published at 1s. paper cover, 2s. cloth bound.

AN IMPROVEMENT IN CORKS.—A. Gawalowski, in a German contemporary, proposes firstly to remove the encrusting matters from the cork tissue, leaving a kind of cellulose, and, secondly, to treat this with 50 per cent. sulphuric acid, whereby it is converted into a material akin to that of parchment paper. The corks are then impregnated either with paraffin or rubber solution, by the aid of reduced pressure, and then form a very good substitute for rubber stoppers.

THE CONVENTION OF THE PHOTOGRAPHERS' ASSOCIATION OF AMERICA.

THE twenty-first annual Convention of the Photographers' Association of America met at Boston, on August 8, under the presidency of George Graham Holloway, of Terre Haute, Indiana. The Association, we may say, represents American professional photography, and the Convention, during its stay in Boston, devoted itself to the discussion of topics important to the professional photographer. This part of its programme occupied the greater part of the time, and although entertainment was provided for members through the good offices of the "Photo-Era," the Convention was primarily a conference of men of all ranks in the profession, met together for the purpose of knowing and instructing each other. In America a convention on these lines appears to be infinitely more successful

than in this country. The American professional does not take the view that his competitor is necessarily his enemy, and as a result the convention meets in a spirit of fraternity which helps forward photographers as a body. A list of those taking part in the meetings would interest only a few of our readers, but we may say that it includes foremost professionals from all parts of the States, in addition to representatives of the leading manufacturers. An exhibition of professional portraiture was held, and medals and certificates awarded. We cannot quote from the report of the various proceedings, but we may reprint here, by courtesy of "Wilson's Photographic Magazine," which devotes its September issue solely to the Convention, several of the papers and discussions.

THE MANAGEMENT OF THE RECEPTION-ROOM.

(Papers and discussion before the Convention of the Photographers' Association of America.)

This session of the Association was introduced by the following short paper by C. Wesley Hearn, under whose superintendence the subsequent discussion was conducted:—

The difficulty has been heretofore that the work we did under the light has not been properly taken care of in the reception-room. The ideal reception-room lady is not one who will sell anything that there is money in. In other words, the party who simply waits upon the office in a mechanical way, without any thought or idea in relation to what would be best for the pictures we make, is not backing up properly the work which we do under the light. It very often happens that we make a thing with a certain definite idea, and if the party in charge of the office is in sympathy with our ideas, and has become a second to us in carrying out those ideas, then we shall stand a chance of giving satisfaction, and at the same time doing our work with credit to ourselves.

We may make a three-quarter figure of a lady. The attendant in the office may possibly decide that if the customer likes an oval picture she will put it on the oval picture, without any regard whatever as to whether that is best. With a desire to sell high-priced goods she may also advise delivering that picture on mounts and things of that description, purely with the object of getting that money, when it may be advisable for the best interests of the photographer that those pictures should be treated in some different way.

The Receptionist's Duties.

I do not think that the ultimate aim of a reception-room lady should be that she should make the money-getting part of the business the only thing. I would like to recite a little of my own personal experience in the last few years—of how I have changed my method, having first had my attention called to it.

We have in Boston, as you know, an organisation called the Lens and Brush Club. About every photographer that is progressive, in the vicinity of Boston, is or has been a member of that club. We have lectures by artists upon how things should be

done, and we have in consequence thereof received an education in that respect. I have made a point to have my principal attendant go to the meetings of this club on ladies' nights, and I have seen a radical change in the result of my work.

Interest the Customer.

Now we are busy under the light; we make a variety of pictures with the idea of giving honest goods for the money, and if we do that we have made friends and we have done the best thing that we could for ourselves. A lady, appreciating that, has made it a point to try to learn these various methods and means. Now when a customer comes in—outside of the usual pleasant reception which is supposed to be always given—she tries to get the customer to ask her advice in regard to which is the better way to finish the work.

We know very well that if left to themselves the customer will pick out something or other which pleases their fancy, and the ordinary reception-room lady will give it to them. The reception-room attendant should receive your strict attention all the time, to educate her for what is best. Your customers will then refer to her and she will advise them, and your product will be more pleasing to you than in the other way.

I think the time has gone by when we should only get all the money that there is in it. I have one strict rule—always to leave enough car-money for the customer to get home with. (Laughter.) I insist upon that absolutely. But there are cases which arise when you have customers that have plenty of money, and the product that they buy is largely what you recommend.

Now if you do not attend to your reception-room yourself, try to give a little attention to this plan of educating the attendant.

C. WESLEY HEARN.

Mr. George G. Rockwood, of New York, communicated with the following paper:—

The reception-room is, after all, allowing that the standard of work is correct, the keynote of any photographic business. Here all the honour (and profit) lies. It is the impression, both mental and physical, the patron receives when he enters there that unconsciously guides him or her in all negotiations or dealings with the establishment.

Taking the points as they successively appear to the patron, I claim the first is good housekeeping. The reception-room should be clean, neat, and above all not "cluttered up." From the

entrance to the exit this should be looked after, and there should be an atmosphere of cheerful refinement, and not that of a truck-shop.

How to Furnish the Reception-room.

The reception-room should have only interesting pictures, not necessarily portraits or even your own. There is nothing more uninteresting than portraits of the normal individual. If portraits, let them be of people of prominence or of high artistic quality as pictures. Above all, do not leave a pile of "left overs" or

refused" on the counter for people to muss over. Your customers may think they will have no better success. In my studios I have examples are in portfolios or boxes which are shown one at a time, as in all "shopping"; the customers are confused and often lost by the multiplicity of "samples" before them, and they sometimes retire to gather themselves together, or go to some other establishment where more tact is employed. In my new studio, which to me is ideal, there is not an ordinary or uninteresting picture to be seen, and, so far as the eye sees on entering, there are not half a dozen in sight. Some are purchased photographs of famous pictures by Reynolds, Rembrandt, and others, and the glare of the windows is subdued by panels of stained glass in the centre of which are half-life transparencies of President Roosevelt, ex-President Cleveland, Mark Twain, and other men of the day, with heads of beautiful children.

This may not be practicable or even desirable with some, but the expense is not great, and the effect beautiful. I paid about \$5 each for panels 18 by 36, I furnishing 11 by 14 transparencies for the centre. You see I am placing much importance on the atmosphere or effect upon the reception-room, as there is created the first impression. Everything about the place should reflect order, thrift, cleanliness, good cheer, and system.

The Ideal Receptionist.

The next matter of importance, without which all fails, is a bright, careful woman at the desk, unless the owner assumes this rôle himself, and, in my view, no man can take the place of a woman, if she is fitted. There is no position for a business woman, who is not making it a stepping-stone to matrimony, offering such opportunity for usefulness as in a reception-room. With good education, good disposition, and tact, she can almost double an ordinary business as soon as she discovers the difference between opportunity and importunity. She should be intelligent, quiet, alert, courteous, and almost permit the patron to buy rather than force anything upon them. Such a position is pleasant and profitable, deserving, and in some instances receiving, as large a salary as the gentleman who officiates in the studio.

One season I estimated the increase of sales from what the patron intended to secure over the amount they *did* pay, and I believed

it to be over \$5,000. To induce this result, I not only pay a fair salary, but give a commission on the gross sales. However conscientious and desirous of doing one's duty your representative may be, the commission, be it ever so small, excites to still further effort. I am interested in five establishments, and, after many years' trial, I am convinced that this system is a good one. Of late years I have extended it to the man behind the camera, with like favourable results.

Re-sittings.

In the discussion of the reception-room, properly comes the consideration of re-sittings. My instructions are never to hesitate to grant re-sittings unless it is for some fault that you can make plain to your patron is mechanical and can easily be removed in finishing. The re-sitting is usually inevitable, hence do it cheerfully, and thus save yourself from loss of both money and customer. The public have some rights which even a photographer should respect, and without question. Almost everyone has seen in pictures made of themselves an expression or sentiment which they did not feel, and which seemed to be a libel on them; while from a technical standpoint they were excellent. Again, a prompt compliance with the desires of the patron sometimes causes them to reverse their judgment and accept the proofs. This has happened in innumerable cases with me. Of course, there are people who demand great patience under most exasperating circumstances. I am not sure that if Job had been a photographer he would have gained his inheritance.

Now, having secured your patron, talk about the other fellow. Your personality may be interesting to you but not to your patron. Do not endeavour to impress him or her with your assumption that Rembrandt, Raphael, and yourself were young things together, but direct your attention—sometimes it must be your ingenuity—to finding some grace, some comeliness, or beauty in them. No human being is so unfortunate as to be without some favourable quality. One can find something—dress, shape of head, hand, or figure—to notice in delicately expressed words or suggested compliment. Having taken our subject to the door of the studio, not operating-room, we leave him to be discussed by those to whom the subject has been allotted.

GEORGE G. ROCKWOOD.

The work of the reception-room in its commercial aspect was discussed in the following paper by C. L. Lewis:—

Reception-room Methods.

Two years ago I came to the conclusion that I would stop selling photographs like buns and eggs, so much per dozen, and adopt the plan (not, of course, original with me) of charging so much for the sitting and so much each of the prints. At the outset this necessitated considerable explanation on the part of the receptionist, with whom the plan met with some opposition. However, she soon became more adept in explaining the plan, and it became easier to make the people understand, and as I sat near by in the office and could overhear the conversation, I would hear from the customer almost without exception, after it had been made plain: "Oh! I like that; then I can have as many as I want."

A Question of Price.

Now here is the point. I was getting but \$12.00 per dozen for pictures, and I wanted to raise the price to \$15.00. My people, I was sure, would not stand the price. A lady drops in to see the styles: "How much are these?" "Fifteen dollars per dozen, madam." Scene: a catching of the breath and raising of the eyebrows: "Indeed? Well, I was just looking; I will come again." Gone!

The new way:—Lady asks how much per dozen. We do not sell pictures by the dozen. For this (cab.) size we charge \$3.00 for the sitting. Mr. Lewis makes as many negatives as he finds necessary

to secure satisfactory results, and then you order from the selected proofs such as you want. The prints are only \$1.00 each. Then comes the expression: "So I can have just as many as I want. Oh, I like that plan!" Now, just as if they could not always have had just as many as they wanted! It is just the difference between tweedledum and tweedledee, but tweedledee seems to suit them better, and you have avoided delivering the knock-out blow—the mention of \$15.00; and instead have registered an appointment for a sitting.

Receptionist and Operator.

So much for the regular method. But as to further methods of handling peculiar people, and the harmonious working together of the artist in the studio-room and the artist in the reception-room, for both should be artists in their way. A perfect understanding must exist between the two. My experience has taught me that the feeling of anxiety and nervousness so often noticed in the studio-room, at the outset, is quite as much in evidence in the reception-room, and requires the same skill on the part of the receptionist as is demanded of the operator to overcome it. In fact, half the work can be done in the reception-room, anyway. The duty of the receptionist, after satisfying the customer with the work shown, is to convince them that the operator has a perfect understanding of what they want; moreover, by putting the matter entirely in his hands

he will doubtless think out something for them far more suitable for their individual case than anything she has shown them. Of course, at the outset they have decided on some style shown them, but it is her business to see to it that before they reach the studio-room that they are content to let Mr. Operator make anything he pleases, as they have conceived the idea that he is the man of all men that will know what they want. An operator thus fortified by a clever receptionist must make the stuff or show reasons why—and there are no reasons.

Handling the Sitter.

The peculiar people I refer to are those who "want to see the man who is to make the picture." Some there are, as you all know, who will not decide upon anything until they have seen this man. Now this man is, or should be, a busy man, and to hustle out just after having a difficult sitting, to meet some peculiar woman who has already worn out the receptionist, and do so, bubbling over with good nature and artistic zeal, requires more of the grace of God than the average "wizard of the camera" possesses. However, here is an excellent chance to make an impression, for impression is what is expected. A glance at the expressive face of your receptionist—and, I insist upon it, she must have an expressive face—tells you the whole story. You sit down—I prefer to have my customers seated, and to sit with them. Let them take the initia-

tive in the conversation. You use your eyes and ears. Soon you have encompassed the situation. In response to their remark: "What are you going to wear?" and you have done the trick in the next five minutes, anyway, and you will have plenty of time to think of what you will say next, for of all subjects a woman is best to talk about her clothes. If, by the time she has described the four or five dresses—any or all of which she might wear—you find you want more time, ask her if she has a hat she could wear with that blue evening gown, and you will secure a few minutes longer. By this time there is little need of saying more. She is convinced you are interested in her. A few judicious remarks about how well you think she would look in this or that, and you ask the girl for the appointment book, and down goes the appointment, and you bow the lady out. After getting outside, her companion asks her what style she decided upon. She says: "Why, I don't know; but Mr. Blank has some ideas which I know will be a right." Style, price, and all difficulties have vanished by the use of a little—what shall we call it?—tact. But someone says "That won't apply at all studios." Well, probably not to those diseased studios, infested with the "ticket" germ, the only cure for which is a change of climate. Opinions will vary, but while a man may handle his opinions his convictions will handle him.

C. L. LEWIS.

From the subsequent discussion of the foregoing papers the following quotations may be made:—

Mr. Puffer: I have studied this one thing: that to please my patrons is the most vital point in the success of my business: especially as I had all to gain and nothing to lose in going to New York, where it is a very large field which requires the utmost that there is in a man.

I decided to try to produce work that would please the people, and I make that my aim. I very often have to sacrifice some cranky notions that I have for the sake of the people who are paying their good, hard-earned money for my work. I have carried that idea out to such a degree that I could name on the fingers of my one hand those resittings that I have had to make in two years. This is simply because I do the work myself—I trust it to no one. I have had two employees; one stayed with me six or seven years and another eight years. I could safely say that one of them was one of the best retouchers in this country; but I found that in trusting the work to someone else it is very often unsatisfactory, and a prejudice is formed against the work, so that I had to give resittings. For when the prejudice is once formed it is impossible to overcome it except with a resitting.

Now the secret, I think, of the whole thing is that I get enough for my work, so that if I want to make fifty plates I can stand it. That aim to create artistic work has developed in me more within the last two years, because I have confined myself to the very best that I could do, and would not turn out a thing that was not the best that I could do. My customers cannot buy anything that I think is bad work, even though they think it is good.

Mr. Hearn, in closing the discussion, said:—

Pirie Macdonald had a custom some years ago, when he made his famous reputation, of submitting his pictures to the boy round the place. If he could only get the boy to give his honest judgment he thought he had an opinion worth having. That scheme carried out by us in our work often suggests certain ideas to us.

The customers who come in with the proofs have no idea what they want. They want some pictures. Even when they come in to sit they have not generally an idea of what they will have made.

They leave it to you. It is up to you to make good, honest work, to give value absolutely for what you receive. Do not advise expensive pictures if you have made a blunder in your negative and will look better upon a cheaper paper. Give them what the picture is worth in that case. Then from other negatives, in which you have not made a blunder, sell them other things.

I wish to speak of a photographer who was a wonderful success as a salesman. He had the nicest way of talking to his customers. The way he handled his goods over the counter! Everything was just perfect, and excited the admiration of the best of us. But there was one unfortunate thing about him. At heart he was no honest—he was a deception. His methods, if backed up with an honest intent on his part, would be good. If he were delivering a parcel of photographs he had a very nice way of opening the envelope and taking one of the enclosed photographs out of it. He would take that out and hold it so choicely, and present it to you for your consideration in such a way that immediately you were inspired with the idea that there was something very choice there, before you had even seen the picture. As I watched him I saw a smile on the face of the customer—they knew they were going to like the picture because it was presented to them so nicely. The photographer would say: "I think that is a very good photograph; am I not correct?" He was a slick article, but he did it well.

This puts me in mind of another thing. The very way that you greet your customers, the reception that you give them, the impression that you convey to their minds from the moment that they come into your studio until they are through with you for good for the time being, lives with them and is associated with your work. Whenever they show their friends those pictures, immediately comes to their mind the unfailing courtesy and obliging disposition which you showed to them.

Here is another idea. If you are by nature crabbed and rough, do not wait on your office; hire somebody else to do it for you. A great many people are unable to do anything of that kind gracefully. Make it a point to have your customers associate their pictures with the best of treatment from your hands.

The publication of the text of another paper on "The Financial Side of our Profession" must be held over until our next issue.

FOREIGN NOTES AND NEWS.

Daylight Development.

AN example of the periodical notoriety which the method of developing plates without a dark-room contrives to obtain occurs in the current issue of "Le Moniteur," where there is a communication from M. H. Schwartz, of Cairo. M. Schwartz, however, deserves credit over other partisans of the daylight-development process, in that he does not ignore the weak place in the method—viz., that, if you have to use a dark-room to transfer your plate to some patent development chamber you might just as well finish the process in your dark-room while you are there. Admitted, says M. Schwartz, but I dispense with the dark-room, and find that I can change my plate into the stained developer in diffused or weak light. Here is the description of the method which it is stated has been employed with satisfaction for some years past:—I place myself in the corner of a room which is not directly lighted, but is feebly illuminated by the light of a paraffin lamp in an adjoining apartment. Close at hand I have two dishes, one of coloured developer and the other of fixing bath. The developer is dyed with any of the suitable colouring matters which have recently been advocated, such as fuchsine, crocine, scarlet 3B, or, more simply, with a solution of phenol phtalein, which assumes a deep-red colour in an alkaline developer. In a light which is sufficient to show what is going on, the plate is slipped from the dark slide into the developer, which is at once covered with a piece of opaque card, and development allowed to proceed until it is safe to bring the dish near a lamp and watch the actual appearance of the image.

M. Schwartz makes no reference to the difficulty which most photographers would find in judging the density of a negative as it lies in the dish, a difficulty which, save by the adoption of time development, or the provision of cumbrous mechanical appliances, is not readily overcome.

A Simple Method of Stereoscopic Projection.

In the course of a lecture delivered recently before the Vienna Photographic Society, and reported in the current issue of the "Korrespondenz," Prof. Dr. G. Jaeger describes several devices for stereoscopic work which, while none is in any sense sensational nor all entirely novel, should occupy those who make the stereoscopic form of photograph their chief interest. Prof. Jaeger has devised a simple form of stereoscopic projector, with the defect, however, that it permits the projection to be observed only by one person at a time. The positive is placed in a lantern provided with two projection lenses, and in front of these latter is rotated a disc,

Fig. 1.

which alternately allows first one and then the other picture to reach the screen. The disc is perforated as shown in the figure—i.e., it contains two series of holes, the distance between circles 2 and 3 being less than that between the eyes of the observer, and that between 3 and 4 being slightly greater than that between the projection lenses. The disc on rotation uncovers first one picture

and then the other, and the observer, looking through the half of the disc which lies to the right or left of the projection lenses, sees each picture with the eye corresponding to it. It is found that the two pictures need not necessarily register on the screen in order that the stereoscopic effect should be perfectly observable.

The Polaristereoscope.

Prof. Jaeger has also constructed a stereoscope, in which is applied the property of one Nicol prism to transmit or intercept light falling upon it according as the light has come from a Nicol prism placed parallel or perpendicular to it. The pair of positives is placed in a projection apparatus such as that required in the method already described, and observed by transmitted light, which light, after its passage through the projection lens, passes through a Nicol prism, and falls upon a screen of ground glass as linearly polarised light. The planes of polarisation of the two positives are arranged perpendicularly to each other, and the picture as a whole is seen on the screen like any other projection. But on providing each eye with a separate Nicol corresponding in plane of polarisation with the respective pictures, we assign to each eye the observation of the appropriate image, and the result is a true stereoscopic effect.

[The above system appears to be identical with that of Anderton.—Eds., B.J.P.]

A "Concentration" Stereoscope.

On projecting the two stereoscopic images with the projection apparatus image on to a large lens, *L*, images are obtained at the points *A* and *A'*, the distance of which, by suitable choice of lens, can be made to correspond with the space between the normal human eyes. The eyes being placed in these positions, that at *A*

Fig. 2.

receives light only from the point *O*, that at *A'* only from *O'*. As the two combine to a single impression, the observer obtains the effect of solidity, and, as the whole of the light reaches the eye, the source of light in the projection apparatus can be very weak.

Next Year's Congress des Societes Savantes.

The forty-fourth meeting of this congress is announced for April 17, 1906, when the members will assemble at the Sorbonne for the reading and discussion of papers. Manuscripts are to be sent to the Minister of Public Instruction before January 30, 1906. In the photographic part of the physical sciences section, the following syllabus has been drawn up as roughly suggestive of subjects on which communications may be made:—Photography of radiations and other phenomena—The action of various rays of the spectrum on sensitive photographic plates—Orthochromatic plates—Plates approximating to ocular sensitiveness—Photographic optics and the optics of shutters—On the preparation of a sensitive plate with the fineness of grain of older processes, such as albumen and collodion, but with the properties of modern gelatino-bromide—The physics and chemistry of development, toning, and fixing—Influence of temperature on the sensitiveness of plates—The development of the latent image—Photography and radiography applied to science—Stereo- and micro-photography.

Liquid Dark-room Safe-lights for Orthochromatic Work.

A new type of dark-room lamp has been devised by Dr. E. Stenger and placed on the market in Germany. The ordinary incandescent

electric lamp is surrounded by a cell containing a dye solution, with which the receptacle can be charged, and of which it can be discharged as may be necessary. Moreover, the lamp can be at once removed for renewal or repairs. Dr. Stenger, who describes the lamps in the current issue of the "Zeitschrift für Wissenschaftliche Photographie," has made measurements on the extent of evaporation of the solution during a short time, and has found it negligible in one hour after lighting. The lamp attains its full temperature six hours after lighting, and in the course of twelve hours' use was found to have lost only 24 grammes of water by evaporation. The liquid filters, of which the formulæ are given in the next column, are those used by Dr. Stenger, and are found greatly superior to ruby glasses in point of brightness for the same, or a much higher, degree of safety.

Tartrazin .05 per cent. solution absorbs to λ 510.
 Potass. bichromate 10 per cent. solution absorbs to λ 550.
 Potass. bichromate 10 per cent. solution, with fuchsine 1 gm. per litre, absorbs to λ 620.
 Potass. bichromate 10 per cent. solution, with fuchsine 2 gm. per litre, absorbs to λ 630.
 Potass. bichromate 10 per cent. solution, with fuchsine 5 gm. per litre, absorbs to λ 635.
 Potass. bichromate 10 per cent. solution, with acid violet 2 gm. per litre, absorbs to λ 650.
 Tartrazin .05 per cent. solution, with acid violet .2 gm. per litre, absorbs to λ 645.
 Tartrazin .05 per cent. solution, with methyl violet .2 gm. per litre, absorbs to λ 660.

AN APPRECIATION OF STRAUSS.

[Mr. J. C. Strauss, of St. Louis, has always compelled our admiration, not purely for his versatility in photography, but for the genius with which he makes himself one of the men—and his studio one of the places—of St. Louis. This side of Mr. Strauss' talent is exhibited with some prominence in an article in the "Mirror" of St. Louis. We reprint with the article a reduced reproduction of the caricature portrait of its subject.—EDS. B.J.P.]

No, that is not a nursing bottle which he holds in his hand. It is the bulb by pressing which he closes the camera-shutter and signals that you are no longer to sprain your face in an attempt to "look pleasant." If your endeavour to look pleasant results in such a smile as Caricaturist Bloch puts on the face of his subject, you are sure that the photograph will hardly fail to do you justice for your many sins. Mr. J. C. Strauss, the greatest photographer in the world, did not pose for this picture. His business being to pose others, he cannot pose himself; the shoemaker's children are rarely well shod. Strauss is an artist with a cynic streak through his kindness. Why not? What is photography of men and women but a study of their vanity, and what is more wearying than the vanity of other people, even when it does make you a fortune, build you a bijou studio, and enable you to charge as high as 100 dols. per dozen for the photographs.

Strauss is a condemned optimist. He has to put a good face on everybody and everything. He is forced to take well with people even if he has to take all their spare cash every time he takes their pictures. Strauss has to jolly people into looking their best, and then he has to improve on that best with a few touches upon the negative. Withal is Strauss no fakir, for he does, more than any man of his craft, get character into his photographs. The others generally take out character to obtain prettiness. Strauss has humour, and, therefore, he puts some of it in his work, with the result that his subjects are never pictured quite too consciously as being "stuck on themselves." That quizzical look he wears stamps him as the "jollier" par excellence, and your artistic "jollier" is the man who can put his victims on their best appearance. He takes a picture of you that delights all your friends, and all the time he is taking it you feel as if he is guying you for being so concerned with yourself as to think people want your picture.

A Strauss photograph is never conventional. It has an "atmosphere," which most photography has not. He is daring in his unconventionality, and particularly in his unhesitating application of the method of the painter and draughtsman to heighten or soften, strengthen or diffuse the picture-making of his servant sun. This painting quality in his photographs is their unique distinction throughout the world. His effort is for truth of the inner ego of

the sitter rather than for a merely pleasing arrested shadow of that sitter's facial superficialities. Commercial he is in a way that does justice to the Jewish blood of which he is so proud, but while he gets his price he gives value. He will use up more plates on one sitter than any dozen other photographers. He will work over a sitting all day until he gets it right. He will have it his way, the right way to his thinking, before done with it, and then it is done. He is as whimsical as Whistler, and at the same time as careful as a miniaturist, with a shrewdness in handling people that has made them "come again." Strauss does not cultivate patrons. He pays more

attention to a whole lot of people who cannot afford his prices, like the artistic contingent during the World's Fair, writers, men of note, but not of money, and they being of the world of "the know" have assured the others, the profitable others, that the right thing in photography is the Strauss brand. His pictures of women are remarkable for truthfulness, and yet the women shun him not. That is a triumph. Strauss is the poorest speech-maker and the worst poker-player in the whole wide world, but he makes an inimitable cocktail, and he has a man or woman "mugged" and done with before they know it. He gets the money, and he gets it from the wisest people. He is not less a hypnotist than Elbert Hubbard in that regard. Strauss is far from being the least of the men who have made St. Louis famous by good work. He is one of the few men you are asked about when you are away from home. And he is one of the fewer still concerning whose distinction in his

There need be no wonder, for he is of unique character as a man, in addition to being an originating individuality in an art that is only saved by such as he from becoming mere mechanism and button-pushing and trickery. He leads in his class, and his class is the topmost best. He makes it pay—yes, and he rather laughs

at how easy it is done, and then he likes to put much of his profit into edibles and potables and get a gang of Bohemians into the "Growlery" underneath his studio, and—"forget it" in a way to make them all go out at ever-so-much-o'clock in the morning, a band of boomers of the art and heart of Strauss the smart.

THE PHOTOGRAPHIC SALON.

A FIRST IMPRESSION.

The thirteenth annual exhibition of the Photographic Salon opens its doors at 5A, Pall Mall East to the public to-day. At the private view yesterday we gained a general impression that this year's show will be regarded as one of the best that has yet been produced under the ægis of the "Linked Ring." The Salon has commenced to be reasonable. The character of the work this year tends less to the striving after bizarre effects, which appear to have been the sole aim of the bulk of the exhibitors at certain previous Salons, and a display of pictorial work savouring less of affectation is the result. The environment of the present show has been suggested as a contributory cause of this return to saner photography. The room in which the exhibition is held is the old home of the R.P.S. exhibitions before the finer and more suitable quarters afforded by the new Gallery were obtained in 1899, and the effect produced is more cheerful and brighter than that which seemed to prevail in the somewhat gloomy atmosphere of the Dudley Gallery.

This may be due to the fact that the added space afforded by the greater wall accommodation has been made the most of in the capable hands of Frederick H. Evans, who is again solely responsible for the hanging arrangements, or it may be the suit of green arras cloth with which the Salon's new quarters are draped has something to do with it, but anyhow we are thankful for the relief. The green colour of the background is very restful to the eye, and, as thirty less frames are hung this year than last, the background has plenty of opportunities of being seen. A moulded cornice of cream and gold, and a dado of a brown colour, heighten the good impression created by the disposition of the frames, which are again arranged in groups, the panelling being formed by thin gold beading instead of the somewhat obtrusive white beads previously employed. The lighting of the gallery is good, but when the sun is shining the reflections from the glass of many of the pictures will be found rather troublesome. In fact, most of the work hung in the far corner of the room, which will doubtless be known as the "hot French corner," because of the brilliant reds of some of the pictures of the French photographers hung there, will have a very trying time if there is much sunshine during the run of the exhibition, as the sun strikes right on to this section of the walls during the greater part of the morning.

Although the general effect is more cheery, and the bulk of the pictures are good, we do not mean to infer, however, that weird efforts and glaring examples of "faking" are entirely absent from this year's exhibition. It would not be our own Photographic Salon if this were so. We have come to look for these specimens of the extent to which a beautiful and wonderful process may be tortured, and would confess to a feeling of disappointment if they were absent. It is to the credit, however, of English photography that most of these examples of mental strain and misplaced energy are to be found among the works of the American and Continental schools. As the foreign works were chosen by the Selection Committees of their respective countries, no blame can be attached to the

English "Links" for the inclusion of some of these fearful and wonderful productions of handwork.

To that important personage, "the man in the street," this year's Salon will still present a certain amount of material for thought and amusement. The aspect of such an individual is somewhat fittingly illustrated by the first and last pictures in the exhibition. No. 1, by Will Cadby, is a simple little child study. Here we have depicted "Innocence." This is the state of the mind of the man from the street as regards pictorial photography when he enters the portals of 5A Pall Mall East. No. 254, the last picture, is by J. Page Croft. It is entitled "Disdain," and it portrays a female head, "with wrinkled brows and sneering lips." This may be the state of the man returning to the street. Anyhow, to the great body of pictorial photographers who know their Salon the show will appeal as not only interesting, but as containing some really good things. Hinton's are well to the fore, and can be easily spotted. The Jobs are poor compared with previous work from this master of landscape work. The Keighleys are obvious, but have a very marked tendency to flatness this year that detracts from some very fine compositions. The Craig-Annans are of the best, and that is very good. No. 24, "Miss Jessie M. King," is the finest thing of its kind in the show.

The David Blounts are somewhat weak and scratchy, but clever withal. The Cadbys are dainty as ever, but the weird monstrosity by Mrs. Cadby, entitled "The Cat that Walked, by Himself," is more fitted for the technical section of the Royal. It may make a good picture postcard, however. Of the work of Charles Moss only one sample is shown, but that demonstrates amply what can be done with a negative, some gum and pigment, and plenty of time and patience. Reginald Craigie has also only one portrait this year. The Beningtons are disappointing, and the Ward Muirs are trivial. The Evanses are versatile, and the portrait of H. Horsley Hinton underneath "The Hill Top" does not do Mr. Evans credit. The Callands are good, as usual; the contributions of Mrs. Barton and F. J. Mortimer betray themselves at once, and the variety of Arthur Marshall's work does not detract from its excellence. The American pictures are hung together, as also are the works of the Continental exponents of the use of the camera, and among the latter the productions of Dr. F. V. Spitzer, R. Duhrkoop, Heinrich Kühn, R. le Bègue, C. Puyo, G. Grimpel, Demachy, and Steichen stand out for recognition. Of the Americans Mrs. Kasebier, Alvin L. Coborn, Alfred Stieglitz, J. T. Keiley, and Clarence White are well to the fore, and their work and that of the English exhibitors will be reviewed in a future article. It will be evident from even this brief list of the exhibitors that this year's Salon is a strong one, and the general impression created is that it is a "portrait" show. One of the pictures that will probably compel much attention is a very fine figure composition by F. Benedict Herzog entitled "A Tale of Isolde." It is also a most flagrant example of handwork, and its price is only £100.

A SCHEME THAT PAYS.

AN example of trifling with the dignity of the President of the United States (says the "Pittsburg Post") may be seen at a tin-type studio on Smithfield Street, this city.

Passing along the street, one is almost startled by this invitation, placarded in front of the studio: "Come in and Have Your Picture Taken With the President." Near the placard is a cabinet in which are displayed pictures showing President Roosevelt standing in a group of young men, or in the attitude of shaking hands with someone. One of the pictures has the Chief Executive standing behind a young woman, who is sitting in a chair.

It would seem that the privilege of having one's picture taken with the President is put forward as a drawing card. The artist says it is making a great hit with his patrons. The idea of being able to show a picture of one's self standing beside the President of the United States has fascination for many, says the artist. Girls particularly like the idea, he added.

The scheme is worked out by having a large picture of the President on a background canvas. Those desiring to have their pictures taken with the Chief Executive arrange themselves about the painting in the background.

To produce the handshaking effect, a slit is cut in the canvas on which the President's picture is painted. As this picture shows the President with one of his hands in his pockets, the slit in the canvas is made at the pocket. The person who wants to be shown shaking hands with the President puts his hand partly through the slit, producing the desired effect.

In rivalry with the President-picture scheme as a drawing-card is a back-ground canvas containing the pictures of two picnic-girls. One of the girls holds a guitar and the other a mandoline. If a young man would give the impression that he is popular with the girls, he may sit before the pictures on the canvas. The effect suggests the idea that the girls are singing to him, and his face may wear a look as of one being bored or delighted, according to taste.

BIRTHDAY PHOTOGRAPHS.

IN an interesting interview with an American photographer in the "New York Sun," a method of making and collecting a series of autobiographical photographs is mentioned which, although apparently quite an old idea, opens up a new field for the pushing photographer in this country. The American worker says:—"I have taken that man's picture on the second day of August every year for twenty years," said the old photographer, as a sitter passed out of the studio. "August 2 is his birthday, and he has faced a camera on that day every year since he was born. He is now fifty-six, and in an album at his house he has fifty-six pictures of himself, and there is room in the book for seventy. If he lives beyond the allotted threescore and ten he will get another album. He first came to me the year after I began business. The photographer who had made his birthday pictures for many years before that had died, and the new proprietor did not please him. The first time he came in he said nothing to indicate that he was other than an ordinary passing customer. Then on August 20 he came back with a woman about his own age and had a picture made of her. On the 18th of the next January he came with a boy of sixteen and had his picture taken. By that time I had begun to feel pretty well acquainted with him, and he told me the story of the photographs. His father had lost a favourite son, before my friend was born, of whom a picture had never been made. The old man had mourned the dead boy, and his grief was the more keen because he had no effigy of him. So he declared that if he was ever blessed with another son he would have his picture the day he was

born, and on every birthday after. Accordingly, on the day a customer came into the world he had a picture made of him in his nurse's arms. On August 2 every year thereafter as long as the father lived he took the son to have his picture made. After the father's death the birthday photograph habit was kept up, and the pictures gave so much pleasure to their owner that when he married he established the custom in his household, and had a picture of his wife made on her first birthday after their marriage. Children came to them in due time, and each little one was photographed on its birthday and on every anniversary. He has an album for each member of his household, and I can assure you they form an extremely handsome and interesting series of human documents. Two of the sons are married and live far away from New York. They follow the custom their father taught them, and each year send him pictures of themselves and their families, and in return pictures of all those at home are sent to them. As a photographer I may be a bit partial to the custom, but I cannot imagine a more delightful plan for keeping alive family affection, nor a more interesting book than one of those albums, carrying its hero through the seven ages of man. These albums are not only valuable to those who are bound to the originals by ties of relationship and love, but the historian may see in them the progress of fashions in apparel, styles of hairdressing, and the advancement made in the art of making pictures."

New Materials.

Matt Rough White "Seltona." Made by the Leto Photo Material Company, Ltd., London E.C.

A trial of the new grade of "Seltona" strengthens the good opinion we had formed of the other varieties of this self-toning paper. The surface of the paper has a distinctly pleasing grain, and is yet sufficiently fine to preserve all detail. Self-toning papers appear to fill a want among the present-day photographers who desire not only reliability and uniformity in results, but who also want to obtain those results with the least possible expenditure of trouble. "Seltona" can therefore be recommended as fulfilling all these qualifications, and moreover is obtainable with a variety of surface to suit all tastes and purposes. The procedure for the production of warm brown tones on this paper is simplicity itself. The prints are made in the same way as ordinary P.O.P., but the printing is carried considerably further. A fixing bath composed of 2 oz. of hypo dissolved in a pint of water to which a pinch of bicarbonate of soda has been added, is all that is required. The prints are first slightly washed for a minute or two in a couple of changes of water, and placed in the fixing bath for twelve to fifteen minutes. They are then washed and dried. That is all. And prints result rivaling any produced by separate toning and fixing on ordinary P.O.P. If colder tones are desired, the prints are placed in a bath composed of 1 oz. of common salt dissolved in half a pint of water before fixing. The new grade Seltona should certainly be tried by all wanting a reliable moderately rough surface paper for printing-out purposes. The paper is sold in packets at 6d., 1s., and 1s. 6d., and in sheets.

The Watkins Dark-room Clock and Factorial Calculator. Made by the Watkins Meter Company, Hereford.

There is no doubt that factorial development is slowly but surely receiving recognition among every class of photographer. To Mr. Watkins is due many of the little helps to make smooth the path of the worker who desires exact results with as little trouble as possible, and in the new dark-room clock and factorial calculator

further incentive to rely on what may be termed mechanical methods is introduced. It appears to be quite settled now that the principles of the Watkins method of development are perfectly sound. Investigations show that the time of appearance—that is, the time elapsing between pouring on the developer and the first appearance of the high lights of the image in a negative—is a sure guide to the total length of development under ordinary variations of temperature and alkali. When the time of appearance is noted, it is multiplied by a factor to get total strength of development under ordinary variations of temperature and alkali. This factor varies with different developers. The "Watkins Factor" must not be confused with the "Development Factor" in the Hurter and Driffield system, but is merely a convenient term to express the amount of work to be done to secure the right contrast in the negative after a time of appearance has given the comparative speed at which the developer is working. A series of factors are supplied as a guide for most of the developers in use, but individual workers can work out factors to suit their own method of development. With the new Factorial Calculator the times of complete development, with various factors and times of appearance, are seen at a glance,

The Watkins Dark-room Clock.

The Factorial Calculator.

Moreover, being made of bright aluminium with the figures stamped in relief, can be seen easily in the dark-room. The outer scale is a scale of factors, and is also used to denote the total time of development in minutes. The inner movable scale denotes time of appearance, either in seconds or minutes. In use, the pointer is set to the Watkins factor for the developer, and against the time of appearance given on the inner scale will be found the total number of minutes to develop. This calculator can be used with an ordinary watch, but the new dark-room clock (a former pattern of which was called the eikronometer) will be found not only a useful adjunct to every dark-room for various purposes, such as timing exposures, etc., it is specially constructed to facilitate factorial development. It has many improvements over the old pattern. It has two hands, one of which completes the revolution in one minute, while the other takes ten minutes. The face of the clock is large, and the figures are plainly marked for use in the dark-room light. The ten minutes dial is right for the longest ordinary development. A stop motion permits both the hands to be started from zero as the developer is poured on. Legs are provided at the back to allow the clock to be used face up—the most convenient position in a dark-room. It is an English-made clock, and sells at 10s. 6d. The Factorial Calculator costs 2s.

"Nobra" Developer for Glossy Gaslight Papers. Sold by Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

"Gaslight" papers have now become such universal favourites among photographers of every class that any introduction to insure the best working and best results with this form of printing process deserves careful attention. The curious markings that make their appearance on papers of this description, especially the glossy varieties, have long been a source of speculation and annoyance to the printer who has a large output. The fact that they can be easily removed by

the aid of methylated spirit, rubbed over the surface of the dry print with a tuft of cotton wool, does not make the appearance of a developer that prevents the formation of these hair-like and spotty marks any the less welcome. The marks are usually stated to be due to abrasion of the somewhat tender film of glossy gaslight papers, either before or during development, and it is a fact that deliberate rough handling, such as drawing the paper carelessly from its packet, will cause them.

It is claimed for the new developing solution Messrs. Kodak have now put on the market that these markings are entirely avoided. Its name, "Nobra," is intended to indicate its non-abrasive qualities, and in our hands it fulfils these qualifications perfectly. The spirit that is necessary for the removal of the marks after development in the usual way, appears to be incorporated in the developer itself, and with the roughest handling, under-exposure, and forced development—certain methods of obtaining surface markings—prints of remarkable clearness were obtained. With correct exposure the developer gives on any gaslight paper clean, rich prints of good colour and entire absence of stains. Its use will save a great deal of trouble and extra labour where much work on glossy development papers is done, as we find it applies equally well to glossy bromide papers. The developer is sold in bottles containing 8 oz., sufficient to make 24 oz., at 2s. per bottle.

CATALOGUES AND TRADE NOTICES.

THE coming of age number of "The Picture Framer's Journal" has been sent to us. It contains a very complete list of every possible requirement of those engaged in the framing trade, in the shape of mouldings, tools, etc. There is in addition a very full list of pictures, engravings, and carbon prints included. The "Journal" is edited by Mr. C. G. Engert, and should be in the hands of every one interested in the work. It will be posted for 1s. by Messrs. Engert and Bye, North Finchley, London.

WE have received from Messrs. Marion and Co., Limited, of Soho Square, W., a specimen showcard for their "Iso" plates. The results given by an ordinary plate exposed under a graduated screen containing squares coloured blue, green, yellow, and red, when compared with those obtained on the "Marion-Iso" plate, make a very strong case for the latter. These showcards will be supplied free to dealers on application.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between August 28 and September 2:—

DEVELOPING APPARATUS.—No. 8,616A. Improvements in process of developing, fixing, washing, and drying webs of photographic paper, and in apparatus for carrying same into effect. Frederick Heinrich Lange, 79, Augsburgerstrasse, Berlin, Germany.

DISHES.—No. 17,425. Improvements in photographic dishes. William Laurence Parkinson, 15, Water Street, Liverpool.

CAMERAS.—No. 17,553. Improvements relating to photographic cameras. William Fraser Cloughton Kelly and John Arthur Bentham, 7, Southampton Buildings, Chancery Lane, London.

PRINTING.—No. 17,605. Improvements in apparatus for printing photographs. Frederick Heinrich Lange and Oscar Prange, 79, Augsburgerstrasse, Berlin, Germany.

DRYING ROLL FILMS.—No. 17,620. New and improved means for removing the moisture from photographic roll films after de-

velopment. Randolph George Goodwin, 38, Chancery Lane, London.

THREE-COLOUR PROCESS.—No. 17,608. Improvements in photographic three—or four—colour processes. Max Grünbaum, Norfolk House, Norfolk Street, London.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
16.....	South London Photo. Society ...	Outing to Uxbridge and West Drayton.
16.....	London and Prov. Photo. Assn.	Outing to Hainault Retreat, in combination with South Essex Camera Club.
18.....	Bowes Pk. and Dis. Ph. Soc. ...	"Time Development." Demonstrated. Mr. C. S. Carr. Competition of Whipp's Cross Outing Prints.
18.....	South London Photo. Society...	"Bromide Work." Mr. C. Winthrop Somerville, F.R.P.S.
19.....	Manchester Amat. Photo. Soc.	"Enlarged Negatives." Mr. C. J. Harrison.

A LECTURE ON CRYSTALS.

At a monthly meeting of the Rotherham Photographic Society, held on Tuesday evening, September 5, Mr. J. Leadbeater, a vice-president of the society, gave an interesting lecture on "Crystals and Crystallisation," showing by means of a vertical lantern how this beautiful process goes forward in regard to certain salts. He said: The subject of crystallisation had long been a most interesting one to scientists, and one that had puzzled them for years as to the forces nature employs to produce such wonderful and beautiful results. Opinions differ among scientific men as to the cause, and no true basis has yet been arrived at. It seemed to be generally understood, or, at least, it was the general opinion, that either electricity or magnetism, or perhaps a certain combination of both, acts on the molecules in the atmosphere, producing what is known as polar force; and it is by the action of this unseen agent that wonderful patterns are produced, the same force being at work which makes the beautiful designs of crystals on window panes.

Dealing with crystallisation from a photographic point of view, Mr. Leadbeater said the preparation of salts for crystallisation and photographic purposes was exceedingly simple. Let them make a saturated solution of any salt by dissolving in hot water, using as much of the salt as the water will take up. If a little sugar be added, or if the salts are dissolved in hot beer, it would tend to fasten the crystals more permanently on the glass when the solution has dried and the crystallisation has taken place; it will also act as a preventive against the crystals running off the glass while being subjected to the heat of the lantern. Having the solution in readiness, procure some pieces of clean glass, quarter or half plate, according to the size of condenser in the enlarging lantern, and coat them either with a camel hair brush, or by holding the glass level between the finger and thumb, and pouring the solution on the glass in the same way as would be done in coating a plate with collodion. After draining the glass a little while, lay it on a level stand for the crystallisation to take place. Crystallisation is accelerated by warming the plate before and after coating. Some salts will dissolve only in alcohol and crystallise much quicker than those dissolved in water or beer, because the spirit evaporates much more quickly. In order to photograph salt crystals an ordinary magic lantern is required, or, better still, an enlarging lantern, so that when the salts are crystallised on the pieces of glass, the plate may be put in the lantern and a negative taken from it, just in the same manner as an ordinary enlargement is taken; or if the

photographer is not possessed of a lantern, he may take a negative of the crystals by contact in the usual manner. Dr. Carpenter in his work on the microscope, recommends microscopists to work in this direction. If it is useful to microscopists it should also be useful to photographers, on account of the permanent records that may be made by photographs. Dr. Carpenter says:—"In this branch of science there are many chemical and mineral substances which give us a variety of both interesting and beautiful objects, some for their diversity and wonderful forms, and others for their elegance and beauty. The natural forms of such substances, which in any way symmetrical, are so in virtue of that peculiar arrangement of their particles which is termed crystallisation; and each substance which crystallises at all does so after a certain type or plan, the identity of the difference of these types furnishing character of primary value to the scientist."

Continuing, Mr. Leadbeater pointed out that it did not follow that the forms of crystals would be constantly the same from each kind of salts; on the contrary, the same plan of crystallisation may exhibit itself under a great variety of forms entirely depending on the strength of the solutions, that is to say, upon the amount of salts held in suspension by the liquid; and specimens of these such minute crystals are appropriate subjects for the scientist or photographer. The following is a list of salts which will give good class of crystals:—Chromate of potash, nitrate of barium, nitrate of soda, chlorate of potash, oxalate of potash, microcosmic salt, benzoic acid, phosphate of soda, acetate of copper, alum, sulphate of iron, acetate of zinc, citric acid, nitrate of uranium, and oxalate of soda.

SOUTHAMPTON CAMERA CLUB.—At the meeting held on Monday at the Philharmonic Hall, Mr. W. R. Kay read a paper on "Pin-hole Photography."

SHEFFIELD PHOTOGRAPHIC SOCIETY.—The Sheffield Photographic Society commenced the winter session on Tuesday evening, at the Builders' Exchange, Cross Burgess Street, with Mr. J. W. Charlesworth in the chair. An illustrated lecture on "Composition and Selection" was given by Mr. W. E. Tindall, R.B.A.

Commercial & Legal Intelligence

AURAL CLINIC, LIMITED.—Registered September 4, by Rodgers and Gilbert, 4, Walbrook, E.C. Capital £500, in £1 shares. Objects: To carry on the business indicated by the title and that of chemists, druggists, dentists, opticians, dealers in photographic materials, etc. Registered office, 102, New Oxford Street W.C.

PHOTOGRAPHER and Canvasser.—Edwin Morton, of 34, Cresswell Road, a photographer, was charged before the Croydon Borough Bench on a warrant with embezzling 3s., the money of Henry Lush, trading as H. Boyd and Co., of 223, Portland Road, South Norwood. Mr. Lush stated that the prisoner entered his employ in February as canvasser. He had to solicit orders and receive deposits. He had a nominal salary of 5s., 15 per cent. on orders for photographs, and 20 per cent. for enlargements. It was his duty to account nightly for all sums received, with the exception of 6d., which he was entitled to retain on each order, and the counterfoils which he handed to witness should have corresponded with those handed to the customers. The counterfoil produced showed that prisoner had received 9s. from a customer, but he had only accounted for 6s. Prosecutor also gave evidence in respect of other items. After a lengthy hearing, the Bench committed the prisoner for trial, but admitted him to bail on his own recognisances.

A PHOTOGRAPHIC Lens Case.—Messrs. Brickell and Jones have

then to us regarding the report published recently in this column the case in which they were defendants, and Messrs. Perken, and Co., Limited, plaintiffs. They mention that the cause of action arose from the fact that, in June last, they published an illustrated photographic catalogue containing blocks illustrating lenses. These blocks had been obtained by request from Messrs. Perken, Son, and Co., and were not intended to be illustrations of the plaintiffs' lenses at all, as the prices quoted were lower than Messrs. Perken, Son, and Co.'s quotations. Messrs. Brickell and Jones, however, did not observe that the plaintiffs' name was on the blocks, and, in reply to a written order for "one R. R. lens as illustrated," the price being enclosed, supplied an ordinary R. R. lens, not Messrs. Perken, Son, and Co.'s make, and it was in respect to this that the action was taken. When their mistake was pointed out by Messrs. Perken's solicitors, they saw they were in the wrong, and removed the page containing the illustrations from their catalogues, and through their solicitors offered to pay 40s. damages, giving an undertaking in the terms of the writ which they had been served.

News and Notes.

THE IPSWICH CAMERA CLUB holds its second photographic exhibition on November 14, 15, and 16. There are five open classes, and a gold medal is offered for the best picture in the show. Entries must be received at the Art Gallery, High Street, Ipswich, by November 9. Entry forms will be supplied on application to the hon. secretary, I. Sutton, 37 Henley Road, Ipswich.

THE DEVELOPMENT OF THE ZOETROPE.—In reference to a statement in the "London Magazine" for July last, to the effect that the improvement on the zoetrope was the zoopraxiscope of Mr. Muybridge, Mr. Thomas Ross sends us the letter which we print in our column and the following notes, of which presumably he is the writer, in the "Cape Times":—"Many minds were bent on the idea of putting the zoetrope into the lantern, and it was not until, when the feat was accomplished by Mr. Thomas Ross, of Glasgow, by means of two revolving discs, one of glass containing the subject, and the other of metal with its thirteen slots or openings according to the principle of the zoetrope. This invention was patented and sold to Messrs. Negretti and Zambra, of London, and was also pirated and published successfully by two different lantern-makers. The great defect of this first invention by Mr. Ross, though strictly correct according to the principles of the zoetrope, was the slowness of the revolving disc with its thirteen slots or openings. As the metal disc only made one revolution for one of the glass disc, the slots were visible on the screen, although the motion was otherwise perfect. To get quit of this defect was necessary to get a perfect result. Another defect was that a thirteen-figure disc showed twenty-six figures on the screen, a defect common to all wheels of life or zoetropes. After a deal of hard study and thinking, Mr. Ross solved the problem successfully by making the disc with one opening equal to all the thirteen put together, and the disc to revolve thirteen times for one of the glass disc containing the subject. This new invention gave thirteen times more motion, and the disc completely disappeared on the screen, while, instead of twenty-six figures, only fourteen appeared, much larger in size and more perfect in motion. This slide was also patented and sold to Messrs. Pumphrey Brothers, of Birmingham. A full description was published in the BRITISH JOURNAL OF PHOTOGRAPHY for the time. This slide was an advance upon all the wheels of life previously published, and has found its way all over the world. Mr. E. J. Muybridge all credit for his trotting horses from a

scientific point of view, without Mr. Ross's invention he could never have exhibited them. Mr. Muybridge's method was never published, and, furthermore, without the invention of the revolving disc by Mr. Thomas Ross there would be no cinematograph or biograph to-day."

THE prospectus of the Sheffield Photographic Society's third annual exhibition, to be held at the Montgomery Hall, Surrey Street, Sheffield, from October 28 to November 4, contains particulars of seven open classes and five members' classes. Plaques are the awards, and the judges will be Messrs. F. M. Sutcliffe and C. Barrow Keene. Full particulars will be supplied by the joint exhibition secretaries, J. W. Charlesworth, 1, Joshua Road, Sheffield, or J. W. Wright, 62 Vale Road, Sheffield.

EFFORTS are being made to secure the St. Louis collection of pictorial photographs now at Rochdale for an exhibition at the Art Gallery, Bolton, from October 14 to November 30. We wonder what the condition of the frames will be when they finally reach their owners.

WAR at the Peace Conference.—From the American papers we learn that the Peace Conference at Portsmouth, U.S.A., had as one of its incidents a cavalry charge, the assailants being not Cossacks or Japs, but a picket of U.S. cavalry, and the vanquished a detachment of the camera brigade. It was stated that many of the photographers were knocked down, and their "boxes" smashed, but there appears to have been no fatalities.

THE death is announced of Mr. Thomas Stearn, head of the firm of that name in Bridge Street, Cambridge. Mr. Stearn was in his eighty-second year at the time of his decease, and had been in business in Cambridge for sixty years.

"IN case the doings of the ubiquitous Tanqueray still interest you," writes a Réunion correspondent to "Truth," "it may amuse you to hear that his free-portrait dodge has reached this forgotten little island in the centre of the Indian Ocean." This certainly does interest me, remarks the editor of our contemporary, for now that the swindler is preying upon French colonists, perhaps the Paris police may at last find a method of bringing him to justice.

ON Friday week the British Association brought its South African meeting to a close in Johannesburg. One of the most gratifying features of the meeting has been the number of papers read on South African subjects, many of them by residents. Such an awakened interest in the less material aspects of the country cannot but have a beneficial effect on scientific and educational development. Professor Darwin referred to this fact in his closing remarks, in which he also declared that the meeting must be considered the most successful in the whole annals of the Association, and thanked the country for the lavish hospitality which had been everywhere extended to members. It was announced that Professor Ray Lankester had been elected President for 1906.

THE Pictorial Selection Committee of the R.P.S. Exhibition are having a week's hard labour from all accounts, and it is to be regretted that only five out of the six good men and true chosen for the work are able to be in attendance. The absentee is Mr. Furlley Lewis, and it goes without saying that his services in this capacity will be sorely missed. He is at present on a bed of sickness, and will be quite unable to get about for some time to come. His many friends in the photographic world wish him a speedy recovery.

MR. F. W. SPEAIGHT, of the New Bond Street Studios, writes from the Constitutional Club, to the "Pall Mall Gazette":—"I have always understood that flags should be hauled down at sunset. Imagine, therefore, my surprise at 7.30 to-night when I noticed the flag still flying over the Admiralty buildings in Whitehall. Perhaps the Lords of the Admiralty mistook the harvest moon for the sun, and were patiently waiting for it to set."

Correspondence.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* * We do not undertake responsibility for the opinions expressed by our correspondents.

RETOUCHING BY NIGHT.

To the Editors.

Gentlemen,—Being a regular reader of your valuable paper, I noticed in your "Answers to Correspondents" page that P. W. Webb would be glad to know of the best light to retouch by after dark, and should be glad to help him in the matter, and may be interesting to your readers. If your correspondent gets the "Bruce" outfit for retouching at night, I think he will find he has got all he wants. I have used it for some long time, having to do my work at night very often, and I can say the light is equally as good as daylight. Gas or electric light is not wanted, ordinary lamp oil being used. The outlay is small, but to me I can say it is worth pounds. Mr. Bruce is doubtless known to your readers.—Yours faithfully,

AN ASSISTANT.

PHOTOGRAPHIC TRADE IN NORTH AFRICA.

To the Editors.

Gentlemen,—I observe in the *BRITISH JOURNAL OF PHOTOGRAPHY*, August 25, 1905 (p. 672), a suggestion that agencies for the sale of British photographic goods should be established abroad. Although I rather doubt the likelihood of manufacturers combining in the manner indicated, I am ready to enter into relations with any of my countrymen with a view to setting up such an agency for Tunisia and Algeria, for which my long practical experience in photography and projection, as well as my acquaintance with these countries and the languages there spoken, peculiarly qualify me.

I need not remind you that these regions are very numerous visited by wealthy tourists, many of whom are amateur photographers.—I remain yours faithfully,

J. WILSON.

Publicité Nocturne,

Porte de France et Rue Al-djazira, No. 1 bis, Tunis, Africa.

September 1, 1905.

[Mr. Wilson appends a list of references and other particulars which we shall be agreeable to handing to any interested parties.—Eds. B.J.P.]

AN ACETYLENE QUERY.

To the Editors.

Gentlemen,—Referring to the inquiry of Mr. J. E. Organ in your number of the 25th inst., we would like to state that, although we are not experts in portrait photography, we get, as the largest British makers of carbide of calcium, a good deal of information on such matters.

If Mr. Organ will communicate with us, we will with pleasure lend him some new incandescent mantles for acetylene, which give roughly three times as much light per cubic foot as the open burners do.

We have not yet tested these mantles in order to ascertain their spectrum, but they seem, judging by the colour, to give a light of higher value for photographic work than the coal-gas mantles, and than the ordinary twin-jet acetylene burners. In all probability they will be found to have the same proportionate value as compared with the twin-jet acetylene flames as is the case with coal-gas—i.e., as 44 to 12 (Vidal's figures).

Anyway, it will cost Mr. Organ very little indeed to make a trial.—Yours faithfully,

THE ALBION PRODUCTS CO., LTD.

11, Queen Victoria Street, London, September 11, 1905.

THE DEVELOPMENT OF THE ZOETROPE.

To the Editors.

Gentlemen,—Mr. Edouard Charles, in his introduction to an interesting article in the "London Magazine" for July on the Bioscope makes the statement that Mr. Muybridge was the first to make any improvement on the zoetrope, but I claim that position for my invention, which was made thirteen years before Mr. Muybridge exhibited his trotting horses in 1882 in London. By referring to your volume for 1869 your readers can verify my statement. When I showed my invention to Mr. Traill Taylor, who was then Editor of the *BRITISH JOURNAL OF PHOTOGRAPHY*, he requested me to write a full description of my invention and the theory of its working, and this I did. As I was for a number of years a lantern-slide maker, I also invented a method of colouring which was also published in the *BRITISH JOURNAL OF PHOTOGRAPHY* in 1876 in a series of articles.—Yours faithfully,

THOMAS ROSS.

Gordon House, Milton Road, Observatory,

Near Cape Town, South Africa, August 23, 1905.

[We can give Mr. Ross the credit for the invention of the lantern zoetrope, or wheel of life, as it was called, which was patented by him in 1869 and 1871, and was the first popular form of moving picture on the screen. Muybridge's instruments were no doubt derived from the first Ross apparatus, though we cannot agree with Mr. Ross that the "wheel of life" with its constantly moving disc is in any sense the progenitor of the cinematograph film, moved forward step by step and kept at rest whilst it is uncovered. Our space will not permit us to enlarge further on the early history of the living picture, but those to whom the subject is of interest may be referred to "Living Pictures," by Henry V. Hopwood. Part of some comments on Mr. Ross's invention from the "Cape Times" are quoted in another column.]

"GUMRIHMEIATE."—We cull the following from "The Federation Record":—"An intelligent compositor, in setting up a report of the Crook Society's "doings" for the winter season, included a lecture on 'Gumrihmeiate.' Bi-Gummers are requested to give the new word their earnest consideration. If they can once 'get their tongues round it' or 'the hang of it' it is most euphonious, and withal pleasing to the eye either in print or ordinary calligraphy."

R.P.S. AFFILIATION MEETING.—On Friday evening, September 29, at 7 o'clock, there will be a special meeting of members of affiliated societies at the R.P.S. exhibition, New Gallery, Regent Street, by kind invitation of the Royal Photographic Society. Admission will be free to members producing their red books. This occasion will again afford members of societies an opportunity of meeting members of other affiliated societies, and also of seeing the R.P.S. exhibition, and it is hoped that a large number will attend, in view of the great success of last year's meeting.

THE prospectus and entry forms for the eighth annual exhibition of the Croydon Camera Club has been published. The exhibition opens on November 8 and closes on November 15. Entries must be delivered at the Horniman Hall, Y.M.C.A., North End, Croydon, on or before October 28. There are six open and five members' classes, and the judges will be Messrs. H. W. Bennett, Reginald Craigie, and J. A. Sinclair. Further particulars will be supplied by the exhibition secretary, W. H. Rogers, 88, Woodville Road, Thornton Heath.

THE death of Mrs. S. W. Fisher, wife of Mr. S. W. Fisher, J.P., of Scarborough, is recorded in the Scarborough papers. The deceased lady, who was well known in the district, was a daughter of the late Mr. Napoleon Sarony, of New York, one of the founders of Sarony and Co., the eminent firm of photographers, with whose English house Mr. Fisher has been long associated.

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

A. Harris, Wesley House, Merthyr Tydfil. *Photograph, Postcard View of the Recreation Ground at Merthyr.*

Ross, Norman Place, Leslie, Fife. *Two Photographs of Part of Lochleven, showing Stitches and Bishop Hill.*

A. Baker, 118, London Road, Southborough, Kent. *Photograph of Old Oak Room interior of the "George and Dragon" Hotel, Speldhurst, Kent.*

R. Protheroe, 30, Wine Street, Bristol. *Two Photographs of the Bristol Rovers Football XI., Season 1905-6.*

C. Macmahon, 27, Academy Street, Inverness, N.B. *Photograph of House Party at Moy Hall, including Prince of Wales.*

E. P. Davies, 26, High Street, Ross, Herefordshire. *Photograph of Two Children in Ragged Attire, taken in the Street.*

W. Ellis, High Street, Sidmouth. *Photograph of the Solar Eclipse, August 30, 1905, 1.10 p.m.*

F. Usherwood, 5, Hounds Gate, Nottingham. *Photograph of Act 3, Drama entitled "Drummed Out."*

Thirlwell, 21, Bridge Road, Stockton-on-Tees. *Two Photographs of "General" Booth.*

T. ARMITAGE CUTLER.—L. Gaumont and Co., Cecil Court, Charing Cross Road, London, W.C.; Hepworth and Co., of the same address; Chas. Urban Trading Company, Rupert Street, London, W.; Warwick Trading Company, Warwick Court, High Holborn, London; and the Prestwich Manufacturing Company, 1, Landsdowne Road, Tottenham, will supply what you require.

EAKEY STUDIO ROOF.—I have had considerable trouble recently by leakages in my studio roof. It is built rather flat, and although I have had it done up repeatedly by local builders, the leakages continue. I should be grateful if you could oblige me as to any preparation likely to answer the purpose better than putty and white-lead paint.—W. J. B.

It is possible that the trouble may arise from the sash bars not being sufficiently rigid, so that they bend under the force of a strong wind? If this be the case, it will be next to impossible to make the roof waterproof, as when the putty gets hard it will crack with the strain. The remedy, if this is the case, is to strengthen the sash bars by having one or more T-iron bars fixed under them, laterally, and screwed to them. Then the old putty should be cleaned away, the rabbets given a coat of paint, and fresh putty, mixed with a little white lead, applied. After that the work should receive a coat or two of good paint. We have heard of tar instead of paint being used for the sash bars with good effect.

ARISTOTYPE.—I should feel greatly obliged if you could tell me if there is a printing paper on the market called "Aristotype," I believe made by the Aristotype Company, Limited. If so,

can you give me the address of same, or address of agents?—S.P.

You evidently refer to "Aristo" paper made by the American Aristotype Company, Limited, and sold in this country by Kodak, Limited, Clerkenwell Road, London, E.C.

CHEMISTRY.—Could you kindly inform me through your paper what chemical action takes place when the developer is poured over an exposed plate, also when the plate is placed in the fixing bath?—C. C. B.

To answer your first question fully would require a series of articles, and involve a good many debatable statements. You should study a book on the subject, such as Townsend's "Chemistry for Photographers" (Dawbarn and Ward, ls.) or Meldola's "Chemistry of Photography" (Macmillan, 6s.). Roughly, the developer reduces to the metallic state the light-affected silver bromide or chloride. The fixing bath dissolves (by conversion into soluble silver thiosulphate) the unaltered bromide or chloride.

COPYRIGHT.—1. Copyright of a photograph, taken in the usual course of business, is, I suppose, after decease of sitter, vested in his heir? 2. In the event of photographer selling prints, etc., after death of sitter, can sitter's heir bring a claim against him if copyright is not registered?—ESMOND.

1. Yes, that is so. 2. A sitter can prevent the sale of copies of his portrait, whether he has registered the copyright in it or not. We should presume that the heirs have a similar right, but we cannot call to mind any case where a legal decision on the point has been given.

N. EVANS.—The fault certainly seems to be with the lens. Are you sure it is always quite clean, and has not a slight film of dust or grease on one of its surfaces? This would give the effect seen in the negative, which appears in all other respects quite correct and free from fog. You do not say what type of lens it is, but careful wiping of the surfaces of the lenses with an old clean soft cambric handkerchief dipped in alcohol will clean off any foreign matter, and a final light polish should be given with a dry part of the cambric.

A. WALKER.—The Rotary Photographic Company, Ltd., New Union Street, Moorfields, E.C.

H. A. M.—It is probably not a gelatine paper, but platinum, or carbon.

J. C. R.—1. The print is a tinted P.O.P., faced with celluloid. 2. Messrs. Dorrett and Martin.

BROMIDES AND GASLIGHT.—1. Will you kindly inform me through the B.J.P. of the best method of developing glossy bromides to avoid dirty skies? 2. Also the best formula for sepia toning bromides? 3. Is there not a good self-toning gaslight postcard on the market, which could be used commercially?—BROMIDE.

1. If you will refer to "New Materials" in this issue you will find a notice of a developer sold specially for the purpose of avoiding markings on glossy bromide and gaslight papers. 2. Bleach the prints in potassium ferricyanide 10 grains, potassium bromide 15 grains, water 1 oz. Wash in frequent changes of water for five minutes and immerse in sodium sulphide 10 grains, water 1 oz. until toned. Then wash well for about a quarter of an hour. 3. There is no self-toning gaslight postcard on the market.

COPYRIGHT.—As a constant reader of your journal, I should be glad if you would inform me how I can find out whether a postcard is copyright, as I have one which I should like to reproduce.

It was bought at Ottawa, and, I believe, produced in Sweden. There is no copyright stamp to be found on it, and I think the card rather clever.—POSTCARD.

The country of production of the card is no help to you. You need to know the country in which the photographer took and registered the photograph. Even with that knowledge it will be difficult for you to find out whether there is copyright in the print; but you will be fairly safe in assuming that there is. In any case, we admire your candour in proposing to take what is not yours.

FOCAL-PLANE SHUTTER.—A customer has asked me the following question, and I shall be glad if you can enlighten me on this point. He wants to know which is the better way of working his focal-plane shutter—whether to work it with the first tension and a certain slot opening for a speed of, say 1.60 sec., or whether to use the second tension and a larger slot, and so get the same speed. Is there any difference?—A. H. D.

In practice the second method will be found the best. The first method is more apt to give distortion.

ARTIFICIAL LIGHT.—As a reader of the B.J.P., I will esteem it a favour if you will answer one or two questions through your "Answers to Correspondents" column. 1. Are any books published on electric and other lighting for portraiture? If so, where obtainable. 2. How many candle-power electric is necessary to obtain best results for single figures and small groups, special rapid plates and fairly quick lens? 3 What is the difference between arc lamps and incandescent lamps? 4. Are those without glass globes any better than those with?—FLASH.

1. "Artistic Lighting," by Jas. Inglis (Dawbarn and Ward, Ltd., 6, Farringdon Avenue, E.C. 2s. 6d.) is the only book, but it does not touch electric light. 2. From 1,000 to 2,000. 3. The incandescent light, produced from a heated carbon filament, has an intensity of only about sixteen to fifty candle-power. The arc light is produced between a pair of carbon rods, and has a candle-power of 1,000 to 2,000. 4. The globe is usually used only to diffuse or protect the light.

COPYRIGHT.—1. I have been given the order to take some photographs, which are paid for in the usual way, and my clients have very kindly offered me the copyright. Would you please give me the necessary wording for an agreement to that effect? 2. It must be witnessed, must it not? 3. Where do I get the 6d. stamp put on you advised a correspondent recently—through the post-office? 4. Will one agreement do, or must I have a separate one for each photograph? 5. Rubbing the plates with chalk before squeegeeing I find very messy, and the prints liable to markings. Can you advise a better method, at the same time certain to strip? 6. What address do I write to for copyright forms?

1. The following form of assignment is recommended to its members by the Professional Photographers' Association:—"To Mr. A. B. In consideration of your this day, I hereby agree that the copyrights in such photographs shall be reserved to you, and that I will not deal in any way with the photographs to prejudice your interest in the copyright." In reference to passage left blank, there must be some consideration, such as reduced charge, even if trifling, and the assignment should be made at or before the time of sitting. 2. It should be witnessed. 3. An agreement stamp from the post-office. 4. Several photographs can be included in one agreement, a list of them sufficient for identification being made. 5. French chalk is the best polishing medium;

but try the following:—Spermaceti wax 20 grains, benzol 1 oz. 6. Stationers' Hall, Ludgate Hill, E.C.

OXYGEN GAS.—I have the opportunity of purchasing an "oxygenator," second-hand. Will you kindly say whether oxygen generated from "oxylith" compares favourably with that compressed in cylinders as regards purity and safety in use, have been wondering whether the chemical used, viz., oxylith has any tendency to attack the metal forming the inner wall of the generator, and in so doing to throw off gaseous fumes likely to contaminate the oxygen. Do you think so?—GENERATOR.

No. We believe the "oxylith" is a peroxide preparation and the evolved oxygen is fully as pure as that supplied in cylinders, for this latter is also made by a peroxide process.

OLD NEGATIVES.—Will you kindly inform me if there are any firms of plate manufacturers, or others, open to purchase old negatives, as I have an accumulation, many of them collodion (wet plates) on patent plate glass, which I should be glad to be rid of? The names and addresses of any reliable firms will much oblige.—B. V. REEVES.

If the subjects are of an attractive character, suitable for window bills, and if they are also suitable for printing on the modern papers, it is possible that one or other of the leading manufacturers would make you an offer for them.

THE SNOB-CRITIC.—There are some folk who are under the impression that the snob has become extinct since the days of William Makepeace Thackeray. Alas! for these hopes. The "Maggie," writing in a contemporary, falls foul of the management of last year's R. P. S. exhibition. "On one occasion," he says, "a very distinguished gentleman *who was only incidentally an amateur* (the italics are our own) appeared in order to lecture. He was dressed 'within an inch of his life,' and was accompanied by a lady who looked like a costly fashion plate." We wonder whether the lady or the gentleman is the better pleased with this description, and how the readers of our contemporary enjoy the distinction drawn between a gentleman and an amateur photographer. The "Maggie" goes on to say that "the room was full of seedy-looking half-pricers and free-passers," and winds up his diatribe by saying that the distinguished guests were, in the absence of the exhibition officials, received by a young man in a tourist's suit. The magpie has long been supposed to be unable to distinguish between his own property and that of others; when gifted with speech he is said to be a perverter of the truth, but now that he uses a pen he reveals himself as a snob *in excelsis*.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

PRELIMINARY ANNOUNCEMENT.

Our forty-fifth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,612 pages, the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued two such unique facts be recorded. The edition for 1906 will also consist of 25,000 copies.

The lines followed in the previous editions of the ALMANAC have been maintained in general, but in a number of particulars the arrangement of the volume for 1906 will be modified to make it more than ever the book of general photographic reference. As in the past, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may be of use to our readers as susceptible of improvement.

The ALMANAC for 1906 will appeal to photographers all over the world as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded, and wherever practicable features of an informative nature will be added.

*** IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1st, as well as in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

EX CATHEDRA.

What Should be the Life of a Silver Print?

At the present time there are more processes, and modifications of them, for the production of silver prints than at any period in the history of photography. One of the chief claims put forward by their different advocates is that with their methods of working them they yield permanent results. In proof of this it is sometimes stated that the prints have lasted two or three years, and show no change. Is that to be taken as a proof that they will not change later on? Theoretically a silver picture is not a stable one, yet we have it in evidence that some silver prints made thirty or forty years—even longer ago than that—are still, to all appearance, as good as on the day they were produced. This may be taken as a proof that silver prints need not be so fugitive as some would have us imagine. If only a single print had stood the test of time for forty or fifty years—and there are some still intact that were made in the very earliest days of photography—there is no reason why every one, if made under the same conditions, should not be equally as permanent. No one will question, we think, that there are more silver prints being produced daily that will in the very near future pass into the "sere and yellow leaf" than there ever was before. But is that the fault of the modern processes producing them, or is it due to those who practise them? We unhesitatingly say to the latter rather than to the former. By far the larger proportion of silver pictures now made are by gelatine emulsion processes. The bromide process, for example, should yield very permanent pictures if worked under the conditions necessary to secure them, but they are too often ignored through ignorance or neglect on the part of the workers. Bromides are frequently toned, and sometimes by methods that are certainly conducive to fugitiveness. But that cannot be charged to the process itself. The gelatino-chloride process, again, should yield stable results if worked with care and judgment, but very frequently it is not; just the reverse. The prints are often very imperfectly fixed. Combined toning and fixing is one very prolific source of instability, not because the method itself is so bad, but because the bath is often used long after it has been exhausted of its gold, and also by reason of the desired tones being sometimes arrived at long before the prints are properly fixed. However, we are pleased to see that the majority of the makers of the P.O.P.s now rightly discourage the use of the combined bath. Collodio-chloride, theoretically, should be, perhaps, the most permanent of all printing-out processes. Yet we frequently hear of the prints breaking out in spots soon after they are finished, this being generally due to their being toned with platinum, and the acid

toning bath not being removed before the prints are put into the fixing bath. Here again it is not the fault of the process, but of its workers.

* * *

Criticisms of Retouching.

As many of our readers are aware, we make a practice of offering criticism of retouching submitted to us for that purpose. This standing offer is constantly accepted by retouchers of all degrees of skill, whence we infer that the help which we are glad to afford proves of assistance to them. But we would draw attention to the fact that such criticism, to be any good at all to the applicant, must be based on a fair variety of work—and work properly finished. In many cases we receive a single untuned and unfixed P.O.P. print, with the request to pass judgment upon the retouching. Criticism under such circumstances is, of course, of very little use. The conditions are not in line with practice, and we therefore beg applicants to observe one or two simple rules in submitting specimens of their work:—The prints should be on glossy P.O.P., properly toned and fixed. Two should be sent from each negative, one before and the other after retouching. The subjects should preferably be varied, so as to display the applicant's ability to adjust his treatment to particular requirements. An excellent selection on which to base useful criticism is the portrait of an aged person, of a young man or woman, and of a child. We are frequently asked to say what salary the work should justify, and though any figure must be misleading in the absence of information as to the worker's personality, etc., it is impossible to give any sort of estimate unless the time taken over a given piece of retouching is stated.

* * *

The R.P.S. Exhibition.

It has not been generally observed that this year's exhibition of the Royal Photographic Society, which was opened yesterday at the New Gallery, Regent Street, W., constitutes a jubilee. Fifty years ago the first exhibition of "The Photographic Society" (it did not attain the dignity of Royal recognition until 1894) was held at the Society of British Artists, under the presidency of Sir Chas. Eastlake, then president of the Royal Academy. Since then the exhibition has been housed in Conduit Street and New Coventry Street, but for the greater part of its history has been assembled at 5a, Pall Mall East, until finally in 1899 the New Gallery was selected as the venue for the show, and it would be difficult to find a more suitable environment for this annual demonstration of the progress of photography. This year's exhibition can be regarded as being of a high standard of general excellence, and representative not only of British pictorial work at its best, but also of the profession and the trade. In most quarters the show will be regarded as one of the finest of the series. The good quality of the pictorial exhibits is undoubtedly due to the rigorous weeding-out process adopted by the Selection Committee. If the honour of being hung at the New Gallery is to be the future incentive to fill the place lately occupied by the defunct R.P.S. Medal, this draconic severity will doubtless serve its purpose. When it is considered, however, that over 2,000 pictures were entered, and only 247 are hung, the effect on next year's entries will be interesting to watch, the chief point to observe being not so much the numbers, but whether the names of certain photographers who have hitherto held aloof from the exhibition because of the Medal will appear in the catalogue. They are not there this year.

Some "Royal" Data.

At the private view of the R.P.S. Exhibition on Wednesday, it was a matter for comment that the quantity of pictures hung at this year's Photographic Salon exceeds that in the Pictorial Section at the New Gallery. Whether this reflects in any way on the respective quality of the two shows is a matter of personal opinion. It is more interesting to compare the number of exhibits at the "Royal" with those of last year's show, and draw conclusions from the general advance in the support rendered in all sections. As we mentioned last week, the number of entries in the Pictorial and Technical Sections exceeded the previous year's total by about 500. In the Pictorial Section only 247 pictures, by 147 exhibitors, are hung, compared with 345 by 207 exhibitors last year, thus pointing to a much higher standard of work. In the Technical Section there are 211 exhibits, including 102 lantern slide entries. In 1904 there were only 164, including twelve lantern slide numbers. Five professional photographers only took space in the last show, but this year there are ten, and their display is of a high order, and very representative. In addition to this, it is satisfactory to note that the trade is represented on this occasion by twenty firms, as against fifteen last year. The presence of the foreign loan collection made the total of American and Continental exhibitors higher at the last exhibition, but otherwise the number of exhibits from abroad averages about the same.

* * *

The Photographic Salon.

Probably few of the professional photographers of London go to the exhibition organised by the members of the Linked Ring. They have seen reproductions of some exhibited picture, or they have been to a previous show and have seen some very bizarre work, and they no doubt imagine visit would mean a waste of both time and money. The exhibition this year contains nothing startlingly extraordinary, and we may also add that there are few pictures which leave a distinct impression of being above the general average. We would urge that a visit be paid to the gallery at 5a, Pall Mall East, though we do not suggest that the portraiture shown is the work all professionals should attempt to produce. Critics must remember, as the forewords in the catalogue suggest, that there are more ways than one—your own—of doing a thing. It should be borne in mind that in several instances the work shown is professional photography. We are sure that if the portraits are examined in a broad-minded spirit valuable lessons may be learned from them, and knowledge assimilated which will be very helpful to the better class professional in his attempt to reach the top.

* * *

Prices at the Salon.

Some of our readers may be interested in the prices affixed to some of the portraits in the Salon. For the large carbon print of Dr. Cleland, Mr. Craig Annan asks four guineas. This picture is somewhere about 20in. by 16in., and if any hand work has been done at all, it is either on the original or reproduced negative or the intermediate transparency. The exhibited print shows no trace of the ordinary "finishing." It is most probable that the effect has been obtained by correct lighting in the studio, though a little work may have been done on the negative to prevent undue prominence of other parts than the face and head. To Mr. Evans' portrait of Mr. Horsley Hinton no price is fixed. This is most probably a direct untouched platinotype from a direct untouched negative, as Mr. Evans believes in pure photography—suitable lighting, suitable exposure, and correct

length of time in development. For his gum-portrait, a print about 7in. by 5in., M. Demachy asks five guineas. The most highly priced picture in the exhibition, however, is a circular print, in appearance something like a carbon print, and about fourteen inches in diameter. The price asked for this work is exactly one hundred pounds sterling. It is doubtful whether the photographic world possesses a Mr. Pierpont Morgan, but if the picture should find a purchaser the Salon committee would make a nice little commission of fifteen pounds. The picture, which is entitled "A Tale of Isolde," is worth studying. It is a portrait group of three female figures, and the arrangement is very reminiscent of many of the late Lord Leighton's fine pieces of composition.

* * *

Suggested Opening of the Ben Nevis Observatory.

In a letter to the *Standard*, last week, a correspondent, Mr. W. Arnold Burgess, directs attention to the closing of the summit and base observatories on Ben Nevis about this time last year for lack of funds to keep them going. He suggests that another effort should now be made, by private subscription, to re-open these establishments before the winter sets in. Of the value of the two observatories, one some 4,400 feet above the other, to meteorological science there can be little question. This country, it is generally admitted, is much behind many others in the matter of meteorology. The Meteorological Council, it is true, receives an annual grant from the Treasury of £15,300, and some time back a committee was appointed to inquire into the expenditure of this sum and report on the subject generally. So far as we are aware very little has come of it up to the present. Out of the £15,300 granted the Council, only £350 was paid towards the support of the Ben Nevis observatories, the remainder being, for the time, provided by a munificent donor. A hundred pounds more, says the writer, was obtained from other sources for keeping it open. Thus £450 was secured towards the £750 required to maintain the observatories. The Meteorological Council will not supply the other £300, hence the observatory has continued closed for the past year. It remains to be seen if Mr. Burgess' appeal will receive the attention it deserves.

* * *

F.R.P.S.

During October the advisory committees, appointed by the council of the Royal Photographic Society to consider applications for the Fellowship, holds one of their two yearly meetings. The Fellowship of the society is open only to members, and is awarded for important contributions to photographic theory, practice, or invention, to pure or applied photography, and in public service in the advancement of photography and dissemination of photographic knowledge. Wide as is this range of qualifications, the council and its committees perform their duties with considerable strictness, and we are in complete accord with their aims to make the letters F.R.P.S. a distinction to anyone associated with photography. We would add that applications are considered by separate sub-committees according as the qualifications are "pictorial" or "scientific" in their character.

The Prince and Princess of Wales have both been photographed preparatory to their tour in India, and an order has also been recently completed by Messrs. Downey, for portraits of the King, which are to be sent out as presents for the native princes. The photograph, for which a special sitting was given at Buckingham Palace, shows his Majesty standing in Field-Marshal's uniform, his left hand resting on the hilt of his sword. The portrait has been reproduced in oils, and also by the three-colour process.

THE POSITION OF PRESS PHOTOGRAPHY.

MUCH has been written about press photography, and the usual line taken has been to advise photographers how to approach editors; and to tell them that very special prices may sometimes be obtained, or that the same picture may be sold "several times over to different editors." Unfortunately the other side of the business is not always dwelt on, and the result is that many men waste time and money, for which there is no reasonable prospect of any return. For press photography is essentially a business, and the man who occasionally submits what he thinks an interesting picture may from time to time make a little pocket-money, but in the aggregate such men stand to lose—the amounts spent in prints and postages totals up more than the half-guineas received by the fortunate ones. Papers which depend largely on one class of work—as the sporting papers—usually employ their own photographers or some firm specialising in their work, and the daily papers which give topical illustrations are doing the same to a greater and greater extent. Then certain names occur to anyone in connection with portraits of theatrical or other celebrities, marine work, etc. These firms have devoted special attention to these lines. Some of them have sunk much capital in assembling a large stock of negatives of eminent people, or in equipping studios for theatrical work. If any prominent person comes to the front for a moment their prints of him are with the editors in a few hours, before the countryman, who has a similar negative, can send his picture through the post. When it comes to speed, the daily papers, who are turning more and more to photography, must have things in time. Saturday's events must be pictured on Monday morning, and this means that the editors must have the prints on Sunday. The press photographer secures his pictures—football or what not—and his negatives are developed and often printed the same evening. The editor receives them on Sunday, and on Monday morning, hours after his paper is selling, the amateurs begin showing their views. Where an event occurs during the week the pictures must, of course, be offered the same evening.

Many photographers fail from their inability to gauge what is of sufficient interest. To quote sport again, during their seasons, cricket and football pictures are always in demand. But a dozen first-class cricket matches take place every week, and half a hundred prominent football matches every Saturday through the winter. As editors cannot present a tithe of these, it is not sufficient to have good photographs in order to make a sale. There are many things, too, which, though of local interest, are of no moment to people in another county, and editors must consider what will interest the largest number of their readers, who are scattered all over the country. A local bazaar, or even the opening of a town hall, may fail of acceptance for this reason. Interest, too, varies with the class of paper. A sixpenny weekly, for instance, seldom takes cognisance of a murder. The portrait of a murderer or his victim may appear as a line sketch in some evening daily or Sunday paper, but beyond this there are only two or three papers in London to which such pictures might be shown.

Journalistic conditions being what they are, the press photographer earns every penny of his money. His efforts are directed to turning out good work speedily. Exposures of one day may have to be delivered the same evening, or, if not, early the following morning. When an event takes place in the country he returns by a night train and at once proceeds to development. Or the negatives are sent by passenger train, which is met by some co-worker, often in the chill, small hours of the morning.

And the prints which are sent out a few hours later must bear no traces of hasty work. The negatives have to be carefully developed, and the prints dry and glossy. But the man has his reward, for his pictures sell. It is interesting to note how often the press photographer scores in events where it would seem that local men or amateurs would have a good chance. Recently a statue was unveiled some 200 miles from London. The event was anticipated, and several London papers asked local men to send them prints. But if the prints reached the editors they came too late to be any good, and the press photographer got the business.

The man who occasionally strays into press work cannot understand why his work is not accepted, when he sees work reproduced which is no better. He overlooks that such work as appears is less than 1 per cent. of the good stuff available. From time to time some paper will give a picture of, say, an interesting church. But there are hundreds of interesting churches in existence which have been photographed, and fifty may have been unsuccessfully submitted to an editor before, for some obscure reason, he accepted the fifty-first. And interest is only relative, and editorial space is limited. When anything of widespread interest happens—it may be the visit of a foreign navy or riots at Baku—pictures of such happenings crowd out other pictures. When all the world is at peace, and a quiet season is on, editors have space in which they can handle the things which are "good enough."

For the dilettante press photographer these are unconsidered trifles. Some men—usually amateurs—have a

very happy knack of picking up odd scenes or happenings which sell because they are interesting. Quaint old customs or old relics occasionally fill a spare corner in a paper. The revenue from this source is largely to be considered as a little pocket money *plus* the pleasure of seeing one's pictures in print. Sometimes a photographer will sell a page of prints in this way, but the field is limited and scarcely worth serious consideration unless a man has the special gift of seeing the right things.

Reference to press photography would not be complete without consideration of the picture postcard. There is still a big output of cards, though the publishers are more stocked with views than they were a few years ago. We constantly receive letters enclosing views in reference to their sale to postcard publishers. Usually the views are quite useless for the purpose. Many postcards are being issued in conjunction with local photographers or stationers, and unless his views are exceptionally good and of some district not yet represented, the photographer may expect disappointment. Postcard publishers are keen buyers, and they will often try to purchase *negatives* at a price below the "usual" half-guinea for a single reproduction.

In conclusion, press photography may be summed up as a highly specialised line of business—one which has but little scope for the average occasional man; and where a man needs to be alert and speedy if he would succeed. It affords a livelihood for a large and increasing number of men, but has little possibility for the man who wants to pick up money easily.

PHOTOGRAPHIC SOCIETIES AND EXHIBITIONS.

SOME NOTES ON THEIR PRESENT POSITION AND MANAGEMENT.

III.

Reporting Society Meetings.

LAST week a reference was made to the necessity for reporting the meetings of photographic societies in the local and photographic press. Not only is this a necessity for the continued well-being of the society, but the influence that this kind of publicity has on the membership is usually very marked. Societies have been known to exist for years in a state of stagnation, holding occasional meetings at which nothing has been done either to further the interests of the society or photography, and outside the little circle of friends nothing is known of its existence. If the object of such a club is photography and the improvement of the photographic knowledge, etc., of its members, steps should be taken by its executive to make its existence known. This will not only bring in new members, who may include useful workers, but the interest of the present members will be quickened by competition and argument with them. Every year we hear of societies becoming defunct, and the cause of their winding up can usually be traced to this state of continued obscurity.

The Need of Publicity.

The members of these societies may argue that so long as their revenue is sufficient to cover expenses, why need they trouble to do anything further? In other words, they have no practical interest in photography, and their society is simply a social club at which they occasionally discuss photography or have a passing desire for investigation aroused by a trade demonstration. They have ceased to emit ideas themselves and have exhausted all the ordinary topics of photography as it appears to them. How changed all this would become by

the introduction of a few "live" members to stir matters up and promote research. This state of things can, however, only come to pass by giving publicity to the affairs of the society, first in the local papers, and then in the photographic press. The doings of the society are chronicled, and when the name of the association is sufficiently well known by constant repetition in print every photographically inclined person in the district who reads the papers will think it is his duty to join. At all events, there will be less difficulty in persuading him to become a member than if he had never heard of the society.

The Wrong Sort of Report.

There are many societies that fully appreciate the necessity for publicity in the press in order to bring them to the front. They have "live" members, good programmes, and an energetic secretary, and more often than not have also a reporter. Yet they are not heard of to the extent they desire or merit. The reason of this is because the wrong sort of reports are submitted to the papers for publication. The editor and the paper itself must be considered when drafting a report of a meeting, and, as mentioned previously, it cannot be expected that valuable space in a photographic or local paper will be filled with information that is of interest to one or two people only. At the same time a certain amount of difference can be made in the reports sent to local papers and to the photographic press. In the first case the names of any prominent local men who may be present can be included and will doubtless be noted by the editor. This serves the double purpose of pleasing the persons named and drawing attention to the

status of the society. The editors of the photographic papers do not, however, want to know who were present at the meetings or anything concerning the formal business of the evening. They want to know about any practical photography that was discussed or demonstrated, and if any new methods of working were put forward. They want information that will be of use and interest to their readers. Something that their readers can read and profit by, which, if successful, becomes a further advertisement for the society sending the report.

An Example.

As an example of the kind of report that might be submitted to a local paper, but *not* to a photographic journal, the following will serve:—

"A highly successful meeting of the Blank Camera Club was held at their comfortable rooms in Nemo Avenue on Wednesday last. Ald. J. Faddy, J.P., was in the chair, and there was a large attendance. Amongst those present were the Rev. Thomas Kitto, M.A., Capt. Hinchcliffe, R.N., and Ebenezer McDougall, Esq., J.P. The Hon. Secretary (Mr. Westbourne Grove) read the minutes of the last meeting, which were duly confirmed and signed. The names of Mr. T. White, of 524, Fenchurch Street, N., Mr. C. Black, of 199, Mornington Alley, W., and Mr. T. C. Green, of Pye Street, S., were submitted for election. The question of the winter programme was discussed and several members expressed their willingness to read papers, and an interesting session is anticipated. Mr. O. Jones then gave a most instructive lecture on 'Bromide Enlarging,' in which he described his own method of working, and dealt with the subject in a manner that called for the warmest encomiums from those present. The whole process was dealt with in a way which prompted the mover of the hearty vote of thanks (Mr. A. Grey) to say that, although he was a novice, he felt that he was almost competent to undertake the making of an enlargement himself, so clear had the instructions been. The vote was carried with acclamation."

Now it is obvious that a report of this kind is worse than useless to the editor of a photographic paper. It makes him angry and say hard things about the society, and the sender of the report, and yet similar reports are being constantly sent in by energetic but misguided secretaries who imagine they have said all there is to say about the meeting. The greater portion of the above report *may* be utilised as a paragraph in the local paper, as it contains matter of local interest, but in the photographic paper—if it is used at all—it will probably become: "Blank Photographic Society.—Mr. O. Jones gave a lecture on 'Bromide Enlarging' before the members of this society on Wednesday last."

The Right Sort of Report.

There is no doubt at all that from every lecture or demonstration given before the members of a photographic society, some crumbs of practical information can be extracted to make an account of the meeting interesting and instructive to readers

of the photographic papers. It is the duty of the reporter to look out for all possible items of this sort and embody them in his report for the photographic press, and to suppress everything immaterial to its general interest.

Here, for example, is a suggestion as to how the foregoing report ought to have been written:—

"The Blank Camera Club.—At a meeting held at their rooms in Nemo Avenue on Wednesday last Mr. O. Jones gave a lecture on 'Bromide Enlarging.' He recommended rough-surface paper in preference to the smooth varieties if the enlargement was larger than whole-plate size, and advised the use of a slow paper and full exposure if good black tones were desired. For enlarging from a quarter-plate of moderate density to 12 by 10, using an anastigmatic lens working at $f/6$, he found that three-quarters of a minute gave a fully exposed print with incandescent gas as the illuminant. With limelight the exposure could be cut down to 4 or 5 seconds. For vignetting, he used a piece of cardboard with a small hole roughly pierced in the centre. This was held about half-way between the lens and the bromide paper during exposure, and moved about with a circular motion, so that the head to be vignettted received the maximum exposure and the parts surrounding it considerably less. Bolting silk stretched over a light frame and used for the purposes of diffusion of detail during enlarging gave the best effect if placed about $\frac{1}{4}$ inch from the surface of the bromide paper. If placed in contact with the paper the "grain" became too pronounced, but suited some subjects. Enlargements larger than whole plate should always be well wetted before development, otherwise markings would occur. The lecturer recommended the following developer for black tones:—Hydroquinone, 30 grains; metol, 8 grains; soda sulphite, $\frac{1}{2}$ oz.; soda carbonate, $\frac{1}{2}$ oz.; 10 per cent. bromide of potassium solution, 20 drops; water, 20 oz. The prints should always be rinsed after development, and then fixed in hypo, 4 oz., water, 20 oz."

There can be no doubt as to which is the report of more general interest if these two examples are compared and the right sort will take probably less time to prepare if the lecture has been carefully followed, and a note or two made. In any case, there is far more likelihood of the editor inserting the whole of the second example than inserting a very brief reference to the first specimen, which was copied with only slight alterations from one of many such reports sent to the *BRITISH JOURNAL OF PHOTOGRAPHY*.

As mentioned in a previous article, the post of reporter is not a very difficult one to fill, and a little practice only is needed to produce the right kind of report. A knowledge of shorthand is not necessary, and in most cases the lecturer will be only too pleased to verify the formulæ jotted down in the reporter's note book. Further remarks on this question of correctly reporting society demonstrations and also preparing notices of exhibitions will be given next week.

HON. SEC.

GOERZ Lectures Free to Photographic Societies.—The firm of Goerz announces a series of lectures and slides that have been prepared for photographic societies. They include lectures entitled: "Stereoscopic Photography," "The Photographic Lens," "What Can be Done with a Hand Camera," and "Tele-Photography." Full particulars will be sent on application to 4 and 5, Holborn Circus, London, E.C.

THE prospectus of the Hackney Photographic Society's seventeenth annual exhibition announces six open classes and six members' classes. The exhibition opens November 1 for four days, and entries are due on October 16. Exhibits must be delivered at the King's Hall, Hackney Baths, N.E., not earlier than Friday October 27, nor later than Monday, October 30. Silver and bronze plaques are the

awards. A silver medal is offered for the best trade exhibit, and another for the most useful photographic novelty exhibited. Arrangements will again be made for the collection without additional charge of exhibits from the R.P.S. and Salon exhibitions, and in addition, this year free conveyance from Hackney is offered by the Southern Exhibitions to all exhibits entered for the Southampton, Hove, and Southsea exhibitions, if properly packed for transit. We are pleased to note this step in the direction of co-operation among provincial exhibitions. We have on more than one occasion recently advocated this system, and hope in time to see it still further extended. The hon. sec. of the Hackney Society is Mr. Walter Selfe, 70, Paragon Road, Hackney, N.E., and he will supply all further information.

THE WEEK IN HISTORY.

The Enlarger of Forty-eight Years Ago.

On September 22, in the year 1857, the enlarging apparatus long known as Woodward's was patented in this country. Mr. Woodward was an American, but his design of camera for direct enlarging became universally adopted. The Woodward solar enlarger, as it was long known, consists essentially of a camera with a lens of large diameter and a reflector in the rear of the objective, so that it can be used for projection as well as for the reception of an image. The "enlarger" consisted of a wooden body to the front of which a portrait lens was fixed. Immediately inside was a sliding chamber, at the rear of which was the framework (at the focal distance of the lens) for carrying the negative or sensitive plate, as the case might be. Further to the rear, at the open end of the outside body, was a plano-convex lens, adjustable by rack in relation to the negative, and behind it, at a suitable angle, the flat mirror. "The instrument being so adjusted, with the reflector passing through an aperture in the shutter and the room darkened, the sun's rays are reflected with great power through the negative, which is focussed on the sensitised paper, or canvas, of any desired size by moving the inner sliding box and achromatic lens. The image is then printed on the sensitive surface, and it is afterwards to be developed and fixed in the usual way. In using the instrument to reflect a positive picture for tracing, etc., the negative picture is first taken on glass, and afterwards copied in a similar manner by placing it between the instrument and the light, to produce a picture on glass that is positive when seen by the transmitted light, which is then placed in the open sheath at a suitable distance from the luminating lens, when the rays of light passing through it and the achromatic lens, throw a positive picture on the canvas, which, as in the former case, may be arranged and focussed in any desired size to be traced or painted." This primitive enlarging appliance led the way to a number of other types, and readers of the old text-books such as Monckhoven's "Photographic Optics," will see the shifts to which photographers were put in enlarging, until gelatino-bromide paper inaugurated a new order of things.

Woodburytype.

"Process" reproduction is often talked of to-day as though photography applied to the multiplication of pictures were a thing of the twentieth century. As my readers know, the work of Niepce was, strictly speaking, in "process" rather than photography, and Niepce did, as a matter of fact, work out a crude process of photo-engraving. In point of rapidity and fecundity the photo-mechanical process is modern, but it is yet a fact that perhaps the most beautiful of all photo-mechanical processes—in certain respects, certainly the most perfect of all—will be exactly forty-one years old to-morrow. It was on September 23, 1864, that the late W. B. Woodbury patented the process known afterwards as Woodburytype. Unlike other photo-mechanical processes, the print to be reproduced is not broken up by a screen or grain, the full tone of the original is preserved, and a good Woodburytype reproduction of a silver print is practically indistinguishable from the latter except on close examination. Perfect as it was in this way, Woodburytype fell out of use in competition with more rapid methods, for it is of necessity slow—each print has to be mounted—and it suffers from another drawback, that the clear skies and other almost white areas of any size in the prints reproduce dirty unless cleaned up by hand. Hence Woodburytype has gone to the wall against the blows of more commercial processes, and it was not so long ago that you could have picked up a plant for the process in London for very little. Beautiful as the work is, only one firm, I believe, is now producing it. In case that the process itself may be unknown to some readers, I would briefly explain that a bichromated gelatine film is employed on which to obtain a reproduction relief of the negative. This relief Woodbury sought to apply to the preparation of a printing surface by various methods, such as electro-deposition, but in vain, until he lighted upon the fact that the gelatine relief when dried was hard enough to be pressed into lead forming a mould. Such a mould having been produced, the impressions were obtained from it by taking cast after cast in pigmented gelatine.

HISTORICUS.

THE CONVENTION OF THE PHOTOGRAPHERS' ASSOCIATION OF AMERICA.

FOLLOWING on our report last week of the discussion on reception-room tactics undertaken at one of the Sessions of the Photographers' Association of America, we now present a further paper communicated to the Convention, and dealing more particularly with the business side of the photographer's establishment. For the text of the lecture and of the discussion we are indebted to the very lengthy report of the whole proceedings in our New York contemporary, "Wilson's Photographic Magazine."

THE FINANCIAL SIDE OF OUR PROFESSION.

(A paper read before the Convention of the Photographers' Association of America.)

Coming from the West I was sitting with a travelling man, who asked me where I was going. I told him, and he said, "I want to ask you why photographers are such poor business men, and why classed among the poor business men of the country. You have told me there is quite a profit in making pictures, that the actual cost of the material is very little—why cannot you make it a success?" I told him the reason is that the photographer does not give the time and attention to this side of the business he does to the professional side.

I was talking to a stockdealer not long ago, and he told me that 90 per cent. of the photographers of the country were worth less

than \$500.00; that a large per cent. had to receive their goods C. O. D., and there were quite a number who could not buy goods unless the money accompanied the order. That makes me think we are seriously lame on the financial side of our business, because we cannot give it the attention it requires. Most of us are pretty good in making pictures, but where we lack is on the financial side, and if you will pay more attention to that you will find yourselves better off at the end of the year.

Now, I believe to be successful in the photograph business the essential thing is to have a first-class studio—the best in your town, whether it be in the city or outside. Have it as good as your com-

petitors. Americans like to have things nice, and patronise people who can afford to have nice things, so if you have a nice place, half the battle is won.

The Receptionist Again.

The next essential is your reception-room girl. You want to bestow a good deal of care in selecting her; she is the one who makes your success or failure, and she will earn her salary two-fold if you pay attention to getting just the right sort of girl.

I want to tell you a story which I think fits this point. You know the Jews are great business men, and if we should follow many of their tactics we would be more successful. Well, there was a Jew who advertised for a varnish salesman, and a very nice gentleman answered the advertisement. The Jew says to him, "Well, my friend, what do you want?" He replies, "I would like to get this position as salesman." "Well, have you ever travelled on the road?" The applicant said he had a great deal. "My friend, do you think you could sell varnish?" He said he thought he could. "Do you think you could sell varnish to a man who didn't want varnish?" The man replied "I don't think I could do that." "Then get out of here; we don't want you; anybody can sell varnish to a man who wants it."

A good reception-room girl that can sell to people who don't want to buy—the good-looking, up-to-date, wide-awake, intelligent girl, who knows everybody, is pleasant to everybody, and accommodating—she will make the business for you.

Business in the Studio.

Now, then, the operating-room. Of course you may have the capable girl to bring in the business, but you must "make good" in the operating-room. As Lincoln said, you can fool a part of the people a part of the time, but you cannot fool all the people all the time. So in the operating-room you have to back-up with good work the efforts of your reception-girl. You must be in touch with each other.

For instance, a gentleman comes in and says he doesn't want a picture, but his lodge or some newspaper wants it for a cut. Get out the picture he wants, and then say to him, "How would you like a few for your family, or an 8 x 10 or 11 x 14? Those clothes will photograph all right." You will find nine times out of ten that you will be able to sell the man a picture for his friends at home. That is the business side of it. Have your photographer pay due attention to lighting, posing, etc., to individualising your pictures, which can only be done by careful study. After you get a subject to sit for his picture, if you see something that will improve the situation, try it. Don't be stingy with your plates.

Advertise!

I also want to say a word about advertising. Some photographers think they do not need to advertise. That is not so. I have been in business in a little town of 15,000 or 20,000 people for twenty-five years, and been on the road for twelve years. There is advertising and advertising, and every man will find which pays him in the end. For instance, you may hire some smart young man or lady to go from door to door as your representative, not as a ticket-seller, or any cheap scheme, but with a nice line of samples. Let her talk about what a wonderful man "Holloway is," and that he makes pictures for "as high as \$100 a dozen." That is the kind of advertising that sticks. You can get a good many girls in the towns or small cities at five dollars a week, and if she will bring you in one sitting a day it will pay you; and if two sittings a day you can afford to pay her more money. She will do you good.

This same girl can take care of your prospective sitters. She finds that Mrs. Brown is not ready now, but her daughter is going to graduate or receive her first communion, and later on your repre-

sentative can call, and remind her that "Holloway (for example) is making something new, and that he would be pleased to have her call in at any time." That is the way to build up business, and doing it in a square and legitimate way.

A Town Traveller for Photographers.

How many of us pay attention to the outside business that can be gotten in our town? I believe it would pay every photographer to hire an outside man to look after that business. Every town has its factories, which contain men who would like to see pictures of themselves or their associates. By using a little tact you can see them as they come out at noon, not detain them long, and make a picture on the prospect. Those pictures can be sold at from fifty to seventy-five cents, and orders will follow. That is outside business. When I first went to Vincennes we photographed the schools. I was looking out for extra business, and we went to the superintendent and explained to him that we would like to make pictures of all the children in the city. We said that lots of poor people never have the opportunity to have pictures, and we would take only five minutes to a room, and make the pictures cheaply, and enable all to have them, thereby benefiting the poor children of the schools. I made 1,900 pictures for the schools of Vincennes, and, not only that, but I got more calls from those 1,900 pictures since then; I possibly have made 25 enlargements of children who have died, and who had no other pictures; and we have made many copies from those pictures. That is looking after the financial side of the business, which an outside man can do.

The Miscellaneous Commissions.

Every town has a certain amount of commercial work to look after. The way to do that is to tell people that you do it. Have your man go out and say, "We are making pictures of your merchandise, and can save you money. We will make them at the same price that you have been paying outside."

Then there is the man who builds a house and wants a nice picture of it. He will pay you a dollar for such a picture, and that sort of business you can get by simply going for it. Your outside man can also work up flash-light groups—weddings, lodges, etc., which your outside man can bring in during the evening. With the aristo lamp, if you can get ten extra pictures in a year, you have made 10 per cent. on your investment.

The Best Citizen.

Another word—the social side. I believe that every photographer should make himself felt as a citizen in his community, as a good citizen. He ought to take enough interest to go out and vote. Lots of men say, "I don't care anything about politics," but the man who doesn't take any interest in home affairs cannot amount to much. I believe every man should belong to some lodge in his town. Take an interest in the things about you and then people will take an interest in you, and it won't be long before they will say, "There is a good, energetic photographer, and the only one we have had in our town." See that your daughters and wives entertain and go to entertainments; it makes you social, and that brings you business. Don't go back in some little bit of a house and be too stingy to have a little outside popular amusements, for it will come to you two-fold if you go out. That is the way you can make yourselves felt, by being a part of the community in which you live.

The Cost of Production.

Now I have a memorandum here. How many can tell what a dozen pictures cost for the last year—to get them out? What? Just simply the cost? You haven't given it any thought? I believe it is important to take care of your business, though it may be small—to know just what it costs to do business.

I remember when I first went into business I had a pretty good

rating among the stock men, and flew a little high. The first I knew I was a thousand dollars in debt—before I knew it. If I had kept a strict account of cash it would not have happened. Of course I waked up, and to-day we keep a careful account of everything. The reception-room girl takes care of the cash, and if out twenty-five cents she has got to find it.

Keep a good set of books, not only cash, but stock, and systemise

your business. Go out socially; be felt in the community; be a good citizen; do unto others as you would have them do to you, and you will be successful. And at the last, when you turn from this earthly career, and are enwrapped in the great cloak of eternity let it be said by your children's children that you have made pictures that have lived, and at the same time you have been successful in a financial way.

E. E. SHORES.

In the course of the discussion of Mr. Shores' paper the following views were expressed by the speakers:—

Mr. Barrows: I would like also to call your attention to a little matter of advertising, something that Mr. Shores has touched upon—a little advertising I am doing. My method is this—it is something like the clock you saw in the exhibit. The pictures are from children; it is photography pure and simple, brought together in a scheme of advertising. That clock after we are through here will appear in our Boston stores and windows. I expect every person will step up and talk about me—I expect to have half of Boston talking "Barrows."

All of you can do it. That clock has taken a year's time to experiment with those little children and bring them up to that standard. It was made large first and reduced to this size, and I expect later to have it in the original size. It is simply an advertising medium for myself. You can think it over, and devise schemes for yourselves.

Another means are little circulars which I send out. I have attracted the attention of such men as Mr. Strauss, Mr. Sperry, Mr. Barney, as well as W. I. Scandlin, the advertiser, who have used some of my ideas in perfecting their work.

In advertising, when you can reach your people through some medium that will gain their attention for a few moments you have that person with you. And don't stop with the first announcement. After reaching that person once get at him two or three times afterwards; after making him a customer see to it he is made your friend. You can save five out of eight people possibly—I might say you could save six out of eight who come to you. No photographer was ever yet born who could please everybody; be pleasant even though they offend you—be pleasant all the time. I am not infallible, but I believe I can keep as many people after I get them as anybody can.

The matter of proofs. Now, I am a very independent photographer. I try to treat people as honestly as I know how, but I have set rules for conducting my business. One of these is the proof question. I feel that my people do not take offence at my action. I show many proofs, and I sell many pictures from those proofs; but I say on the back of these proofs that they are the property of the Barrows Studio, and they must be returned. We follow it up rigidly, and if once or twice we offend they generally see the force of our reasoning and position. Those proofs we send out, but we require them to be returned or charge for them.

Frequently a person comes into our studio and says, "I would like a half-dozen pictures, but would like to keep the proofs," to which I reply, "Those will cost you as much as the finished pictures. We file them away." Only last week a lady came into one of my

studios with tears in her eyes. "Mr. Barrow, have you the proofs of my little girl?" In half an hour I had found them and got a \$30 order from that lady.

If you are to be a business man why should the community rule you? You have your products for sale; now sell them, don't give them away. You go into the operating-room, take your subject, work hard hour after hour to make your plates; you submit your work, and if you do not secure yourself, at the end of the year where are you? You are simply furnishing material on top of considerable labour, and when you are through the public has got the best of you by hundreds of dollars.

Mr. Sperry: Let me offer you a suggestion about proofs. I do the same way, only I take each proof—as many as fifteen sometimes—and mount each one on a separate slip—just the stock you use in making a folder; then put in an outside enclosure and fasten together with a clasp; and on that outside slip I write the name of the sitter. It is merely a memorandum which is put away on file. On the inside of the cover is suggested who they are, and to send them back.

Mr. Barrows (continuing): That is a very nice plan to follow. Mr. Bridges to-day is taking scrap paper from his folders, trimming it in a certain size for cabinet proofs, in various colours, and printing it for your outside folder, which when you pin it together with the proofs attached makes a complete little album of proofs that is very pretty. He will also print on the face of those proofs any little matter that you want additional. I think he charges you \$5.00 a thousand for the outside folder, and \$2.00 a thousand for the inserts. If you order 5,000 of the outside leaves you would need 10,000 of the inside slips, which would cost you \$20.00 and the outside \$5.00. Thereby you could wait on your customers in the most polite and genial way for \$20.00 in showing your proofs, and go to Bridges and tell him I told you about it.

I believe that we as photographers, if we would talk less about art, less about how we should condense the light upon our subjects, less about many of the technical things, and pay more strict attention to getting before our subjects that which pleases them—instead of fussing over some of these little doctrines as we do—about negatives and plates, to please ourselves, we would draw the public better to us than by asserting our rights, or by pressing upon the public pictures we like but they do not. We should follow more the inclinations of our patrons, at the same time doing good work as long as we can do it—doing it in the way our people like rather than catering to our own whims. Then you will hold your trade more to yourself and longer live in your respective communities as the leading man.

LADY photographers who can turn out good work have never to lament an empty studio, says "London Opinion." But it must be good work, and this depends on the presence of artistic faculty—a faculty which women possess in a higher degree than men. It has been well said that "photography is now almost a fine art. It means something more than simply turning the camera on a sitter, and 'taking' him just as he is, with all his drawbacks thick upon him. The artist immediately sees the best in his (or her) subject, and knows

how to bring it out. Make your patrons think well of themselves. That's what makes some persons get on where all others find the road stony. They have a way of increasing the self-respect of everyone they encounter. It is a beautiful and benevolent art."

THE third annual exhibition of the Northcote Camera Club will be held in the St. Michael's schoolroom, Northcote Road, Walthamstow, on October 11 and 12. There are three open classes. H. Clifford Bennett, 26, Granville Road, Walthamstow, is the hon. sec.

THE PINATYPE PROCESS OF COLOUR PHOTOGRAPHY.

exhibition of the Royal Photographic Society which opened at the New Gallery, Regent Street, there is demonstrated for the first time in this country the process of colour photography invented by Dr. König, of Messrs. Meister, Lucius, and Brüning, of Berlin. The process which was briefly outlined in our last issue is designated "Pinatype," and will be seen to resemble the process of Charles Cros, patented in 1880, and that of Sanger and Sanger, introduced in January, 1903. "Pinatype," as a distinct process, commences after the three colour-sensation negatives have been made. The following working instructions, abstracted from a booklet just issued by Messrs. Meister, Lucius, and Brüning, will give an idea of the operations concerned in the production of the transparencies:—

The Theory of Pinatype.

In the bichromated gelatine plate be exposed to light under a photographic negative, the gelatine, as is well known, is hardened at the parts exposed to the action of the light—that is to say, it becomes insoluble in water to a greater or less extent. If the unexposed gelatine still contained in the gelatine layer is removed by washing, a picture is obtained, only visible to a slight extent, consisting of hardened and unhardened portions.

Pinatype dyes have, however, the property of dyeing the unhardened gelatine very strongly, whereas the hardened portions are not at all or very slightly coloured. Therefore, if moistened with specially prepared gelatine is brought into intimate contact with the gelatine layer coloured by means of a Pinatype negative, in a short time a coloured paper picture with all the half-tones is obtained, which appears most strongly coloured on those parts not affected by light, whilst the most exposed parts remain white. From this it is evident, that in order to obtain a positive image, the bichromate gelatine layer must be exposed under a positive transparency.

The printing of the picture on paper from the exposed and coloured gelatine can be repeated as often as desired.

The Negatives.

As already mentioned, the negatives are not suitable for Pinatype unless special conditions are observed; they should be full of detail and not too hard, so that good transparencies may be prepared from them.

Whilst the preparation of the transparencies involves only a slight modification of the method when copies are required of the size of the original negative, the preparation of enlarged pictures is very greatly facilitated by the necessity of employing transparencies. The negatives can be enlarged direct, and thereby all the details are better preserved than when an enlarged negative has to be prepared from the original negative.

The facility with which enlarged copies can be made is especially important for three-colour photography, as the direct production of enlarged plates in three colours offers many technical difficulties.

The Transparencies.

The three partial negatives have been properly exposed and developed, and therefore completely uniform, the transparencies are then printed and developed simultaneously, or at any rate the time occupied in the operation.

Slight differences in component negatives may, however, be compensated for by slight alterations in the times for exposure for the transparencies; a white object affords the best guide for the fitness of the component transparency. This white object should have exactly the same appearance on all three transparencies, whilst the black parts should in all cases possess the same depth.¹

¹ It is advisable in most cases to make the transparency corresponding to the blue filter negative a little more vigorous than the others.

The pyrocatechine developer is particularly recommended for the preparation of transparencies:—

SOLUTION I.

Pyrocatechine	11 grammes.
Sodium, sulphite, anhydrous	25 grammes.
Water	500 grammes.

SOLUTION II.

Potassium carbonate	60 grammes.
Water	500 grammes.

For use, 50 c.c. of Solution I, 50 c.c. of Solution II, and 50 c.c. of water are mixed together.

For the preparation of large transparencies of uniform degree of enlargement, the cheap daylight enlargers, which usually only admit of one enlargement and stand very firm, are specially suitable.

The transparencies should be vigorous and full of detail, having the character of good lantern slides, rather too soft than too hard.

The Preparation of Copies.

Sensitising Bath.

Chrome salt, 2 grammes (equals two tablets).

Water, 110 c.c.

The chrome salt is either dissolved in a little hot water and then diluted with cold water to 110 c.c. or the entire quantity of cold water is poured over the chrome salt and frequently stirred until all has been dissolved.

The "printing plates for Pinatype" (insensitive to light) are steeped with the film side uppermost for three or four minutes in the above sensitising solution in shaded daylight or lamplight. The solution must not be warmer than 70 deg. F. Any bubbles of air should be removed with the finger or a brush. A great number of plates may be sensitised one after another in one bath, but it is not advisable to reserve the solution employed for future use. After the plates have been sensitised they are well drained and dried in a dark and not too warm place free from dust.

The sensitised plates keep much longer than sensitised pigment paper; they preserve their qualities completely for two or three weeks' printing.

Printing.

The transparencies to be printed are laid in a frame, with the film side in contact with the film side of a sensitised printing plate. The frame is then closed with a good spring and exposed, the exposure being preferably regulated by means of a photometer. Strips of "transfer paper" which have been sensitised in the above bichromate solution exactly in the same way as the printing plates serve usefully as photometer-paper.

If transparencies which are to be printed are always prepared as nearly as possible of the same density (which naturally is much more easy to accomplish with transparencies than with negatives), the times necessary for exposure do not vary very much, being for normal clear transparencies about 16 deg. Vogel's scale photometer. In order to give those who do not employ a Vogel's photometer an approximate idea of the time of exposure, we would mention that the exposure for a printing plate is about the same as for a piece of collodion paper.

Electric arc light is just as good as direct sunlight for printing.

After printing the picture should be distinctly seen in brown colour on a yellow background. The printing plate is now washed in running water, or the water frequently changed, until all undecomposed bichromate has been removed. The finish is easiest to recognise if the plate is taken out of the water and allowed to drip upon white paper; the drips should no longer be yellowish. Usually washing is complete in ten minutes. The plates, which, of course, are no longer sensitive to light, may now be dried or placed direct in the dye solution.

As the picture at this stage scarcely remains visible, it is advisable to adopt some means of identifying the printing plates in three-colour photography, in order to avoid mistakes in the after operations.

Preparation of the Blue Picture.

Dye Bath.²

Pinatype blue, 5 grammes (equals ten tablets).

Water, 250 c.cs.

The bath is prepared some time before use, solution being effected by frequent stirring.

The well-washed printing plate, either dry or moist, which corresponds to the red filter negative is steeped in the blue dye solution and the dish rocked from time to time. The first dyeing occupies about fifteen minutes. The plate is then washed and rinsed until the water running off from it is no longer coloured. It should have the appearance of a transparency full of detail, with almost transparent whites and intense shades. If the whites are too strongly coloured the gelatine on those parts cannot have been sufficiently hardened—that is to say, the plate received insufficient exposure. On the other hand, if the transparency appears hard and without details in the whites, over-exposure has taken place.

If the printed plate is successful, a piece of "transfer paper" of the size of the printed plate is now softened in cold water, any air bubbles being removed,³ until the paper has become completely pliable and fully distended. The paper is now attached to the plate, preferably under water, with the film side against the film side of the printed plate, and both removed from the bath, at the same time draining off the principal excess of water by a gentle motion of the hand. By so doing the operator may convince himself that no air bubbles are enclosed between the plate and the paper.

This having been done, the plate is laid upon a table (paper uppermost) and protected with a piece of oiled silk or the like, and the paper firmly smoothed over with a rubber squeegee,⁴ from the middle outwards, using moderate pressure. This operation is similar to that in the pigment process. If the paper shows creases on the plate after a short time, it has not been soaked sufficiently long; if it is smooth and slips upon the plate, it has been soaked too long. A little experience soon teaches the operator to select the correct mean.

When the paper adheres satisfactorily it is covered with a damp sheet and a glass plate, in order to prevent evaporation, and the whole allowed to stand for ten to fifteen minutes, if desired, under a light weight. By carefully raising the corner of the paper the operator may inform himself of the progress of the printing. If the picture does not appear sufficiently strong the raised corner must be again pressed down. After the lapse of the above period the picture will be found transferred to the paper with sufficient strength. The paper is now removed and hung up to dry.

The printing plate is now again placed for about five minutes in the dye bath, rinsed, and the picture again transferred to paper as above directed. These operations may be repeated as often as desired. Besides time, the temperature is often an influential factor in the transfer of the picture. At higher temperatures the transfer to paper is more quickly made. If the temperature is kept fairly constant (60 to 70 deg. F.), and notice is taken of the time required for "printing" from a certain plate, it is quite easy to prepare a large number of copies exactly alike by simply keeping to the same times.

(²) The dye baths all keep for any length of time, and can be used over and over again.

(³) White spots in the finished picture show that either bubbles have been present or the rubber squeegee has not been applied with sufficient firmness.

(⁴) The squeegee, consisting of strips of rubber set in a wooden frame, as usually employed by photographic reproducers, are most suitable. Rollers are not so well suited for our purposes.

By repeated immersion in the dye-bath the printing plate becomes darker. Even the original high lights colour more and more become the dye solution gradually penetrates below the hardened surface to the unhardened gelatine. Nevertheless, the prints from the plate are quite uniform, as only the exterior surface of the dyed plate has an action on the paper.

The dye plates may be kept for any length of time after use, and can at any time be again employed for the preparation of prints after a fresh immersion in the dye bath.

Preparation of the Red Picture.

Dye bath, 5 grammes (equals ten tablets) Pinatype red are stirred with a little water to a paste, and then 3 to 5 c.c. concentrated ammonia solution added. If the ordinary commercial ammonia be employed, about 8 to 10 c.c. are necessary. But, at this rate, sufficient must be used to completely dissolve the dye to a deep red liquid. A slight excess of ammonia is not deleterious. After about five minutes the ammoniacal solution is diluted with water to 250 c.c. Should the dye-bath become somewhat turbid after long use, it may be immediately cleared and made efficient again by the addition of some ammonia.

The dyeing of the printing plate corresponding to the green-filter negative is carried out in the same manner as with the blue film. The exposure for the red print plate may be given a little longer time than for the blue plate.

After the red plate has been washed with particular care free from the excess of dyestuff, the blue picture, which has been previously dried,⁵ is softened in water and laid under water upon the red-print plate. The operation is carried out in the same way as described for the blue-picture, the blue picture being easily shifted under water so as to completely correspond to the red-print plate. The adjustment must, however, be carried out as quickly as possible so that the red dyestuff shall have no opportunity of being transferred to the blue picture until the adjustment is complete. The exact correspondence of parts, especially in small pictures, may be controlled by means of a magnifying glass. In order to isolate the film of the printing plate and of the blue picture from each other during adjustment, a thin celluloid film may be laid between, about 5 mm. from the edge of the plate. When the adjustment is complete, the paper is held firmly against the plate with suitable clamps, leaving the film free, the film then withdrawn, water again run over the plate, and then the paper pressed firmly down with the squeegee. As directed for the blue picture, the whole is allowed to stand for ten to fifteen minutes, and the paper then removed from the plate.

For each subsequent immersion of the red-print plate in the dye bath about three to five minutes are required.

Preparation of the Yellow Picture.

Dye-bath, 5 grammes (equals ten tablets) Pinatype yellow are placed in 200 c.c. hot water. The solution is assisted by frequent shaking or stirring. The dye-bath keeps well, but has the property of becoming somewhat slimy after long standing. About thirty minutes should be allowed for the first immersion in the dye-bath of the print plate corresponding to the blue-filter negative; for subsequent immersions five to ten minutes. The yellow transfer upon the blue and red picture occupies about thirty minutes. It is therefore, not necessary in this case to make use of an intermediate celluloid film during adjustment, but it is advisable to well moisten the superimposed damp sheet in order to prevent the films adhering to each other.

Assembling the Monochrome.

To increase the picture's fastness to light, which is already con-

(⁵) It is not absolutely necessary that the blue picture should be previously dried.

siderable, and to harden the gelatine layer, the paper is now immersed for about one to two minutes in the following fixing bath:

Fixature, 2 grammes (equals one spoonful).
Water, 100 c.cs.

After fixing, the picture is washed for about five minutes in clean water and hung up to dry.

Sequence of Prints.

Instead of commencing with the blue print, as we have done, and then following with the red and yellow prints, three-colour pictures may also be produced by the following sequence of prints:—

Blue, yellow, red, or
Red, blue, yellow.

It is advisable, however, not to adopt any other order, as the adjustment is thereby rendered much more difficult, even if special aids are made use of for ensuring coincidence of the prints.

Reducing Too Vigorous Copies.

Copies which have been printed too strongly in one or more colours but have not been fixed may be reduced by moistening them and pressing them down on a moist gelatine plate or gelatine paper just as if making a Pinatype print. For this purpose old rejected dry plates may be used; old negatives are not suitable. The longer the paper picture is allowed to remain in contact with the gelatine plate, the stronger is the impression transferred to the plate and consequently the greater the reduction.

Intensification of Weak Copies.

Copies which are too feeble and have not yet been fixed may be most easily intensified by relaying on the requisite printing plate.

Retouching.

Individual parts of the complete picture which do not exactly correspond to the natural colours may be very easily improved before fixing if the operator goes over the picture with a brush dipped in an extremely diluted dye solution. In retouching the picture should always be moist.

Pinatypes, just like pictures prepared on gelatine-silver chloride paper, can, by squeegeeing on a matt or polished surface, be given a matt or enamelled appearance.

The Principal Advantages of Pinatype.

1. The printing plates, which are prepared in a simple manner with the aid of light, allow the preparation of a large number of paper copies therefrom by a purely mechanical process without further resource to light. The print plates can be kept, and at any time used again without the aid of light for the preparation of paper copies.

2. In consequence of the intensity of the Pinatype dyestuffs and the small number of spoilt pictures, Pinatypes are very cheap.

3. Pinatypes are extremely fast to light.

4. A three-coloured Pinatype is not composed of different films. A single thin film carries the whole of the colours, which therefore blend together in an excellent manner.

THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

FIRST NOTICE.

THE Fiftieth Annual Exhibition of the Royal Photographic Society was inaugurated at the New Gallery, Regent Street, London, on Wednesday last, with a private view and soiree. The attendance at both the afternoon and evening functions was large, and included a great number of notabilities in the photographic world. The president of the Society, Major-General J. Waterhouse, I.A., received the guests in the evening, and amongst those present were:—Messrs. J. C. S. Mummery, H. Snowden Ward, A. W. W. Bartlett, Frederick Hollyer, H. Wilmes, W. E. Downey, W. P. Downey, W. T. Greatbatch, Mr. and Mrs. E. J. Humphery, John J. Veizey, Alfred Ellis, Oliver Pike, B. Gay Wilkinson, J. C. Warburg, Frank Turner, C. Welborne Piper, Richard Kerr, F.R.A.S., T. E. Freshwater, Arthur Marshall, A. A. K. Tallent, Bernard Alfieri, S. Herbert Fry, F. A. Bridge and Mrs. Bridge, F. J. Mortimer, C. B. Howdill, A. J. Newton and Mrs. Newton, George E. Brown, Miss Connell, Ernest Marriage, G. W. Norton and Mrs. and Miss Norton, P. R. Salmon, R. F. Carnegie, E. W. Houghton, Dr. E. König, Jules Fuerst, J. H. Baldock, Lady Ebury, J. S. Teape, G. Lindsay, Johnson, M.D., W. Rawlings, Thomas K. Grant, C. E. Kenneth Mees, Edmund A. Robins, C. H. Hewitt, J. W. Marchant, James A. Sinclair, Thomas Bedding, W. H. Harrison, Leslie Selby, C. G. Zander, H. Lenier, W. F. Butcher, H. Armytage Sanders, A. Brooker, P. Bale Rider, R. R. Beard, Miss K. Smith, Rev. F. C. Lambert, A. Haddon, R. Thiele, J. Hay Taylor, Miss Isabel Taylor, W. H. Rogers, W. J. Croall, J. W. Eadie, A. Horsley Hinton, J. Grubb, J. H. Agar Baugh, Cavendish Morton, Otto Fulton, J. Brown, Harold Hood, S. G. Kimber, S. J. Beckett, M. Arbuthnot, H. Creighton Beckett, C. H. Oakden, A. W. Goodman, F. L. Sargent, W. H. Wilshire, G. C. Whitfield, R. C. Murray, P. E. Marshall, Dr. Sutherland, Joseph Chamberlain, Dr. A. Richmond, W. H. Prestwich, Dr. A. R. F. Evershed, J. O. Grant, W. R. Stretton, W. Calder Marshall, H. C. Rapson, S. A. Pitcher, and J. H. Avery.

The exhibition was opened to the public yesterday (Thursday, September 21), and will remain open until October 28.

There can be no doubt that this year's show is a noteworthy one for many reasons. First; the abolition of the competitive element has, to a certain extent, altered the character of the exhibits in the Pictorial Section, inasmuch as the selection has been conducted on lines that have made the standard of work much higher in average quality. Secondly; the number of accepted exhibits being less than in any previous exhibition, more scope for effective arrangement has been possible with the hanging. Thirdly; the profession and the trade are represented on a more extensive scale than has been the case for many years; and, fourthly, the groups in which the Pictorial Section has been arranged have been panelled off by indescribable comet-like bunches of cream-coloured drapery that claim attention before anything else on the walls, and will probably live in the memory of visitors long after the last impression of the pictures has faded and been forgotten.

Apart from this, however, the scheme of hanging in the Pictorial Section has been carried out excellently, and every picture is seen to advantage.

The arrangement in panels is an improvement on the hanging of some previous exhibitions of the R.P.S., and no fault can be found with the disposition of the pictures. It will be noticed that the "tail," which seemed to inevitably arise when the first three unbroken walls of the gallery had absorbed all the best and biggest work, is conspicuous by its absence this year, and the variety and character of the pictures are noticeable from first to last.

Various shades of brown seem to be the prevailing tone of the majority of the pictures, the rest being mostly blacks and greys. With the exception of a couple of red gum prints, and one in bright green, no decisive note of colour is visible on the walls.

The frames are mostly dark, and there is a great tendency observ-

able to desert heavy solid frames for thin black or brown beads and wide mounts, either white or of a colour harmonising with the tone of the print. The effect in either case is much lighter, and the appearance of the prints is considerably enhanced, especially where two or more tints are used as subsidiary mounts.

It is difficult, now that technical data is not supplied in the catalogue, to say with any certainty what measure of popularity any one printing process enjoys among the photographs on the walls, but it appears that toned bromides and carbons run each other very close as first favourites. Gum prints do not seem to be very numerous. Platinotypes are fairly so, and P.O.P. is almost entirely absent. Much work, however, is on view that has been previously exhibited in the provinces, and many of the prints appear as quite old friends.

The general trend of the exhibition is towards landscape work. Portraiture and architecture are not strongly represented, although some excellent examples of both are shown. Among the portraits, William Crooke shows a striking portrait in the Pictorial Section, in addition to a very fine collective exhibit in the Professional Section. It is a standing figure study, "Jacques Thibaud, Violinist" (41), and is in the strong yet reticent style Mr. Crooke has made his own. A plain dark background and the figure half in shadow, with the lighting so arranged as to concentrate on the features. The effect is satisfying by its very simplicity and directness, and as an example of good studio technique this would be hard to beat. F. Hollier's "Holman Hunt" (1) is less vigorous than most of this worker's productions, but nevertheless is a good specimen of clean "big" portraiture. His "Camille Pissaro" (165) is likewise convincing, but the tones appear to be wrong, and the picture is lacking in contrast. The texture of the sitter's beard is lost, and the colour is somewhat dirty. "The Fur Cloak" (174), by Fredk. T. Hollier, is also rather dirty in tone, but as a portrait it has a fine painter-like touch that calls for commendation. "Portrait of an Indian Civil Servant" (17) is the title of a large head study by Dr. Chas. F. Grindrod. This is a good example of a somewhat heavy style of portraiture. It would be improved with a little more detail on the shadow side of the face, which is now entirely lost in the background. The insistence of the bolting cloth texture introduced into this print is not so displeasing as it would have been in a portrait with less breadth of treatment.

Two portraits by John Smith are notable as portraying two notabilities in the photographic world, "C. F. Inston, Esq., F.R.P.S." (26) and "Dr. C. Thurston Holland, F.R.P.S." (32). Both prints are vigorous little platinotypes; but surely Mr. Inston is not such a fierce, dour individual as he is here represented?

R. Dührkoop's three portrait studies are specimens of sound professional work, but one of them, "Studienkopf" (55) is somewhat spoilt by the scratchy handwork on the background. Dan Dunlop's "Portrait Study" (34) depends more on a fortuitous model for its success than any special merit in the production of the photograph. Nevertheless it is a good character study, and is well placed in relation to the space occupied by the sitter. J. C. Strauss exhibits two specimens of his work, of which "Mrs. Brooks" (58) is the better. The other, "Miss Ringen" (52), is not very convincing, either as a portrait or a figure study, but as a composition is pleasing. Mrs. G. A. Barton, needless to say, again displays her talents as a portrait photographer, and continues, in three of her contributions, to rely upon familiar models and formulæ for lighting, pose, etc. "The Mother's Kiss" (33) is, however, rather less hackneyed than usual, and contains some beautiful lines and tones. "A Churchwarden" (169) is very strong, and is one of the best character studies Mrs. Barton has yet given us. "A Parting Glance" (74) is a very typical "Barton," but not nearly so good as many previous photographs

of this same little girl. Pirie Macdonald's "Portrait Study" (135) is disappointing, and cannot, we imagine, be regarded as a specimen of the normal studio work turned out by this celebrated photographer. It is presumably a gum print, but is very dirty in tone and texture, and uncertain in shade and line.

"A. C. C. Jahn, Esq." (149), by D. Murray, is a good portrait, but rather too low in tone, and not high enough in the frame. The sitting figure is thus rendered rather squat and awkward. Pierre Dubreuil's exhibits are always interesting, and the examples he shows here are no exception. "The Fish Bowl" (25) is a variation of a similar subject treated by this worker several years ago. "Portrait of Mr. Debaene" (161) embodies an extraordinary concentration of light behind the sitter's head. This would be more effective if the handwork by which this effect was obtained were a trifle less obvious. The same remark applies to "Portrait of Mr. Giffard" (220), which is practically a silhouette. "Miss S. D." (182), on the contrary, is dainty in the extreme, and resembles a delicate little pencil sketch. "Whitworth Wallis, Esq.," by Miss Marian Silverston is a strongly lit portrait, and is evidently "a good likeness." One feels that the character of the man is portrayed very clearly here. H. H. Pierce's fine portrait study, "The Painter" (212), is one of the best of its kind in the exhibition, but is unfortunately rather marred by the white mount, which tends to kill the heavy tones of the print. "The Rt. Revd. John Dowden" (246), by John Moffat, has the charm of spontaneity, and is also a very pleasing composition.

The foregoing practically exhausts the portraiture in the Pictorial Section. The landscapes, with one or two exceptions, are not large in size this year, but make up in quality what they lack in quantity. J. C. S. Mummery's landscape work in gum is good, as affording examples not only of the application of the process, but also, as usual, very perfect specimens of composition. "The Mimram" (85) is perhaps the least pleasing. It is somewhat hard, and the sky appears rather blank. "January" (95) is very fine, and will probably be considered the best landscape in the show. It depicts a roadway in winter, with bare trees and snowy cart-ruts. The distance is beautifully rendered, and the whole tone of the picture is admirable. "Portsmouth Harbour" (4), by Bertram C. Wickison, is a fine composition, and a good idea of space is conveyed by the sails and reflections of some fishing boats in the near foreground, contrasting with battleships and docks in the distance. The effect of light upon the water is well rendered. J. C. Warburg's "Surf" (56) is a good arrangement of lines. A beach-wave running back over the sands and gathering volume for the return. A high sky-line and suggestion of "the front" assists the composition of the picture, and helps to accentuate the delicate tones of the surf and sand. W. T. Greatbach's "Evening—Caen" (122) conveys a wonderful rendering of limpidity in the water of the old harbour depicted. The tone and general effect of this picture is restful, and carries out the title admirably. Arthur Marshall's "Shade" (45) is another example of this clever worker's versatility and ability to see a composition in the most simple and ordinary materials. A courtyard paved with broken, uneven stones and an effect of light and shade, that is all, but a most delightful study in tones and lines is the result. Percy Lewis's "Fish Hawkens—Venice" (217) is not so successful as some of his Venetian street scenes. The pose of the principal figure is awkward, and although the technique is perfect, the somewhat unsuitable frame detracts from its value. Three very heavy gum prints by M. Arbuthnot will attract attention by their murkiness. "Eventide" (101) and "Before the Storm" (111) are fairly plain, and if not quite so dark and dirty, would be very strong indeed. "The Bridge" (141) is altogether too submerged in gloom for anything beyond the outlines of the subject to be deciphered. "Water Buttercups" (206), by Ernest Marriage, is a beautiful little study, very delicate in tone and decorative in treat-

B. Gay Wilkinson's "Early Spring" (109) is a little gem. As a landscape study it is the most perfect of its type in the collection. "A Spring Tide and a Flowing Sea" (92), by F. J. Mortimer, is one of the best of this worker's exhibits. It depicts a foaming breaking over rocks, and the composition is considerably assisted

by a fine bank of clouds leading down to the principal point of the breaking waves.

Further notes on the Pictorial Section will be given in our next issue. The Technical, Professional, and Trade Sections will also be dealt with later.

THE PHOTOGRAPHIC SALON.

SECOND NOTICE.

Our second visit to 5a, Pall Mall East, strengthens our belief that the Photographic Salon this year is far in advance of any previous show mounted by the members of the "Linked Ring." The "photogenic" element, which has on more than one occasion been somewhat conspicuous by its absence, much to the amazement of the sophisticated visitor, is very strongly in evidence in the present edition. Our professional friends, too, will find much that is interesting and striking in the way of portraiture.

As we mentioned in our preliminary notice last week, there is a proportion of the pictures on view which can only claim attention as examples of handwork, but in most instances these are to be found among the American and Continental exhibits.

Prominent among the English portrait work are the examples by Craig Annan, Frederick H. Evans, and Frederick Hollyer. The portrait of Miss Jessie M. King by the first-named we referred to last week, and a close inspection of this delightful work will repay any photographer interested in the correct portrayal of textures. It is a three-quarter-length figure study, and not only the pose, but the qualities of the photography, both technically and pictorially, are as good as one can wish for. The lighting is simple and effective, and the texture of the background gives a grainy effect the whole that is very pleasing. "E. A. Hornel, Esq.," is another excellent portrait, as also is "J. Cleland, Esq., M.D., F.R.S." Mr. Annan's two other exhibits, "Portrait of Mrs. C." and "R. B. Ingham-Graham, Esq.," should likewise be studied carefully, the latter in particular showing how the Velasquez-like type of face has been turned to the greatest advantage.

Frederick H. Evans's contributions include only two architectural studies, and although we may be gainers by Mr. Evans's portrait work, we confess to being disappointed at not seeing more of his specimens of architectural photography. "A Watchful Prior—" and "Afternoon Sun in Wells Cathedral" are, however, very representative. Of his portraits, "George Bernard Shaw" is the best. "A. Horsley Hinton" is the least pleasing. "Churcher Smileth" is straightforward, and those who are familiar with that versatile humorist, Mr. Walter Churcher, will appreciate this picture to the full. Frederick Hollyer and Frederick T. Hollyer, his son, are responsible for four portrait studies. The finest of these is of Frederick H. Evans, by Hollyer, sen., and is a striking likeness of the secretary of the Linked Ring. The poise of the figure, the position it occupies in the frame and the frame itself are all in keeping and can be regarded as one of the best things Mr. Hollyer has done. "S. Solomon" we do not care about. Both pose and expression are strained, and as a portrait study does not appear to be good, although as a composition it may be a success.

Frederick T. Hollyer's two portraits are curiously tinted. Whether this is due to three-colour work or other means is not quite clear, but the results are not pleasing, and the tinting is weak and unconvincing.

J. Cruwys-Richards has one or two portrait studies that are interesting examples of composition and lighting. The best of these is "Portrait of Mrs. C. Richards"—a strong profile study. All Mr. Richards's work is, we presume, in the gum bichromate process.

Of the American portrait work, that of A. L. Coburn is the most noteworthy, not altogether on account of its quality so much as its

quantity. Five specimens of this photographer's efforts are placed in a row and other examples of his work, not portraiture, are hung near by. The placing of five large portraits thus adjacent to each other, and all alike in character and mounting, is a very good test of the value of this type of photography would have in the average professional's show case. We do not think that in England they would fetch, in the ordinary way of business, five guineas each, which is the price Mr. Coburn has fixed for them. We cannot, however, deny that these portraits are very fine in many ways. The subjects are treated broadly and the photography is sound. The characteristics of each sitter, too, appear to have been caught effectively, which redounds to the credit of Mr. Coburn. The portraits of Solomon J. Solomon, R.A., and Mark Twain are the best of the series.

Portraits by Edward J. Steichen, Mrs. Gertrude Käsebier, and J. T. Keiley are of the most advanced type of impressionism, but are unquestionably strong and pictorial, as also is the portrait study by Miss Landon Rives—"Mrs. H." We miss, however, the clean, strong work one is accustomed to associate with the leading portrait photographers of America, and expect, if it was submitted at all, it received the same treatment at the hands of the American Links that the work of many leading British professionals would receive from their English confrères. The French portrait work is somewhat emotional, but is frequently strong. Most of it, needless to say, is in gum, and the work of Demachy and Puyo is easily identified. Two contributions by R. Le Bégue are exhibited, we presume, as evidences of misplaced energy and ability. They represent pages from an artist's sketch book. One contains three unfinished nudes and the other three heads. When it is considered the amount of trouble, labour, and material that has been expended in producing what, at the best, resembles but an unfinished note or two jotted down for reference and economy in a sketch-book, any beauty that these productions may possess is entirely lost sight of in the absurdity of the method of producing them.

We are glad to note several examples of the work of R. Dührkoop on the walls. This photographer is in the front rank in Germany, and the specimens here shown are very fine indeed. "Gruppe," a delightful composition of mother and child, is worthy of very close study. The pose of both figures and the spontaneity of the little one's expression are perfect. "Bildnis des Dichters Gustav Freussen" is also a fine study, and can be regarded as a good model for the portrait photographer to copy.

Dr. F. V. Spitzer has also a couple of fine portraits. These are large heads, and are quite strong and vigorous in their lights and shades. Among the other foreign work, red gum prints and portraits in four or more colours are very noticeable. To the ardent "gummist" the productions of G. Grimpel, Mlle. C. Laguarde, A. Hachette, P. Dubreuil, Th. Mahéo, and A. Hachette will undoubtedly appeal, as also will some other examples of Steichen's work. The Americans also have several specimens of coloured gums, but their effects are generally more weird than the French productions. Alfred Stieglitz, however, shows one or two excellent photographs, of which "Going to the Post" is the most striking. Clarence White, C. Yarnall Abbott, William B. Post, Harry C. Rubincam, and R. Eickemeyer, jun., are among those representing American pictorial photography. The pictures by Heinrich Kühn are noteworthy, if only on account of

their undoubted strength and breadth of treatment. "Tuder Düne" is a fine composition, and its fuzziness is not altogether unpleasant if the idea that it is a photographic production can be dispelled.

The landscapes at this year's Salon are—on the whole—very strong and run the portraits close in point of interest.

Charles Job, Alexander Keighley, and A. Horsley Hinton have each got several representative pictures on view, but in each case these exhibitors have not reached the standard set by some of their previous work. Charles Job, for instance, has nothing here to touch his "Evening Calm," "Sheep and Lambs," or "On the Arun." The best of his series is "Low Water—Evening," but this does not appear to have the finish of the pictures mentioned. The sky is too theatrical and the general effect is hard. Alexander Keighley's four pictures are, as usual, strikingly complete in the matter of composition, but they do not show to advantage in the strong light of the present gallery. There appears to be no depth in the shadows, and the appearance of each print is flat and lacking in contrast. This is particularly observable in "The Al-fresco Bath," which has for its subject an Italian wayside fountain, in which a small boy is being bathed by his mother. Here the beauty of the composition and the whole appearance of the print would be enhanced if the stone arch above the fountain was several tones lighter in colour.

The landscapes by A. Horsley Hinton are large, as usual, but do not seem up to his usual standard. "Hill Top" is, perhaps, the most striking, and we fancy we have seen this subject before. If we mistake not this picture, or another remarkably like it, was hung in the same position at the last exhibition held by the Royal Photographic Society in these rooms. The keynote of this composition is simplicity, and for that reason is more effective to us than the rather over-elaborated "In Airedale." "Rylstone" is, however, more in Mr. Hinton's usual style, but none of his works this year are quite so satisfying as many of his previous efforts. Charles Moss has only one print at this exhibition. It is, of course, a large and somewhat heavy gum print, and shows, as usual, a great amount of handwork on the print. It is called "Chaldron Bay." F. J. Mortimer's "Peace," although a seascape, is somewhat out of his usual groove, as it includes a sailing vessel. It is a very effective study of sunlight, calm sea, and mist. His two other seascapes, "Abandon" and "Strife," are as good as anything he has yet done. The former is a horizontal composition with a huge roller sweeping right across the picture and dashing on the rocks to the right, and the latter reminds us of "The Reef" of last year, but is stronger in light and shade and has more action.

Will Cadby shows several of the dainty little child studies we have been led to expect from him, and Mrs. Cadby's sole contribution, an extraordinary cat study, is unworthy of the producer of the beautiful photographs of flowers and grasses we have been accustomed to from her. George Davison has three typical landscapes this year, of which we like "Molesley Lock" most. "A Wet Sun" is also very pictorial. Ward Muir again gives us three examples of his powers to make one small piece of printing paper serve for three exhibition pictures. They do not altogether demonstrate that quality is better than quantity, but "In Roquebrune" calls for most attention, apart from the fact that it is the largest of the three. Reginald Craigie has only one picture this year, "Bernadette," a straightforward photograph of a little girl, which is pleasing on account of its simplicity.

Mrs. G. A. Barton's work is very unmistakable, and, with one exception, her child models are again in evidence. The exception is a fine study of an old man, "For the night cometh when no man can work." Apart from its rather unconventional shape, this is one of the best examples of figure work we have seen from Mrs. Barton. E. T. Holding has several strong figure subjects, of which "Music" is a very pleasing arrangement of two models. The lighting in this

composition is rather hard, and suggests flashlight. Arthur Marsh has three very good pictures: "A Dusty Day," being not only remarkably fine composition, apparently a snapshot, but giving a splendid idea of action and perspective. "The Frontier" is an uncommon arrangement of lines, and its very unconventional makes it attractive. It represents an unbroken line of tall, gaunt trees by a river's bank. David Blount's pictures are, as usual, rather low in tone and scratchy in execution. "The Columbine" is perhaps the best. Archibald Cochrane has four interesting pictures, of which "The Barrel" and "Mont St. Michel" are most striking. The latter has a remarkably fine cloud effect. Eustace Calland's pictures are, as usual, clever, but, with the exception of "The Village Inn," do not quite reach the standard of his "Hanover Square" of last year. Dr. E. G. Boon shows a couple of fine little genre studies and a landscape. Walter Benington's work is disappointing, "A Rosebud" being about the best of his series. A fine study of light and shadow is shown by A. J. Anderson in "Curbed," which depicts a locomotive in a smother of smoke and steam. A. H. Blake and J. H. Anders both have several good prints, and Edward Seymour has one of the technically perfect fruit studies. We miss, however, the beautiful fruit and flower studies that Mr. J. M. Whitehead used to treat us to. We have instead a couple of quiet but very perfect little landscapes. J. C. Warburg's two efforts are seascapes. They are quite meek and demure, and one of them, "Backwash," has a break in the wave that appears to be nicely combed and curled. The secret of J. M. C. Grove's "Winter Gloom" is locked up in the author's bosom, and we have our doubts whether G. E. H. Rawlins's "Woodland Pool" is hung the right way up. Miss Constance Ellis has a dainty little picture, "Casablanca, Morocco," which, although good, is not so welcome as this clever lady photographer's figure studies. Mr. Warburg, Miss Marian Silverton, Cavendish Morton, W. Thorne, Fred. Judge, Charles F. Grindrod, W. A. Stewart, A. W. Hill, Chas. H. L. Emanuel, and J. Page Croft have also examples of their work on view, but space does not permit of more than a reference to them. The exhibition remains open until October 21, from 10 a.m. to 6 p.m. on Monday and Wednesday and Saturday evenings from 7 p.m. to 9.30 p.m. As in former years the general committee invite their visitors between 4.30 and 5.30 to a cup of tea.

R.P.S. EXHIBITION.—A good programme of lantern lectures has been arranged to be given in the North Room at the New Gallery on Monday, Thursday, and Saturday evenings at eight o'clock. Tomorrow (September 23), Mr. A. Brooker will give a lecture on "Winchelsea and Rye"; on Monday next (September 25), Mr. S. Beckett will show a series of "Alpine Pictures," and on the following Thursday "A Journey to Fanatical Fez" will be the subject of a lecture by Mr. J. H. Avery—by request.

INTERNATIONAL SOLAR RESEARCH.—A conference of the International Union for Co-operation in Solar Research will be held on the 27th inst. at New College, Oxford, by invitation of the Warden and Fellows of the College. The subjects of discussion will include the fixing of standards of wave length in spectroscopic research, co-operation in the measurement of the intensity of solar radiation, co-operation in recording solar phenomena by means of photographs of the sun, disc, spectro-heliograph records and observations at the limb of the sun.

ST. MATTHEW'S (BOOTLE) CAMERA CLUB announce their second annual exhibition will be held in St. Matthew's Parochial Hall, Thornton Road, Bootle, on November 16. There are three open classes. H. Tempest, 78, Thornton Road, Bootle, Liverpool, is the hon. sec.

Photo-Mechanical Notes.

Film Lantern-slides by Lithography.

Attention is called in the "Zeitschrift für Reproduktions-technik" to the advantages of a light, flexible lantern-slide or one on glass in point of price and handling in the trade, and to the drawbacks of the transfer process by which the slides are usually made. An excellent substitute for the transfer process, and one productive of a slide which can be cheaply produced and cheaply transmitted through the post, is based on the use of hardened gelatine, on which the pictures are printed direct from stone without difficulty, and the results of which are satisfactory, provided a proper selection of colours is made. For stone-printing on gelatine, the gelatine sheets should be uniform, and as thin as possible without risk of breakage. Uniform transparency is naturally a *sine qua non*, and suitable gelatines can be obtained from a number of manufacturers. The sheets are dusted over on the sides to be printed with a soft brush, and then, immediately before laying on, with a soft brush. The machine must be worked very slowly; the inking must be good, and liberally applied, and what is most important, the ink must be very slightly dampened. In regard to the inks, it must be borne in mind that all body colours will appear absolutely black in the projected picture, and are only to be used for outlines, for which purpose pigments of intense covering power should be chosen. For all other purposes, the transparent, "lasur," colours should be exclusively employed. Mineral colours, such as chrome yellow, etc., cannot be used, and the "Krafft" reds have also far too great covering power. In exposing colours, the picture must be judged by transmitted, reflected, light, and a colour must be chosen flatter—i.e., more faded—than for an impression on paper. The ink is mixed with sufficient fixative for the quickest drying practicable, as the prints have all to be laid out to dry by free exposure to the air, the gelatine, unlike paper, absorbing none of the ink. After an interval for drying of from six to eight hours, the second printing can be done, and so the process is continued. It is advisable to apply the colours in order the reverse of that for paper—viz., blue, red, and, lastly, yellow—the key plate being printed first. The printed transparencies are completed by cutting up the sheets and binding up each picture with a somewhat outer piece of gelatine.

Increasing the Sensitiveness of Bichromated Fish-glue and Albumen.

In the current issue of "Photographische Korrespondenz" Herr Tschörner, of the Vienna School of Graphic Arts, describes the results of the process for imparting greater sensitiveness to fish-glue and albumen printing solutions by addition of dyes. The formulæ examined by Herr Tschörner are those of MM. Calmels and Clerc, published some months ago, and reported in "Photo-Mechanical Notes" for June 16, 1905. Two plates were printed side by side, one dyed and the other undyed. The dye used was the purest erythrosine (tetraiodo fluorescein), of Grote, Basle, and it was added to the sensitiser in the proportions of .05, .1, .15, and .2 per cent. but in no case could any shortening of the necessary time of exposure be noticed. On exposing both plates for half the time required for the undyed plate, both floated off on washing in water, the dyed as well as the undyed. Further than this, when the undyed film was correctly exposed, and a film containing .05 and .1 per cent. of dye exposed for the same period, the strongly stained film was insufficiently printed: the dye had lowered, instead of raised, its sensitiveness. Similar results were obtainable with albumen, and convinced Herr Tschörner that the dye in his experiments acted strongly as a screen, and thus lowered the sensitiveness of the plates.

Patent News.

Process patents—applications and specifications—are treated in *Photo-Mechanical Notes*.

The following applications for patents were made between September 4 and September 9:—

PRINTING MACHINES.—No. 17,896. Improvements in photographic printing machines. George Hana, 22, Bedford Street, Strand, London.

PRINTING FRAME.—No. 17,908. An improved photographic printing frame. John Batty, 124, Willis Street, Lozells, Birmingham.

No. 18,195. An improved photographic printing frame. William Gale, 4, Smarts Lane, Loughton, Essex.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

DAYLIGHT DEVELOPMENT.—No. 19,164, 1904. The claim is for a camera into which is built a vertical tank to which the plate is transferred from the dark slide, and in which it is developed and fixed. The apparatus resembles others in which this plan has been advocated. Hans and Hugo Tirmann, Pielach, near Melk, Austria.

STEREOSCOPES.—No. 21,637, 1904. The claim is for a portable stereoscope, consisting of two portions hinged together, the one of which carries the lens, and the other the view carrier, as shown in the

Fig. 1.—The film package.

Fig. 2.—The exposing chamber or adapter.

figure. The case may conveniently be formed as a book cover having a hinged back, 2, whereby it may be opened out flat. On one side (or both sides) of the hinged back, 2, the sides, 3, of the case or cover may be turned up at right angles as shown to represent the side edges of a book when closed, and to form a support for the opposite half of the case, 1. On the front edge, 4, may be fitted, by a joint or hinge, 5, a shaped piece to form a lens carrier, 6, with folded-over edges, 7, at top and bottom to permit of the lens-holders or frames, 8, sliding therein, whereby they may be laterally adjusted to the eyes of the user. In or about the centre of this same half, and extending inwardly at a right angle to the lens carrier, may be fitted by a joint or hinge, 9, a piece forming a screen, 10, with folded-over edges, 11, at

top and bottom, which form guides within which a slide, 12, is movable to form an extension of the screen. On the upper edge of the screen, and adjacent to the lens carrier, is formed a lip or bent piece, 15, adapted to fit into a catch piece, 16, attached to or formed on the upper and inner folded edge of the lens carrier, so that the screen and lens carrier are held firm when in an upright or open position. On the opposite half of the cover are grooves for a sliding view carrier, 18, the side edges, 19, of which are bent over to retain the stereoscope views in the carrier 18, the latter being preferably made as shown as a double

frame, hinged at 20 to a flat slide, 21, whereby it may be folded flat when out of use. Sidney Herbert Bath, 97, Grove Lane, Camberwell, London, S.E., and the Rotary Photographic Co., Ltd., 12, New Union Street, Moorfields, London, E.C.

NON-INFLAMMABLE CELLULOID.—No. 22,381. The admixture of boric acid with nitro-cellulose and camphor is claimed as a method of producing a non-flammable celluloid. W. C. Parkin and Alfred Williams, Damstead Works, Bronfield, Sheffield.

ROLL HOLDER.—No. 190, 1905.—The invention relates to a system of daylight-loading roll film, in which the protecting wrapping of black paper is dispensed with. The packet of sensitive film to be exposed in a chamber or adapter which can be adapted to any camera, consists of a shallow box of wood, or other suitable material, of sufficient width to allow the film in use to run freely, but without too much play. The length and width of the box are sufficient to allow of the usual exposure aperture, and the depth to accommodate the roll of sensitive film. Immediately behind the exposure aperture in the front of the box is fixed an opaque partition, which is fitted in a light-tight manner to the sides. This partition may be of thin sheet metal, cardboard, etc., and is of such a length that it extends nearly the whole length of the interior of box, the ends being rounded to allow of the smooth running of the film in the process of changing, and a narrow slit being left at each end through which the film passes. The slits may be lined with plush or velvet for the purpose of making the package perfectly light-tight. At a convenient position behind the partition is provided a small pivoted roller, *e*, extending from side to side of box, and is intended to receive the exposed film. The ends of roller are pivoted into the sides of box, and one end projecting through is provided with a slot or key-way to engage with the lower part of winding handle contained in the adapter. The charge of film is provided with a tab of paper, which is threaded through the aforesaid slits on to the roller, which may be furnished with a threading slit in the manner of ordinary film spools. The tab is of sufficient

length to extend completely round the partition, across the exposure aperture, and thence to the receiving roller, around which it should take several turns to ensure a certain grip. The roll of film is simply a hollow roll, of the necessary length and width, which is kept in place by means of a wire or rod extending from side to side of box through the centre of roll, or the wire or rod can be dispensed with and the roll allowed to run from one end to the other, it is fed off. After the charge of film is threaded as described, the cover of the box is fitted on and the joint covered with a pasted strip so as to form a light-proof package, and this package will form an article of commerce, it being of so little value that it can be discarded after once using. The adapter is made in the following manner:—To one side of a rectangular frame—of suitable dimensions to receive the film package in use—is hinged a back cover. On the opposite side a flat frame is fixed, containing an exposure aperture similar to the frame of a dark slide, and, like the slide, is furnished with a sliding opaque shutter for the purpose of exposing the sensitive film when the adapter is removed from camera. During the process of focussing or for other purposes. At one end, and on one side opposite to the end of the aforementioned shutter, is provided a winding handle, which is extended downwards to form a key which engages in the recessed end of the roller, and allows of the film being wound up as many exposures are made. The key is adjusted to enter the key-way when placing the package in the adapter. In connection with the winding handle, a device can be provided for the purpose of recording the number of exposures. The claim is confined to the construction of a roll holder in such a manner as to make it commercially practicable to adapt it to the system of daylight loading (other than the well-known plan of daylight loading of spools or cartridges in which the sensitive film is wrapped round a core of wood and is protected with a strip of black backing paper considerably longer than the film itself) and to detail a mechanism for correctly spacing and automatically locking the winding handle when sufficient film is wound off for the necessary exposures. Although a plain roll of films appears to be most suitable to the new system described herein, it would be quite possible to use it in connection with paper-backed film. The package in this case would necessarily be more bulky than a given length of film. William Albert Edwards, 51, Vant Road, Tooting, London, S.W.

A MODIFIED GUM PROCESS.—No. 11,077, 1905. The invention relates to pigment bichromate processes, and lays stress on the method of manufacture, in which the paper is first coated with a solution of colour and then with a layer of bichromated albumen, or albumen to be bichromated. It is claimed for this method that it has the advantage that the layer of colour will not become dissolved and intimately mixed with the layer which is used as a carrier for the sensitising medium when it is quickly applied. Beautiful brilliant shadows with dull lights and properly graduated half-tones will thereby be obtained. Another important advantage is that the time of exposure indicated by the photometer need not be altered in accordance with the different colour of the pigment paper, as the light always passes through a uniform uncoloured upper sensitive layer, whereas, if the layer of colour is at the top, as in ordinary carbon or pigment paper, it acts as a light-filter or screen. Properly sized paper is coated with a soluble layer of colouring matter in a uniform manner and dried. Then a solution of bichromated albumen (say 10 parts by weight of albumen, dissolved in 100 parts by weight of bichromate of potash 1:10) is applied over the layer of colour, or, instead of this solution, a colloid substance, such, for instance, bichromated dextrine (1:2), may be used, and the whole

is left to dry again. The paper is now ready for use, and the printing is accomplished with the aid of a photometer, whereupon it is soaked in cold water and developed, say, with a brush. Owing to the action of light, the colloid surface, and the colour under it, will become more or less insoluble, according to the exposure and owing to the thin layer of colour and colloid, the finest half-tones are produced. Karl Pflanz, 30, Graben, Linz a/D.

News and Notes.

From the Northampton Institute, Clerkenwell, E.C., we have received the programme of lectures and laboratory courses contained in almost every branch of technology. The official department, under the direction of Mr. S. D. Chalmers, B.A., M.A., represents the branch of instruction for which students of photography are most likely to visit the Institute, inasmuch as photographic optics receives a notable place in the curriculum. The following extracts from the syllabus of Mr. Chalmers' lectures on optical instruments and "Design of Optical Instruments" will explain the aims of the teaching executive:—Photographic apparatus (eight lectures, October 31, 1905–December 19, 1905).—Construction of cameras. Details of adjustments; simple landscape lenses; importance of stop as regards illumination and correction of defects. Nature of defects, their influence on image; symmetrical objectives, modern forms. Effect of light on photographic plates—orthochromatic plates and screens; requirements of colour photography, the testing of photographic lenses. Stops, shutters, construction, and testing. Telephotography. Stereoscopic apparatus. Photographic Lenses.—Design of simple achromatic and rationally compensated landscape lenses, use and position of stop; distortion, double objectives principle of spherical correction of aberrance and exit pupils; curvature of field condition for flattening, achromats; anastigmats, Rudolph's principle, illustrations of lens lenses; convertible anastigmats and their design.

The sixth annual exhibition of the Burnley Camera Club will be held in the Assembly Hall, Mechanics' Institute, Burnley, from November 16 to 18. There are four open classes, and four for local photographers. Entries close November 8, and exhibits must be delivered at the Mechanics' Institute by November 14. Mr. F. Under is the hon. sec., and applications for entry forms must be made to him at above address.

A PHOTOGRAPHIC exhibition will be held on February 20 and 21, 1906, at the Royal Albert Institute, Windsor, under the patronage of their Majesties the King and Queen. There are twelve classes, of which four are open. J. W. Gooch, Royal Albert Institute, Windsor, is the hon. sec.

MANY photographers, both amateur and professional, will hear with regret of the death of Mr. Samuel Blatchford Webber, which took place at his residence, Bromley, Kent, on Sunday last, the 18th inst., at the advanced age of eighty-six. Mr. Webber was a skilled goldsmith, and as recently as the Newcastle meeting of the Photographic Convention gave a practical demonstration as to what could be done with residues, by making a gold ring out of them and presenting it to the president. He was an excellent and painstaking amateur photographer, his labours dating back for a considerable period. He was vice-president of the Bromley Camera Club, and for many years was one of the trustees of the Photographic Convention, a position which he resigned only a few months since owing to ill health. The deceased was a very interesting and pleasing personality, and a courteous and kindly gentleman.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
22	Cardiff Photographic Society	"Selection of Subject and Exposure." Mr. A. E. Harris.
23	Glasgow Southern Photo. Assn.	Castle Semple. Mr. R. Lindsay.
23	R.P.S. Exhibition	"Winchelsea and Bye." Mr. A. Brooker.
23	Luton Camera Club	"Ozotype" (Gum). Mr. Thomas Manley.
25	R.P.S. Exhibition	"Alpine Pictures." Mr. S. J. Beckett.
25	Southampton Camera Club	F.R.P.S.
26	Manchester Amat. Photo. Soc.	Illustrated Lecture. "A Founder of Empire." Mr. F. G. Ryder.
26	Southampton Camera Club	"Lantern Slide Making." Mr. F. W. Parrott.
28	London and Prov. Photo. Assn.	"Art by Photography." Rev. H. W. Dick.
28	Handsworth Photographic Soc.	"Portrait Photography." Mr. C. H. Hewitt.
28	R.P.S. Exhibition	Demonstration—Lantern Slide making, by contact. Mr. R. J. Funnell.
28	R.P.S. Exhibition	"A Journey to Fanatical Fes." Mr. John H. Avery.

BRISTOL PHOTOGRAPHIC CLUB. This club has decided to remove to more convenient premises. A good suite of rooms (including a dark-room) has been secured from the Committee of the Y.M.C.A., St. James's Square. The opening of the winter session will take place there on Tuesday evening, October 3, when Mr. Morris B. Fowler will give a practical demonstration and paper on "Exposure and Development."

ATTERCLIFFE PHOTOGRAPHIC SOCIETY.—A meeting of this society was held in the Friends' Meeting Room, Leeds Road, on Monday night, when Mr. A. Birtles gave a lecture on the photographing of clouds.

The opening meeting of the Blairgowrie Photographic Association for the winter session was held on Tuesday night last, when a paper on Turner's "Liber Studiorum" was read by Mr. H. D. Ross, vice-president.

The annual meeting of the Keighley Photographic Association was held last week. The report of the secretaries (Messrs. H. E. Haggas and W. H. Hainsworth) showed that the membership had decreased from eighty to seventy-six, and the treasurer (Mr. E. P. Heaton) announced that the balance of £18 13s. 7d. at the beginning of the session had been reduced to £3 0s. 5d. There were several sums still to come in. The following officers were appointed:—President, Mr. W. Robershaw; vice-presidents, Messrs. F. Mahony, C. H. Smith, J. G. Dickinson, W. H. Hainsworth, and T. Heaps; treasurer, Mr. H. E. Haggas; librarian, Mr. F. Gill; lanternist, Mr. A. Stell.

DEVONPORT CAMERA CLUB.—The annual meeting of this club was held on Tuesday last. The Committee reported that the progress of the club continued in every way to be satisfactory. The membership showed an increase, and the attendance had been exceedingly good at the twelve meetings. Mr. W. Treglohan was elected president, Messrs. A. J. Catford and J. F. Coombes were re-elected hon. secretaries, Mr. F. B. Langdon was re-elected hon. treasurer; Messrs. W. H. Mayne, R. Maw, J. T. Trend, and J. Cock were elected vice-presidents; and Messrs. J. Batten, G. D. Graver, E. A. Earl, and R. E. J. Lamb the committee. Rev. H. O. Fenton, and the president were appointed delegates to the Royal Photographic Society. Mr. W. H. Lamb, auditor, and Mr. S. J. Heal, lanternist, were re-elected.

PLYMOUTH PHOTOGRAPHIC SOCIETY.—At the annual meeting of this society, held on Friday last, the hon. secretary reported a most satisfactory year's work and increase of membership. Mr. J. T. Johnson was re-elected president, and Messrs. Blanchard and A. E. Coleman vice-presidents, Messrs. W. Clayden, C. H. Dymond, W.

Grist, H. S. Hill, A. B. Fellowes-Prynn, R. A. Shapcott, and F. A. Wiblin, committee; Mr. A. W. Hicks, hon. secretary; and Mr. J. T. Trend, hon. treasurer. Messrs. E. G. Turney and H. S. Hill were elected delegates to the R.P.S.

WARRINGTON PHOTOGRAPHIC SOCIETY.—The annual meeting of this society was held at the Old Academy on September 5. Mr. Smithson, the secretary, read the report for the past year, and recorded a very satisfactory year's work. The membership stood at about eighty. The committee, however, desired to point out that unless every member of the society was prepared to do his or her best to add to the number by introducing good working members, it would not be possible to provide such a profitable series of lectures, etc., as they desired. The following officers for the ensuing year were elected:—President, Mr. F. V. L. Mathias; vice-presidents, Alderman Bennett, Messrs. J. Fairhurst, James Harding, William Winstanley, F. G. Taylor, Peter Dalton, and Mrs. Mathias; committee, Messrs. D. S. Birrell, George Nicholls, K. F. Bishop, F. W. Purse, H. Smith, G. Smith, Mrs. A. C. Smithson, and J. Dolan; curator, Mr. F. J. Eardley; auditor, Mr. Peter Dalton; secretary, Mr. A. C. Smithson; treasurer, Mr. F. Garside; lanternist, J. V. Moore, assistant lanternist, W. S. Birrell.

WINTER PROGRAMMES.—We are pleased to note, by a batch of winter fixture-cards just to hand, that there is still a considerable amount of activity to be found among the British photographic societies. From the EDINBURGH PHOTOGRAPHIC SOCIETY's syllabus we learn that some lectures of considerable practical interest will be delivered by various members. On October 4 James Burns will give "a plain talk" on "Some Essentials to Picture Making"; Archibald Cochrane will lecture on "Pictorial Aim in Photography" on December 6; and T. Cuthbert Day demonstrates "Colour Photography in Theory and Practice for Amateurs" on January 3; and "Composition and Chiaro-oscuro" will be illustrated by W. Grant Stevenson, R.S.A., on April 4. Many other good lectures are also fixed. The GLASGOW EASTERN AMATEUR PHOTOGRAPHIC ASSOCIATION has, among other attractions, a demonstration on gum-bichromate on October 12 by Dr. Andrew Richmond, "Carbon Printing" by Dan Dunlop on Oct. 26, and "Artistic Mounting of Photographs" on October 19 by J. S. Melville, "Transparencies and Enlarged Negatives" by M. Crosbie on December 14, and "Reduction and Intensification" by David Horn on December 21. The MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY also has a promising fixture list, and the CARDIFF PHOTOGRAPHIC SOCIETY and the NORTHCOTE CAMERA CLUB show all the necessary evidences of vitality. The LUTON CAMERA CLUB promises its members *inter alia* a lecture on three-colour photography on November 6 by Murray Barford, and a practical evening on "Auto-Pastel" by Messrs. Staddon and Baker on November 13. "Visual v. Factorial Development" will be dealt with by Messrs. Warren and Cox on November 20, and Dr. F. Seymour Lloyd will give a practical demonstration of X-ray work on November 27. The HANDSWORTH PHOTOGRAPHIC SOCIETY, the DARLINGTON CAMERA CLUB, and the KINNING PARK CAMERA CLUB have interesting sessions before them; whilst from the AUCKLAND CAMERA CLUB and the SOUTH AUSTRALIAN PHOTOGRAPHIC SOCIETY come programmes that prove our cousins at the Antipodes are quite as active as the photographers of the Old Country.

RODLEY, FARSLEY, AND CALVERLEY DISTRICT PHOTOGRAPHIC SOCIETY.—The annual meeting was held on the 14th inst. Mr. W. Whittaker, of Rodley, was elected president. The treasurer, Mr. Albert Matthews; the Yorkshire Union delegate, Mr. Ashby; and the secretary, Mr. Crossley. The retiring president (Mr. Gaunt) offered a prize of one guinea, and the society one of half a guinea for the two best pictures by the members at the society's annual exhibition in February next.

New Materials.

Christmas Mounts. Published by Messrs. Marion and Co., Ltd. 22 and 23, Soho Square, London, W.

The slip-in or paste-down mount for the reception of a photograph, and the final purpose of Christmas souvenirs, has been such a fixture in the photographic stationery trade, that we anticipate the arrival of new styles for the season before the sun is hardly gone. Messrs. Marion and Co. are first in the field with a list of motto mounts, all of a festive character, which run to eight pages, and includes an immense number of designs of various sizes. Amongst these there is surely enough choice in colour, style, and price to suit the most fastidious. We see Messrs. Marion include mounts for photographs of postcard size, an innovation. Christmas mounts which is interesting in view of the fear sometimes expressed that the picture postcard would seriously compete with the Christmas card as a medium of greeting. A mount postcard is, therefore, opportune, and provides a means of proving how much better the postcard looks when neatly framed and enclosed.

CATALOGUES AND TRADE NOTICES.

A SERIES of monochromatic flash-candles has been introduced by Dr. G. Krebs, and is placed on the market by Messrs. A. E. Staley and Co., 19, Thavies Inn, London, E.C. The candles are prepared to give monochromatic lights to answer the purpose of blue, green, or red filters in the exposure of plates for three-colour photography. Other forms of monochromatic flashlight are also supplied, and attention is drawn to the advantages of the new introductions for monochromatic photography under various difficult circumstances. Messrs. Staley's circular gives the prices of the candles.

Correspondence.

* * * *We do not undertake responsibility for the opinions expressed by our correspondents.*

THE ACTION OF METOL AND ORTOL ON THE SKIN.

To the Editors.

Gentlemen, For many years I have suffered with my hands when using amidol and metol. The symptoms used to extend to my wrists which would be a complete mass of sores, and my hands and arms itched exceedingly. I have tried almost every kind of ointment without success, but I have at last found a successful remedy as follows:—Before developing I grease my hands well with lard, then wipe them so that the grease will not affect the print. After developing I wash my hands with very hot water—as hot as I can bear my hands. When the grease is removed, I make a solution of alum, 1 oz. a pint of water, place my hands in this, and allow them to remain for a few minutes. I then wipe them, without further washing them for at least an hour. Since doing this I have had no trouble with my hands, whereas previously they were almost raw. If others who have suffered from the effects of developing as I have will try this I do not think they will suffer again.—Yours truly, F. HUGHES
Leicester, September 13, 1905.

THREE-COLOUR PORTRAITURE.

To the Editors.

Gentlemen,—In your very interesting article on three-colour portraiture you say: "Comparing three-exposure with one-exposure cameras for three-colour work, the balance of practical advantage would seem to lie with the former, for the latter are costly, more difficult adjustment, and introduce extra filters." Practical advantage is, in your mind, that if your sitter moves during one exposure all three negatives have to be thrown away, because, if he moved in the sitting, say, for the red-sensitive, that is, the panchromatic, plate, you would have a negative to be printed in blue, in which you would give in proportion to the movement involuntary predominance to the yellow and the red printing plate. I should think this is a decided disadvantage of the three-exposure camera. Now, if you had a one-exposure camera, with one lens, then if your sitter moved slightly during exposure all negatives would show the same movement, and no predominance would be given to one colour. In fact, a slight movement would not mean a bad picture; ergo, there is a decided advantage for the one-exposure camera. In the three-exposure camera three filters are required, and I am sure that in the one-exposure camera this number will not be exceeded, and if you adopt Bennetto's system (not minding certain inherent defects), only one filter is required.

Now for the costliness of the one-exposure camera. How many are in use? Are there two persons that have one, and who are also able to show some prints, say cabinet size (not chromoscope positives) taken with a one-exposure camera? Does that look as being of commercial value to manufacturers? If you can warrant an order of 100 half-plate one-exposure cameras I will do them at £6 each (without fuss), and also patent my idea (which is in practical use since September 1, 1905). Surely not very costly. Kindly remember, also, that the photographic lens is not the same to-day as sixty years ago, and apply that to the one-exposure camera of to-day and sixty years hence.

I am inclined to think that you edited last week's colour columns with the intention to challenge somebody to a reply. Complying with this, your implied desire, I hope you grant me pardon for not accepting three exposures in portraiture in three colours as best.—Yours faithfully,
OTTO PFENNINGER.

September 19, 1905.

[Speaking on the basis of what has actually been done in three-colour work, we can only adhere to our belief that the three-exposure methods have hitherto yielded the best results. We cannot dispute the theoretical superiority of the one-exposure camera, and we are convinced that eventually it must supplant the system of successive exposures. But we were writing of the methods of successful colour workers as we have known them.—EDS., B.J.P.]

RETOUCHING BY NIGHT.

To the Editors.

Gentlemen,—I do not know what the Bruce apparatus is like, or what it costs, but I know that with a white opal globe, 9 in., costing about 1s. 3d., and an ordinary double-wick petroleum lamp, I can do my retouching as comfortably as by daylight, and in winter I seldom use anything else.

The lamp and globe are placed in the retouching desk in such a position that the light from the globe strikes through the negative.—Yours truly,
OTHELLO.

MESSRS. W. H. HUDSON and W. T. D. MAKEPEACE, trading as Hudson and Makepeace, Birmingham, photographers and dealers in photographic materials, have dissolved partnership.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

E. T. Connold, 7, Magdalen Terrace, St. Leonards-on-Sea. Photograph of the Rev. E. N. Bloomfield, Guesting, Hastings.

A. J. Sanders, 18, Mill Street, Bideford, Devonshire. Photograph, Hoggs Corner and Totten Hall, Bideford.

J. Seckington, Willoughby, Rugby. Photograph, Postcard, showing a man riding a pig.

J. H. Willman, 6, Cromwell Terrace, Eastney, Portsmouth. Photograph of Lunch at R.M.A. Sergeants' Outing, Rookesbury Park, August 24th, 1905.

Criticism of Retouching.—Readers desiring criticisms of their retouching should send two prints from three negatives, in each case, one before and one after retouching. The prints should be on glossy paper, and the subjects, an aged person, a young man or woman, and a child. It is impossible to give useful criticism upon the evidence of a single print.

E. R. (Lewes).—There is no demand among makers. Occasionally a small advertisement will find a buyer for them.

A MIDGET QUERY.—I will hask you a kvestin, of you dont mind to anser me. I hav by a camera for midgest, she was whit 9 lenses of a plat cabinet. The midgest was very small and I mandet from a cabinet plate of a plate 5 x 7. the midgest shal caver oll the plate. The lenses cavert all the plates, but the midgest very good, but det is not the right proportion in the midgest. Some midgest is bigger, and some—is smaler. Will you kindle do me the faver and anser me in the fast number of your jurnal wot shel I do, the shtamps sell be right.—ISAACK.

We are not quite clear as to our correspondent's inquiry, which we print literatim and verbatim, but apparently the lenses of his camera are not all of the same focal length.

F. JOHNSON.—Our letter in reference to the copyright is returned to us "not known." We cannot say whether the copyright is registered in England. Your only course is to inspect the register at Stationers' Hall, London E.C.

THERMOMETERS.—I should esteem it a great favour if you could let me know the kind of thermometers they use for testing the temperature of solutions, and where I could procure one. Also how much do you think I ought to pay for an ordinary wall one to tell the temperature of the dark room to be correct.—L. SERGEANT.

About 2s. from any chemist, or from Baird and Tatlock, Cross Street, Hatton Garden, E.C. You can get a house thermometer for about a shilling.

VARIOUS.—1. In your opinion, is self-toning paper as permanent as that toned and fixed in separate baths? 2. Do you consider gaslight papers, Velox and the like, as permanent as the

ordinary bromide papers? I do not like the acid fixing required. 3. Why will not my silver washings precipitate, although both salt and hydrochloric acid have been added? It seems to me they used to go down all right, but lately have been very troublesome.—OTHELLO.

1. Yes, provided they are thoroughly fixed. Fifteen minutes in a bath of 3 oz. hypo to the pint of water is not too long.

2. Yes. The acid fixing-bath is not absolutely necessary, but it cannot be regarded as a source of impermanence if fixation and washing are thorough. 3. We cannot say, in the absence of information as to papers, etc. If salt will not precipitate the silver, certainly "liver of sulphur" will, but you should first add to the washings enough sodium carbonate to cause the bulk to turn red litmus paper blue, otherwise the addition of the sulphide will produce sulphuretted hydrogen gas.

PHOTOGRAPHS OF SWALLOWS.—I require a photograph of a swallow in flight. Can you tell me from whom I am likely to obtain one?—G. H. STRINGFELLOW.

Probably from R. B. Lodge, Enfield, Middlesex, or Chas. Reid, Wishaw, N.B.

VIGNETTING.—I have read with interest two articles in your journal on "Vignetting," and in both cases vignetting with a brush is referred to. I must plead complete ignorance of this method, and should be much obliged if you would enlighten me as to the way in which to go to work.—M. D.

You will find the method described in the first article in our issue of August 25.

INTENSIFICATION, ETC.—1. I intensified some negatives with an old bath of mercuric chloride and ammonia. The bath was somewhat exhausted, and did not effectually bleach them, and there are stains on the negatives. Please say how I can get them cleared; some look like silver stains. 2. I have a number of prints which are too dark. Can I reduce them safely in any way?—P. O. P.

1. It is more probable that the stains are due to traces of hypo left in the film, and there is no remedy. 2. Presuming that the prints are P.O.P., the following is a good reducer:—A: 10 per cent. solution of ammonium sulphocyanide. B: 10 per cent. solution of potass ferricyanide. Add 100 minims of A and 10 minims of B to 1 oz. of water.

RETOUCHING (Reply to R. H. C.).—The evening-dress study is very fairly retouched, being soft and well modelled—but still open to further improvement with finer working and gradation. The girl is not up to the same level, and is flat and ineffective. You should have sent us prints of both of these before retouching as well as after; otherwise how is the preservation of the likeness to be judged? The man is too weak and effeminate in appearance, and should have received stronger treatment. You can greatly improve your finish by leaving the shadows in more; and, when working the larger heads, draw further back from them, and cultivate either the bold, running-line method, or an easy and soft cross-hatch. Do not leave severe or sharp edges of lighting. With a little more thought and care you should turn out good work.

TITLES ON POSTCARDS, ETC.—1. Could you tell me how I can stamp the names on negatives, so as to print white lettering on the postcards? I want a quick and inexpensive way. Are there any rubber stamping outfits sold, and, if so, do you think them suitable? What do you advise? 2. Could you also tell me what would cause the whites in photographs, printed on postcards, to turn a pinky colour, between the toning solution and the fixing while they are washing? The last batch I did, about forty to seventy, I did not wash until complete, but placed them in a bath with common salt; then, after com-

pleting toning, I washed well and fixed; they did not discolour. What do you think the reason of their discolouring, and how can I prevent them? Have I done the best thing? PHOTO.

1. The "Nameit" lettering outfit, obtainable from your dealer, is as simple and quick a method as any. 2. Traces of hypo in the water between toning and fixing. The prints are very sensitive to hypo at this stage. There is no objection to the salt bath, though we think it is not an infallible preventive of the defect.

TITLES ON POSTCARDS.—Can you tell me how to name a postcard in black letters on a white ground as on the enclosed specimen?—O. W. S.

The titles are set up in type by a printer, and a negative made to the scale required on a photo-mechanical plate. A portion of the negative to be named is scraped away, and the wording transferred to it by the usual stripping process.

A READER FOR FORTY YEARS.—If the stain is pyro the best remover is Eau de Javelle, made as follows: Shake up 2 oz. of bleaching powder with 1½ oz. of cryst. soda carbonate dissolved in a little cold water. Filter, and shake up the undissolved residue with plain water and again filter. The solution acts strongly on yellow stain. A preparation of this kind which we can recommend is the "Anti-stain" of the Vanguard Co.

FIREPROOFING, ETC.—Kindly answer the following:—(1) How to make thin calico or gauze fireproof; (2) also how to stain oak camera stand to imitate black ebony.—C. H. F.

(1) Soak in alum 8 oz., ammonium carbonate 2½ oz., boric acid 1½ oz., borax 1½ oz., water 2½ quarts; (2) give several applications of logwood chips digested in water. Add to the decoction one or two nutgalls and some sulphate of iron, and apply two further coats.

W. K. MASSEY.—"The Half-tone Process," by Verfassor (Hiffe and Sons, Ltd.).

CHARLES MARSHALL.—1. We should try Carl Hentschel, Ltd., Fleet Street, London, E.C. 2. Stopping down, unless to a point which would enormously prolong exposure, will not help you. The lens is not achromatic, and after the enlargement has been focussed the easel must be moved in a little, the exact distance being ascertained by trial. Why not get a cheap portrait lens which is not chromatic?

RETOUCHING (PAT.).—Your retouching is second-class only. The shadows under the eyes are not well balanced, and the wrinkles in brow are too much like paint-brush marks—even wrinkles have gradation. Be bolder and better blended in your work, and break the edges of tone into softness. Cultivate the cross-hatch method for a face this size and age. A few strong lessons would do you good and increase your commercial value 100 per cent.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

EDITED BY GEORGE E. BROWN, F.I.C.

THE forty-fifth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,612 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1906 will also consist of 25,000 copies.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1906 will be modified to make it more than ever the book of universal photographic reference. As in the past, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

THE ALMANAC for 1906 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded, and wherever practicable new features of an informative nature will be added.

IMPORTANT NOTICE.—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1st, so as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

EX CATHEDRA.

A "Shop" Convention.

From the report of the proceedings of the twenty-first annual meeting of the Convention of the Photographers' Association of America, given in our last, and previous, issues, it will be seen that the American gathering is a very different affair from that of our own Photographic Convention. In America the annual meeting is for solid business purposes, where the main object of the members is, if we may use the term, to "talk shop." In the States there seems to be more fraternity amongst professional photographers than in this country, and at the Convention much of the time is spent in considering trade questions to the mutual benefit of all assembled. The photographer American freely gives his methods of conducting his business to his *confrères*. Evidently several of the photographers of America attach far more importance to the reception room and the lady who presides over it than do their brethren in this country. Mr. Rockwood of New York, in his paper, says: "The reception room is, after all, allowing that the standard of the work is correct, the keynote of any photographic business. Here all the honour (and profit) lies. . . . The next matter of importance, without which all fails, is a bright, tactful woman at the desk, unless the owner assumes this rôle himself, and, in my view, no man can take the place of a woman if she is fitted." Other speakers dwelt upon the importance of a competent receptionist in aiding the business. Here in England we fear this point is very much neglected. The office is not infrequently filled by a young person taken as an apprentice, or improver, at a small wage, instead of by a tactful business lady of good address. It may be argued that the business could not afford such a person, but it should be kept in mind that an experienced receptionist can often very materially increase a business by her tact in managing the customers, as well as by increasing the sales, and obtaining orders for enlargements, coloured pictures, or miniatures. We have ourselves been in many reception rooms and noticed how unsuitable was the one in charge of them for the duties to be fulfilled. Some of our professional friends, perhaps, may derive suggestions and information from the candid avowal of their business methods expressed by members of the American Convention.

* * *

Exposing in the Studio.

On the first visit we paid to a photographer's studio we remember the operator exposed with a cap, having it in his hand during exposure, presumably to mark the seconds. We may assume that this method of exposure is now obsolete, unless on the sands at Blackpool or Margate

The pneumatic shutter of the flap type has been in everyday use for something like twenty years, and is a convenience for which the photographer has to thank Mr. James Cadett. Many varieties of this shutter are now in the market, the circular bellows shutter, and two or three roller-blind studio shutters. The great advantage of these exposing devices is that they are silent, or practically so, and that the sitter is consequently unaware of the exact moment of exposure. A few years ago we met a professional worker who used a flap shutter for adult sitters, but preferred the cap for children, claiming that he could replace the cap more quickly than the shutter would close. It is possible that this was the case, and may have been due to the position of the shutter, the flap opening downwards on pressure of the bulb, and closing upwards, when the spring, perhaps weakened by age and use, would not close the flap quickly enough. One point requiring frequent attention in these studio shutters, as indeed in all shutters employing rubber in any way, is the perishing of the teats or bladders. So soon, too, do minute leakages occur in the bulb, tubing or teat, or in the connections and tap used for keeping the shutters open during focussing that if more than a minute or two be devoted to focussing and arranging the subject the flap will slowly close. One well-known flap shutter is provided with a catch which can be turned by the hand, and the shutter is then held open indefinitely. The delay in releasing this catch, however, when ready to expose the plate is a serious one, and we think shutter manufacturers might arrange a rod to pass out of the camera either at the top or side, so that it would be unnecessary to insert the hand in the camera.

* * *

Rapid Working in Child Portraiture.

Most particularly is this a serious matter in child and animal photography. With portrait lenses working at $f/4$, or even $f/3$, the depth of focus is so slight that very little movement backwards or forwards gives an out-of-focus picture. Where children are photographed at their natural occupation—playing with toys—as they should be, it often happens that after the image has been sharply focussed, the time occupied in closing the shutter and moving the slide into the place the screen occupied, and then drawing the shutter of the slide, is sufficient to allow the child sitter to get quite out of the field of view. Probably the extreme conservatism of photographers is responsible for the fact that no form of reflex camera specially adapted for studio lenses and studio work has been placed on the market. Such a camera, with a simple form of focal-plane shutter, giving exposures of, say, $\frac{1}{2}$, $\frac{1}{4}$, and $\frac{1}{8}$ second, might readily be constructed and used on a stand sufficiently low to allow the operator to easily inspect the image on the top. In addition to the advantage of being able to expose as soon as position and arrangement were satisfactory there would be the non-inverted image characteristic of the reflex camera. The camera could be so constructed that the mirror might be fixed out of the way if focussing in the ordinary way was required, but probably better results would be obtained if the ordinary studio camera were retained for much of the adult portraiture.

* * *

Some Record Prices.

We referred in our last issue to some of the prices fixed for pictures at the Salon, and alluded to the work of Mr. Alvin Langdon Coburn, for whose platinotype portraits of celebrities five guineas each is asked. It will, no doubt, be news to those workers who are in the habit of submitting portraits to the editors of illustrated journals, and it may also interest the

editors to whom such works are submitted, to know that Mr. Coburn frequently secures the sum of ten guineas as a reproduction fee for some of his pictures. This sum is paid for reproduction in one issue only, and is not for full rights. Many of Mr. Coburn's portraits have appeared in the "Century Magazine."

* * *

Another Celluloid Accident.

Although celluloid has been in use for many years for different domestic purposes, it is not until the last two or three that it has become noticeable for its dangerous properties. Last week another disaster was added to the list of accidents recently chronicled. A telegram from Vienna says that for the third time this year a great explosion of celluloid has taken place there. Two workmen were killed and twenty others seriously injured, and the entire buildings were destroyed by fire. It will be remembered that two or three cases of ladies having been badly burned through the ignition of celluloid combs have been mentioned lately, and it is curious that, according to the report, the explosion in Vienna occurred during the operation of polishing combs. Hitherto celluloid has not been looked upon as an explosive, though it is highly inflammable, and until fuller information is received many will doubt whether the disaster was really brought about by an actual explosion and not by the violent combustion of the celluloid. Celluloid dishes are in very general use in photography, and we have never yet heard of any accident arising from them. Some kinds of celluloid are more inflammable than others, and some scarcely at all by reason of the large amount of other material mixed with them. Still, it is well to be careful when dealing with celluloid in any form.

Portraits at the R.P.S.

In our first notice of the R.P.S. Exhibition last week we referred to many of the portraits hung in the pictorial section, and we propose dealing at length in an early issue with the professional section, which is this year unusually interesting and instructive. As this more detailed review will not appear until the period during which the gallery is open has half elapsed, we would take the present opportunity to urge upon professional workers, both in the metropolis and within easy reach of it, the desirability of paying a visit, if only for the sake of seeing the section most closely connected with the bread and butter side of photography. By way of incentive we may say that the display shows almost all kinds of professional work, and that the old-fashioned style of portraiture is as well exemplified in the show by the well-known and honoured firm of W. and D. Downey, as is the most modern work by the exhibit of William Crooke.

Cloud Effects and Cloud Negatives.

The end of September is here, and many photographers have had their annual holiday with the camera, and will do but little more outdoor work this season. It may be well to remind some of our readers that the present time is an excellent one for obtaining photographs of clouds, either as cloud studies or to use in combination printing with landscapes taken earlier in the year. There is one thing about the photographing of clouds that does not apply to landscapes and similar subjects, namely, that they may be obtained almost anywhere. From an upper window or housetop of the suburban dwelling excellent cloud negatives can frequently be secured, provided the outlook is free from telegraph or telephone wires, hence

we have the opportunity of securing a great variety of effects without even leaving home. Plates or films left over from the holiday outing, instead of being, as they sometimes are, left unused and allowed to spoil, may be profitably utilised for the purposes indicated. The mistake is often made, when developing cloud negatives that are intended for printing in to landscape subjects, of making them too thin and phantom-like, with the result that they, when printed, do not tone to exactly the same tint as the other portions of the picture. When negatives as cloud studies only are required, the camera may be pointed much more toward the zenith than when the clouds are wanted for printing-in purposes. This is also an excellent reason for securing fine sunset effects. For this work trichromatic and backed plates are an acquisition, especially those sensitised with dyes of the eosine series, and more particularly sensitive to the yellow rays. With such, the yellow screen may usually be dispensed with, as the light itself is generally of a very yellow character at sunset.

* * *

Another Red Book" Light.

As announced in these pages a few weeks ago, the meeting arranged by the R.P.S. for members of the affiliated societies takes place to-night (Friday). If the meeting is as well attended as it was last year the Chairman of the Affiliation, Mr. C. H. Oakden, who will address the delegates and members, will have reason to congratulate the organisation on its continued vitality, and the interest taken in its work. It may be argued in certain quarters that this annual gathering of the clans is of no particular benefit to anybody in particular, but with this we cannot agree. The meeting not only gives the members of societies situated in all parts of the kingdom an excellent excuse for coming to town to see the exhibitions, but by bringing the delegates of the societies together the discussion of the affairs of the affiliation which inevitably ensues, is not only good for that body as a whole, but new ideas become circulated among the societies individually through their delegates. Friendly relations are likewise fostered between the parent society and the affiliated ones. The fact that only members of the Royal and affiliated societies are admitted to-night (on production of the Red Book) is a step towards assisting the friendly feeling among the visitors, as everyone will know that everybody else present is a duly authenticated member of the organisation. The doors will be open at seven o'clock, and during the evening, in addition to Mr. Oakden's address, the 1905 Affiliation prize slides will be shown.

Certificates for Industrial Chemistry.

The Institute of Chemistry, which for nearly thirty years past has laboured, and not in vain, to exalt the status of the professional chemist, has taken a new step in the granting of diplomas for proficiency. Hitherto the Institute's examinations have been framed as a test of candidates' abilities in analytical chemistry in one or other of its branches and its diplomas of A.I.C. and F.I.C. have become recognised by municipal, Government, and other bodies as proof of qualification. The Institute now extends its examinations to include industrial applications of chemistry, and will test candidates in regard to the control of plant, the application of power and heat, and in other branches of knowledge which a chemical works manager in his varied capacities of engineer, clerk of works, and architect, as well as chemist, must know something about. In thus recognising the technics of chemical manufacture the Institute helps to cement the

bond between the chemistry of the laboratory and that of the works, and we applaud the inauguration of their scheme for the reason that the photographic manufactory, no less than any other, is destined to benefit by the services of men who can add the qualifications of technical managers to their acquaintance with photo-chemistry and the practice of emulsion making. Under the Institute's scheme the new examinations are open to Fellows and Associates of one year's standing.

PRINTING PROCESSES.

XIII.—BROMIDE PAPER.

THE development of a bromide print calls for as much attention as the development of a negative, and, probably, a little more care in manipulation. With a correctly exposed plate, the action of a normal developer carried as far as it will go will give a good negative, but with a bromide print it must not be forgotten that a somewhat different result is aimed at. The quality of a negative is judged by transmitted light, the bromide print has to be seen by reflected light, and although the development may be apparently carried as far as possible, the density of the deposit has to be entirely different. The difference between the thickness of the emulsion on a dry plate and that on bromide paper allows this to be accomplished with the least amount of trouble, and, although development can be pushed sufficiently far with a bromide paper negative to secure considerable density by transmitted light, the deposit is still extremely weak compared with that of a fully developed plate.

In the development of bromide paper for the purpose of obtaining good black and white prints, the chief qualifications to be desired are:—Purity of the whites, absence of stains, and a deposit of good colour. The purity of the whites is assured—assuming freedom from light-fog, by not forcing development, and by the judicious use of a small quantity of bromide of potassium in the developer, correct exposure being in every case a *sine qua non* if good black and white prints are desired. Stains are avoided by the observance of extreme cleanliness as regards the developing dishes, measures, etc., and in avoiding contamination with hypo.

Bromide paper permits of enormous latitude in the length of exposure, the difference being compensated for by adjusting the developer to suit; but, and this point is not always grasped by bromide workers, the colour of the image will alter immediately the correct exposure is departed from. Correct exposure and normal developer make the only possible combination for giving the best black and white prints. As soon as the exposure is increased, necessitating the addition of bromide of potassium in varying quantities to restrain development, and to steepen the scale of gradation, the colour of the deposit assumes an appearance distinctly different from that given with the normal developer and correct exposure. Instead of a good black, unpleasant, rusty greens are produced. In negative work this is of no moment, but when the developed image is to be seen by reflected light, backed up with white paper, the bad colour is most undesirable. For certain effects, however, this property of bromide paper to give tones varying from the rusty green mentioned, to a pinky red or brown, by alterations in the length of exposure and character of the developer, can be

taken advantage of. There is no doubt that the image, being metallic silver, is as permanent as the black tones, and, probably, more permanent than many colours produced by various toning processes. We will deal with these variations of development later.

For the production of black tones, therefore, the exposure should always be made to suit the developer, and not the developer to suit the exposure. As the exposure that suits the normal developer for producing the best print is the correct one, this should be ascertained for each negative by trial slips of paper with progressive exposures before attempting to make any number of prints. If this correct exposure is noted, and the light, distance from light, and developer remain constant, the best print that the negative will give can always be repeated at a future time. The time taken to fully develop can also be used as a constant factor. Modifications of development can, however, be occasionally employed to obtain certain desirable results. In the case of an extremely hard negative, for instance, that is, one containing much contrast due to under-exposure and over-development, the rule for correct exposure still holds good for black tones; but the most pleasing bromide print is to be obtained by increasing the exposure—doubling it if necessary, and developing in a normal developer considerably diluted with water. The result of this procedure is the production of a print that is much softer in character than would have been produced by correct exposure and developer of full strength; but, be it noted, no extra bromide of potassium is to be added to compensate for the increased exposure, or no advantage in the rendering of the scale of gradation is given, only an alteration in the colour. With the dilute developer and increased exposure, the colour obtained is a pleasing grey instead of black, but the print has to be removed from the developer at an earlier stage. To get these soft, silvery greys instead of blacks, with a normal negative, it must always be borne in mind to increase the dilution of the developer in proportion to the increase of exposure, and to remove the print before it has acquired full strength in the shadows.

It is often asked: "What is the correct exposure for bromide paper?" The correct exposure is that which permits of the development in the print of the faintest details contained in the densest parts of the negative, and no more.

If an exposure sufficient to allow the light to penetrate the densest part is given to a correctly exposed and developed negative, which is the type we assume is most frequently dealt with, the remaining portions of the negative will receive an exposure that will allow, with normal development, the correct amount of density to be secured in the print. If the gradations in the negative are imperfect, as in the case given above, increased exposure to allow the light to penetrate the dense parts of the negative is necessary, followed by short development in a slow acting (dilute) developer, so as not to clog the parts of the print that have been over-exposed. In a dilute developer used under these conditions, the entire image will appear at about the same time, very thin and weak. The action of the developer is then to build up the deposit in the shadows which have received the full exposure, but not to increase greatly the density of the high lights which have received only just sufficient. The print is, therefore, withdrawn as soon as it is seen that the shadows are commencing to clog, and the resultant image will be of a grey colour.

The dilution of the developer without the addition of extra bromide of potassium can, of course, always be resorted to for correct exposure with a normal negative,

and there are certain advantages in sometimes following this course; but in this case the action is allowed to continue until the image has gained full strength. One advantage of employing this mode of developing is that the image does not lose in intensity in the fixing-bath, as frequently the case after quick development in a strong developer; but gains a trifle in depth and richness in the shadows. More time is also allowed to estimate the progress of development, which is not always easy in the yellow light of the dark-room.

In the case of over-exposed negatives that have been fully developed and are not only dense, but lacking in contrast, the addition of bromide of potassium to the normal developer is permissible without apparently affecting the final colour of the print. The time of printing, however, should, if anything, err on the side of under-exposure, and, as recommended in a previous article (see our issue of September 8), this type of negative, and also one that is flat and not very dense, *i.e.*, over-exposed and under-developed, should be printed at a considerable distance from the source of light, and slow bromide paper should be used.

Whether wetting the print before development is always desirable depends to a great extent upon the worker's methods. With large prints or enlargements it is decidedly an advantage to soak the paper in water before pouring on the developer, as it assists the flow of the latter, and obviates the risk of marks and air bubbles caused by the developer not covering the paper quickly and completely.

With smaller work, provided plenty of developer is used, the prints can be slipped into the developer direct. In any case, the prints, after being in the developer or water for a brief period, should always be passed, face down, over the edge of the developing dish, to remove small air bubbles which are likely to collect on the face of the gelatine. The removal of these before development starts is a point in favour of soaking the prints in water first. The soaking should occupy at least a minute to allow the gelatine to get uniformly soaked, otherwise the development will proceed unevenly, and broad bands of varying depth of tone may appear, especially visible in large prints.

Ferrous-oxalate was at one time the only developer advocated for bromide paper, and, indeed, was the only one really possible. Its claims for recognition in the production of prints of a fine colour have always been very much in its favour; but, latterly, it has been almost entirely displaced by the alkaline developers, and it is of these we propose to treat.

Ferrous-oxalate is still used by some workers, and more than one commercial firm employs it in the wholesale preparation of picture postcards. A ferrous citro-oxalate developer is also in favour with at least one big firm of bromide postcard printers; but the lack of control and the necessary acid bath have practically ousted it from the consideration of most photographers, professional or amateur. Added to this, there is always the tendency to discolouration of the whites following the use of this developer, due to the last traces of the iron salt remaining in the paper. No great advantage appears, therefore, to be gained by recommending its adoption. Of the modern developers, amidol, hydroquinone and metol, used separately or combined, and rodinal can be counted amongst those most in favour; and, indeed, these seem to meet all possible requirements for the ready production of bromide prints of good colour from almost any type of negative. A consideration of their use and tested formulae will be given in a future article.

THE WASTED HOURS.

was recently discussing things with a young photographer who has discovered how hard is the world. Here is his case. Three years ago he gave up his situation—35s. a week—in order to marry. He had saved a little money, and he thought the time had come to buy a business and launch out in life. He bought a business, and found that the prices were fair—when he had a sitter. But for ten solid days his wife was in the little reception-room, and he in his studio, before the first customer appeared—no, brightened! their door. Three years have passed, and they have just hung on. The studio rent has been paid, and they have existed. But he is now studying the literature of free farms in Canada, and next spring he will take his wife and the little two-year-old and try a steerage passage to the north-west.

I once heard a clergyman say (he had a lean living, and eight growing lads) that he would turn all his sons into bakers. Wise idea; he had discovered that people must have bread on 365 days in every year, and that bread-selling was usually a cash transaction. He had had any foolish notion of the superiority of a profession knocked out of him by the logic of hard fact. If genteel occupation meant starvation, then he, for one, preferred "trade."

Waiting.

One of the most hopeless features in the life of a struggling photographer is his helplessness. A day of anxious "loafing" is longer than a week of hard work, and as day succeeds day the situation becomes a nightmare. If only he could dig in the garden, or smash something; anything to work off the accumulated nervousness! But he must be spruce and ready, for at any moment the watched-for sitter may appear.

What is the remedy? Well, if he is a single man, and young, and sees no prospects, there are worse things than Canada. It is better to accept a beating now than after fifteen years more of struggling. If he is determined to fight it through and achieve success, then he must find relief for his nerves in some occupation during these waiting hours. He simply cannot afford to wait for business to turn up—he must set out and make it. There is no one way to push business; different places, different methods. But when a new man enters an overstocked town (where is there a town which is not overstocked with photographers?) and in a couple of years is doing a lot of business at fair prices, there is something in it more than luck. One man may be hail-fellow-well-met with everyone and soon know every man worth knowing in the place. He will annex a certain class of business. Another may be exclusive, and at the same time able to turn out an exceptional class of work, appealing to dis-

cerning people. But there is one thing common to all unsuccessful photographers—they all feel the necessity of getting hold of the people.

Letting the People Know.

Suppose the young people had anticipated the ten blank days, and prepared for them. The first result would have been that they would have felt cheerful, perhaps enthusiastic, instead of despairing. The odds are that the man who sold them the business did so because he could not make it pay. And they, poor children, sat there in blissful anticipation of "something turning up." Probably not one in a hundred of the local residents knew that a new man had moved into the place. Why were they not told?

There are many ways of letting people know. The quickest way to get the names of the people is to use an up-to-date directory. If this cannot be obtained at a free library it will be found in the commercial rooms of the hotels. It is easy to select the desirable names. In many directories street lists are included, and, where not, the addresses are given with the names, and so the wealthier residents can be identified. A letter should have been carefully thought out, and then written to each "desirable." The writing would have filled those blank hours, and the sealed letter, personally directed, could be delivered—dropped in the letter-boxes—by hand. The letters would do their work—if not soon, then later. The cost would have been the cost of stationery only.

And Keep Them Posted.

There are many ways of filling in dead hours, and a man who works brainily will manage to get his name known, and to keep it known. Advertisement always pays, but it need not always be paid for, at any rate with cash. Photography is essentially a luxury, and in choosing among many possible luxuries people generally select that one which is brought under their notice. Every guinea taken may be one which but for this asking for might have gone in quite a different direction, and never benefited the photographer at all.

There are still misguided people who essay photography under the fond delusion that it is an easy and respectable means of livelihood. Such people pay a hard price for their experience, and when they drop out find few sympathisers. But there are others who have been trained to photography, and who understand their craft, but who find that venturing in business is heartbreaking work. To succeed they must realise that work must be got, and not waited for; and that for the getting of it the dreary hours of waiting may be profitably used.

ALEXANDER BRADFORD.

PHOTOGRAPHIC SOCIETIES AND EXHIBITIONS.

SOME NOTES ON THEIR PRESENT POSITION AND MANAGEMENT.

IV.

Reporting.

In the last article a comparison was made between the type of reports submitted to the Press by hon. secretaries and reporters of photographic societies. The kind of report that usually finds its way into the waste-paper basket, or suffers severely from the onslaughts of the editorial blue pencil, occurs unfortunately only too often. The kind that makes interesting reading for the general body of readers, and so attracts attention to the society from whence it emanates, is not so common. It is difficult to explain or understand why good, readable society reports are so seldom produced. Material for making them is

not scarce, and it is assumed that the individuals responsible for their production are gifted with normal intelligence, and fully appreciate the value of publicity in the Press for the well-being of the society. Yet the quite uninteresting type of communication previously illustrated is sent out week after week. The readable, instructive type of report, by its usefulness, not only pleases the editor, but helps to ensure careful consideration of all requests in future. In other words, if the editor and the paper are considered, both will prove of undoubted use in "booming" the society in the future, and their support should be cultivated.

Note-taking and Abbreviations.

The right sort of report, therefore, of which an example was given last week, should be borne in mind by the secretary or reporter when making his notes during the evening meetings. As previously mentioned, a knowledge of shorthand is unnecessary when reporting a lecture or demonstration, but it is nevertheless necessary to follow the lecturer closely and grasp the general drift of his remarks. The salient points of his discourse should be jotted down, and, if the reporter is unfamiliar with the subject, the most satisfactory course would be to look the matter up beforehand in the text-books or journals. An hour or two spent in this manner is far from being wasted. Extra knowledge is gained and a greater interest taken in the lecture. The really useful points are more readily noted, and a part can be taken in the after discussion with more prospect of having something interesting to say. Notes of formulæ should be, if possible, always verified after the lecture by the lecturer himself. Names of chemicals can always be conveniently abbreviated if the ordinary chemical symbols are not familiar. The reporter should make out a list of these abbreviations and employ them whenever necessary. For instance, S.S. can be used as indicating sulphite of soda, P.B. potassium bromide, C.S. carbonate of soda, A.Cit. citric acid; Amm., Py., and Hy. can stand for liquor ammonia, pyrogallie acid, and hyposulphite of soda respectively. Hyd. can be used for hydroquinone and M. for metol. G. will signify chloride of gold, and W. water, and so on. "Equal parts of" can be rendered by a sign such as ||, and other abbreviations will readily occur.

In any case the report should take the form of a précis of the practical points described or demonstrated by the lecturer, even if not new. The lecturer himself will usually draw attention to anything he has to say that is really new, and this should be made the most of. All other information concerning the formal business of the evening should be omitted, although it may be useful for the minutes of the society. Whether these particulars are noted by the reporter or the secretary will be a matter for arrangement.

Exhibition Reports.

While on the subject of reports for the Press, notices of exhibitions may be considered. A great number of British photographic societies now hold an open exhibition as an annual fixture, and there are very few of the 400 or so societies in existence in the United Kingdom that do not have an exhibition of members' work occasionally. This latter type of exhibition is, of course, necessarily limited in interest, and a full report concerning it is usually only acceptable to the local Press. If a notice is sent to the photographic papers the particulars should be general in character, and briefly indicative of the strength of the society, thus:—"Blank Photographic Society.—An exhibition of members' work was opened in this society's rooms on the 4th inst. by the Mayor of Blankshire. The entries number 200, and 40 members contributed. The work is of a high standard, and a selection from it will be made for entry in the R.P.S. affiliation competition." Descriptions and criticisms of the pictures are useless unless very good, and the importance of the exhibition is usually not sufficient to merit the additional space being devoted to the purpose.

Open exhibitions, that is, exhibitions in which there are classes open to photographers in all parts of the country, afford much more scope for reporting, in addition to which the interest in such shows is of greater general extent.

When reporting an "open" exhibition, therefore, the date, place, names of judges, by whom opened, number of entries, and award list can usually be given with every prospect of these particulars being published. If, in addition, the exhibition is a well advertised annual fixture, and includes new work by some of the leading photographers, a certain amount of critical notes on the exhibits may be also included. In any case, these notices are likely to interest a far smaller circle of readers than good reports of demonstrations, so unless some arrangement for specially reporting the show has been come to previously with the editor, a bare record of the facts will be all that is necessary.

A Letter to the Editor.

A point that is frequently overlooked by hon. secretaries and reporters who are anxious for the publication of notices of lectures and exhibitions, especially in the local Press, is that editors of papers usually expect a little courteous treatment in the shape of a letter accompanying the report. Much can be done in securing the attention and good offices of a paper by taking the trouble to write a brief note occasionally to the editor telling him how photographic matters are progressing in the district, and the part the society is playing in local affairs.

The necessity for appointing a reporter to undertake the work that would otherwise fall on the shoulders of the secretary will therefore be manifest, and, as mentioned in a previous article, a great deal of the success of the society will depend on the work undertaken by this official, who ought to find a place in the list of officers of every society with any pretensions to success.

A final hint to both reporter and secretary, and that is, when communicating to the papers or writing notices for home use, always write plainly and legibly.

The Council.

It will have been noticed that no special mention has yet been made of those members of every photographic society who constitute the committee or council. This necessary part of the constitution of every association should be of extreme use in backing up the efforts of the secretary. Unfortunately, in many societies the council includes members somewhat inflated with a mistaken sense of the responsibilities of their position, and they are apt to cause discord if they are in any way reminded of the fact. Although they may advise a certain measure, and meet often to discuss affairs of state, it rests with the secretary to test the practicability of the motions, and as he is, therefore, the executive element in the success or failure of any progress, he should have a fairly free hand. "Many heads are better than one," may be the motto of the committee-man, who may also be a busybody, but "too many cooks spoil the broth" will probably be the thought of the secretary who finds himself hindered at every turn by the meddling interference of a too conscientious council. Either trust the secretary to use his own discretion in a great number of matters connected with the welfare and progress of the society, and to a certain extent give him a free hand, or else elect a new secretary. The council's function is that of a court of inquiry and appeal in matters vital to the interests of the society, and in any alterations in its con-

stitution, membership, or financial affairs. To expect the secretary to submit every little incident, such as alterations in the programme, or the form of heading of the society's notepaper to a full council meeting would be absurd; and yet this is frequently done, and the secretary is consequently afraid to make any move without first consulting the council, the members of which promptly take advantage of the opportunity to wrangle over the matter, and much valuable time is wasted. Fortunate is the society possessing a president with a strong personality and great tact. Still more fortunate is the society that in addition has an energetic and reliable secretary; but the more fortunate is the society that has a council which is disposed to let well alone and not interfere with work of the secretary and reporter. The number constituting the council, also, has a certain reference to its utility, and it will be found that a small council of about six or eight, with a sub-committee or two for special purposes will do far more work of practical value than a large, unmanageable council of twelve or fifteen members. The entire list of officers ought not to exceed this number

Vice-Presidents and Treasurer.

The vice-presidents and treasurer are also officers to be considered, but as the former consist of either members who have passed the chair, the office being in the form of a compliment; members who are in the running for the chair, or individuals who may be useful to the well-being of the society, and are honorary members only. In any case a vice-president is always useful to deputise for the president in his absence, and should be endowed with some of the qualifications necessary for that office. The functions of the treasurer may be briefly summed up in that he is responsible for all moneys passing in or out of the society. He writes the polite requests for arrears of subscriptions and subscriptions due, and when he gets them sends out receipts. At exhibition time he should have complete control of the expenditure and receipts, and be in close contact with the secretary for this purpose. Otherwise the treasurer has little to do beyond looking forward to presenting a favourable balance-sheet at the annual general meeting.

Next week the question of the weekly meetings and demonstrations will be discussed. "HON. SEC."

THE WEEK IN HISTORY.

The Second Step in Gelatine Emulsions.

On September 7, 1871, as I pointed out in the "Week in History" of September 8, Dr. Maddox's note on gelatine emulsion was published, but little result came from it for some time. In July, 1873, Mr. Burgess advertised emulsion for sale, and the next step forward was the publication of a formula—the first, except Dr. Maddox's—in THE BRITISH JOURNAL OF PHOTOGRAPHY for October 3, 1873. The communication appears over the *nom de plume* of "Ostendo non Ostento," and very complete directions are given for the preparation of an emulsion at once quite certain, and, as the writer describes it, "giving collodio-albumen definition with collodio-bromide rapidity." Twenty grains of sheet gelatine are placed in a two-ounce bottle with an ounce and a half of water, and, after swelling, the gelatine is dissolved by heat and twenty grains of bromide of cadmium added. In another (three-ounce) bottle thirty grains of nitrate of silver are dissolved in one drachm of distilled water and three drachms of absolute alcohol are added, after which, in the dark room, the bromised gelatine is gradually added to the silver solution, showing vigorously after each addition. The formula thus stands, for two ounces:—

Gelatine	20 gr.
Distilled water	1½ oz.
Cadmium bromide	20 gr.
Silver nitrate	30 gr.
Distilled water	1 dr.
Absolute alcohol	3 dr.

If prolonged emulsification were applied to a formula like this in which is a large excess of silver, its uselessness would at once be apparent, but with the short emulsification practised by the earliest experimenters the formula would probably be practicable, although nothing is implied as to the removal of the superfluous salts by washing.

Beechey Collodion Emulsion.

Old workers with collodion emulsions know that one formula—that of the late Canon Beechey—long remained a standard.

The formula first appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY thirty years ago, i.e., on October 1, 1873. Canon Beechey was a student of Colonel Stuart Wortley, whose activity in collodion emulsion I have already chronicled. The Beechey process was Wortley's with modifications, the chief being a preservative of pyro dissolved in beer. The plate, as soon as coated, was washed for a little while in water, and then given its bath of preservative, which was composed of 30 gr. of pyro dissolved in a pint and a half of clear flat (not acid) table beer.

The Later Work of Niepce.

The history of the relations between Niepce and Daguerre has been the subject of several notes in this column, and I have shown that meagre as is the correspondence between the two men it is sufficient to show in what proportion the credit must be divided. But, in other letters of Niepce, we get a light upon what he was doing, and in none more so than in those to his friend Lemaitre, the engraver. Thus, on October 4, 1829, seventy-nine years ago next Wednesday, he was writing of the advances of Daguerre: "When I was in Paris, and even since my return, M. Daguerre has expressed the desire to know more of my heliographic researches. I am, therefore, sending him an attempt, on a silver plate, of a landscape taken in the camera. As I anticipate that it will interest you if only for its novelty, and whatever its defects, I beg you to give me your opinion. You will notice that the landscape is very unsuitable for the process, as the objects are lighted from behind, or, at any rate, very obliquely, during a part of the time, producing naturally a harsh appearance. But you will see from the fidelity with which some details are rendered what the results would be under any other circumstances." In these experiments Niepce was being influenced by the suggestion of Daguerre that it was better to get one perfect result than a number of inferior ones, such as those which were produced by the photo-engraving method devised by Niepce in the early stage of his researches. HISTORICUS.

COLOUR PHOTOGRAPHY WITH PIGMENT FILMS.

THE majority of practical photographers look upon the evolutions of three-colour photography as something outside their sphere of activity, as an interesting struggle to solve the problem of photography in natural colours. Processes of such high excellence as trichromatic letterpress printing, the Lumière transparency methods, the less commercial but highly scientific and valuable colour processes of Ives, Lippmann, Joly, Neuhauss, all those form stepping stones to one ultimate end—photography in colours from nature. Whether the professional photographer may permit himself to look upon a photograph in colour as something more than an interesting curio, that is a question for the immediate future.

Direct colour photography still remains a problem, but indirect and, I may add, commercial colour photography are accomplished facts, for which, to a great extent, the introduction of trichromatic carbon tissues is responsible.

As Hübl says in his excellent work on colour photography:—"The problem of colour decomposition by photographic means can be considered as solved, as, by employing different sensitisers and light-filters, the conditions of sensitiveness can easily be regulated, but the re-composition of the three-colour pictures by means of printing leaves much to be desired. Especially, the production of photo-mechanical printing surfaces is uncertain, if a very accurate reproduction of all the delicate gradations of a negative is wanted, and also the printing process itself lacks that uniformity which three-colour printing requires."

Stripping Pigment Films.

In search of a purely photographic printing method, which allows for a reasonable amount of retouching, and is not subject to the disturbing influences of theoretically incorrect printing colours, I came across the new "Stripping Pigment Films" for three-colour photography, which gave me such successful results that I gladly take the opportunity to offer a few suggestions, which may assist in making this process more popular in professional circles.

Sensitising the Plate.

The *modus operandi* is as follows:—Get a lens which works at a large aperture, and light-filters which are not too deep in colour, but accurately complement the sensitiveness of a very rapid pan-chromatic plate. I prepare my own plates by sensitising a clear working, but not too rapid, dry plate with pinachrom, as follows:—

Sensitising Bath

Pinachrom (solution, 1: 500 alcohol)	2 ccs.
Ammonia	2 ccs.
Distilled water	200 ccs.

After immersing for two minutes, wash the plates under the tap for about five minutes and dry in a drying cupboard. It is essential that the plates are dried quickly. They will keep for several weeks. The lens I use is a Zeiss "Protar" working at $f/8$, the camera an ordinary tripod pattern, to which a Sanger-Shepherd repeating-back has been added.

Formulae for Filters.

The filters are of my own making, and can be prepared by coating very best patent plate glass with—

Gelatine	1 part
Water	40 parts.

which is dissolved by heating.

This gelatine solution must be filtered before use. Now get a large glass plate, level by means of levelling screws and a spirit level, lay on it the well-polished pieces of glass which are selected for the filters, and pour on each of them a given quantity of the gelatine solution, about 10 ccs. per quarter plate. Cover with

another large piece of glass about 2 in. from the coated surface, to prevent dust from falling on the plates, and let dry.

Now make up the following solutions:—

Blue Filter Bath.

Methylene blue ($\frac{1}{2}$ per cent. solution)	20 ccs.
Water	20 ccs.

Green Filter Bath.

Methylene blue N. ($\frac{1}{2}$ per cent. solution) ...	5 ccs.
Auramine G. ($\frac{1}{2}$ per cent. solution)	30 ccs.

Red Filter Bath.

Erythrosine ($\frac{1}{2}$ per cent. solution)	18 ccs.
Metanile yellow (saturated sol.)	20 ccs.

The above dyes are obtainable from Messrs. Fuerst Brothers, London, E.C.

Adjusting the Filters.

The gelatine-coated glass plates are now stained in the above solutions, and, when dry, form the light-filters which should be used in front of the plate. How long the immersion of the plates is to last only the spectroscopic can tell, but it will be approximately five minutes. However, filters adjusted for such plates are now commercially obtainable, and at such a low figure that it would hardly pay the practical man to waste much time with their adjustment, especially if the subject is a new one to him.

As guide to those who are not conversant with the principles of trichromatic photography, I may mention that the negative taken behind the violet filter represents the yellow-printing plate; that taken behind the green light-filter, the red-printing plate; and that taken behind the red filter, the blue-printing plate.

Before, however, colour photography is attempted, the operator will do well to ascertain the relative exposure ratio of his filters. This can be done in the following way. Photograph a piece of white paper, or, better, a grey scale, through the colour-filters. You will find that the plate behind the violet filter will be totally over-exposed before the plate exposed behind the red filter shows any visible action of the light.

The operator will have to correct and alter his exposures so as to get the grey scale of equal density and gradation in all three negatives.

He may find that the yellow printer or blue filter exposure is represented by 1, whereas, the other two require $2\frac{1}{2}$ and $2\frac{1}{2}$ respectively. $1:2\frac{1}{2}:2\frac{1}{2}$: will then be his relative exposure ratio, and if the first exposure is ascertained he will easily calculate the other two.

Having determined his ratio, the work becomes more or less mechanical. The intensity of light can be found by means of an exposure meter, and past experience will tell the photographer what exposures are required. If the light in the studio is powerful, there is no reason why perfect portraits in colour could not be obtained. In the open landscape there is no difficulty whatever. The three exposures made, they are all developed in the same developer, and always treated exactly alike. No doctoring of the one or the other plate is permissible. As the negatives form the foundation upon which the complicated structure of a three-colour print is based, absolutely perfect negatives are a *sine qua non*. The negatives are to be of good density without showing excessive brilliancy. Metol-developed negatives, rich in shadow detail, have given me the best results.

The negatives can be retouched now, although whenever possible, retouching should be avoided. The question of retouching has always come up whenever portraiture in colour has been under discussion. However, the necessity of retouching, provided the negatives are correct, is never so imperative as in monochrome portraiture.

Colour values are accurately rendered, and pigment spots, although not made invisible, are not reproduced with such objectionable inaccuracy as regards tone value as in monochrome. The crowfoot, the pigment spot, the deep lines, all will be there, but they will be reproduced in colour. The negatives are now marked as yellow, red, and blue printers, so as to prevent a negative being printed on the wrong coloured tissue.

Printing from the Negatives.

The Stripping Pigment Films are sensitised in:—

Potass. bichromate	1 ounce
Water	30 ounces
Ammonia (.880)	1 drachm

This bath must be filtered for use, and the films are immersed in it for one minute.

If the negatives are of a contrasty nature the bichromate can be increased so as to make a 4 per cent. solution; in case of flat negatives reduced to a 1 per cent. solution.

It is essential to add sufficient ammonia to the bath to turn red litmus paper faintly blue.

The sensitising is done in artificial light, a pad of cotton wool being lightly passed over the film in order to prevent air-bubbles. They are now laid flat, film up, on a pad of thick blotting paper, and the excess of bichromate bath which adheres to the film removed by blotting.

The films are best dried in a dark-room which is well ventilated, and the drying is not to exceed three hours. If the gelatine should peel off the celluloid when drying, a small quantity of glycerine may be added. It is well to pin the films on all four corners so as to keep them flat and prevent curling up, which makes contact with the negative very difficult.

Whenever the films are dry, they are laid on a piece of glass, film downwards, and the glossy celluloid surface is freed from any traces of bichromate by gentle polishing with cotton wool.

This is necessary, because the negatives are printed through the celluloid, and dust or dried bichromate solution would show in the finished print. As mentioned before, the tissue and the negative are not laid film to film in the printing frame, but on the negative film rests the celluloid film, which is considerably glossier than the coloured gelatine and is easily distinguishable.

The yellow printing negative is printed on yellow tissue, the red on red, the blue on blue.

Daylight or electric arc light can be used for printing, which is done in the same way as ordinary carbon printing, by means of an actinometer. If the three negatives are correctly exposed, the printing exposures will be about the same, although the red print may require a trifle more exposure.

The best way to ascertain whether the exposures are correct is to print trial strips, and, after developing, see that all details are visible in the highest light, but the pure white of the picture must be clear celluloid without any pigment whatever.

Development

After printing, the films are laid for a few minutes in a dish with cold water, and can now be developed with warm water in strong daylight. The best way to develop the films is to place them on pieces of glass and those in a flat dish containing water of a not higher temperature than 85 deg. F.

Rocking the dish will accelerate the developing, but pouring hot water on the film itself must on no account be indulged in. If the water is too hot the celluloid will distort, and registration of the three prints will be made impossible. The yellow print is best laid on a piece of ferrotype plate, as the colour is opaque and the picture cannot be judged by transmitted light.

When the highest lights show no trace of colour and the shadows

are full of detail, the print is again rinsed with clean warm water, fixed in cold water, and pinned up to dry. The prints may now be superimposed on a piece of opal and the effect judged. However, the practical photographer will make half-a-dozen of each, and select the most suitable from which he may get about four good prints. The waste is generally due to careless manipulation and not to defects in the films, which are of high excellence, although the yellow—the makers will pardon me for making the suggestion—still requires their chief attention, as far as improvements are concerned.

Building the Trichrome.

The transfer of the films is also familiar to the practical photographer, being similar to carbon. The white paper support receives the yellow image first. The yellow film is laid in a dish with cold water for about fifteen minutes, then the white three-colour mounting paper is immersed for about one minute, the film floated on to it, squeezed, and left under pressure between filter paper for fifteen minutes, then pinned up to dry.

When dry, the celluloid is stripped off the yellow print and the latter freed from the coat of india-rubber by rubbing the image with a pad of cotton wool charged with benzole. Next, the blue print is transferred on to the yellow, but it will be found necessary to coat the print with gelatine to make the blue adhere.

The following solution is made up:—

Gelatine.....	30 grains.
Warm water.....	30 ounces.

To the solution add

Chrome alum 10 per cent.....	½ ounce.
------------------------------	----------

The yellow print is immersed in cold water, and as soon as it presents a flat appearance, put on a glass plate covered with gelatine solution and registered by gentle movement of the blue print. Now squeeze, leave under pressure for fifteen minutes, hang up to dry. Strip the celluloid, clean again with benzole, immerse in water, coat with gelatine, transfer the red print, etc. Last of all, the finished colour print is rubbed over with benzole, trimmed, and mounted like an ordinary photograph. The prints can now be printed and retouched with colour obtained by dissolving the coloured gelatine of the tissue.

Is the Process Commercial?

My description of the process may, perhaps, indicate a very complicated and expensive procedure, but this is certainly not what I wish to convey. The process, if worked systematically, is perfectly simple, provided the negatives are correct. I repeat, if worked systematically there is no reason why portraits in colour should not form a lucrative branch of our ordinary portrait photography.

These colour prints have been pronounced by prominent artists as little works of art. They present a depth of colour only equalled by oil painting; they present a purity of colour unknown to the trichromatic photo-mechanical worker, and—here I speak from experience as a practical portrait-photographer—the public are charmed with them. A West End studio, equipped with competent men, working with the latest appliances, high prices and an art-loving clientèle—and photography in colour will be established.

I wish to acknowledge the kind assistance given me by the Rotary Photographic Company, who are the makers of the films, a help which, extended to other experimenters, will materially assist in bringing about a welcome change in professional portrait photography; and last, but not least, will introduce into our studios a class of workers who will compel the old hands to “wake up.” It would mean a general revival of portrait and landscape photography, perhaps better times, until competition will cut the high prices which would have to be demanded for this class of work. However, for a long time to come, photography in colours would form a monopoly of our very best workers, best in an artistic as well as in a technical sense.

HENRY O. KLEIN.

THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

SECOND NOTICE.

CONTINUING our observations on the work in the pictorial section at this year's R.P.S. show, one of the pictures that will immediately attract attention on entering the West Room will be C. B. Howdill's large print "Finishing the Plaque" (106), the plaque in question being that recently awarded at the Northern Exhibition at Leeds. This print is the largest in the room, is of a very rich colour, and appears to be a toned bromide. The fact that it is large adds no great merit to it, and probably the representation of the modeller at work would have been made a more striking picture if on a smaller scale. At present it appears to the visitor as being much the same print that Mr. Howdill showed last year.

Three other large prints that will also call for attention are contributed by W. Thomas. These also appear to be toned bromides, but the colour is rather too "foxy" to be entirely satisfying. "Nature's Slumber" (171) is the best of the trio, and is a strong, well-composed woodland scene, the grouping of the tree trunks and the lighting making a notable composition. "On the Evening Tide" (242) is a vigorous, almost theatrical, effect of light and shade. The sails of the fishing boats, however, strike us as being too black and solid. "A Sea Banquet" (216) is a fine rendering of gulls pouncing on to some morsel in the sea. The unpleasant colour referred to is very pronounced in this print. Near by is another rendering of gulls in flight, by F. J. Mortimer. "The Shoal" (214) is a portrayal of tumbling, seething rollers breaking over an almost hidden shoal; gulls are flying overhead, and the composition is materially aided by their presence. In addition to the large seascape by Mr. Mortimer, mentioned last week, "The Brooding Terrors of the Storm" (119) and "A Twin Roller" (205) are both good examples of this worker's powers for picturing the sea in its angry moods. Three delightful little figure subjects are shown this year by T. Lee Syms, "Robinson Crusoe" (191), depicting a small urchin stretched in comfort on a wooden settle and intently devouring the contents of a large book, presumably "Robinson Crusoe." Both the motif and execution of this picture are of the best. "Too much study is a weariness of the flesh" (100) is on similar lines, and tells its story well.

E. T. Holding's work is usually sound, and "The Student" (113) is very characteristic of this worker's method. A little girl with a book huddled on the floor in the corner of a room. The effect secured by pointing the camera down is not unpleasant. "Study of a Head" (209) is a successful attempt in red gum. The extremely brilliant hue of the pigment employed combined with the curious colour of the paper on which the print is made produce a somewhat novel result. Near by is one of the other brilliantly-coloured prints in the exhibition. This is a bright-green effort by J. C. Warburg. "Fairy Clocks" (189) is the title, and its colour probably compels more attention than the subject. It is, nevertheless, a clever little study of vegetable life, and should have been more centrally hung. Mr. Warburg's "Brunnsparken, Gothenburg," is another instance of his versatility. Strong, sunny, and of good composition, this approaches more the realms of the conventional than is usual. "Rocks and Wrack" (235) is another delicate seashore study, containing pleasing lines, but is not so good as "Surf," already referred to. Notice should have been drawn last week to Dr. Otto Rosenheim's "Portrait of a Collector" (27). This is one of the best gum prints in the show. Apart from this, it is good both as a portrait study and as a composition. We have already mentioned Arthur Marshall's "Shade." His "Student" (22) is a capably managed interior, with a seated figure—a little Dutch girl. The lighting is very fine, and the composition very complete, although inclined to be a trifle scattered. "In one day it opens its blossoms and in one

day it decays" (9) refers to the flower held by the young woman depicted in this picture. We do not care for this arrangement quite so much as Mr. Marshall's "Devotion" of last year, to which it may be said to form a companion picture. "The Tombs of the Bathers" (62) has a familiar appearance. It is because of its similarity to a previous much-exhibited picture by this worker, "The Last Sleep," but is not so good. Rudolf Eickemeyer, jun., has in "Costume Portrait" (43) a print of splendid quality, in spite of its somewhat dirty texture. This is the best of his three contributions. "In the Berkshire Country" (156) and "The Toadstool" (213) are, however, worthy productions of this clever worker.

J. M. Whitehead's exhibits vary somewhat in quality this year, although they all evidence masterly technique. In "The History of Many a Winter Storm" (67) the composition strikes us as being weak. This appears to be due to the central object, an old and weather-beaten tree, being placed too low. "Until the Daybreak" (90) has an unpleasant appearance reminiscent of the old-fashioned mourning card. "Solitude" (114) and "The Sleeping Fields" (194) are the two best of his contributions. W. T. Greatbatch has several of his successful experiments in dealing with problems of sunlight and shade. "In Old Lisieux" (116), "An Old Alley, Lisieux" (82), and "Courtyard, Lisieux" (201) are clever examples of his work. "Dieppe Market" (117) is also noteworthy, but is rather of the "snapshot" type, and is more indicative of fortuitous arrangement than deliberate composition. The fine quality of "Evening, Caen," we have already referred to. J. Page Croft's "Indifference" (103) is one of the best things this apostle of "gum" has yet produced, and he has found an apt title for his second print in "Inscrutability" (204). The pictures by J. Cruwys Richards are always interesting, and in "Beatrice" (44) and "The Grace Cup" (97) we have two excellent examples of the work of this "Link." He has had the wisdom, however, to enter his third print, "A Woman of Connamara" (356), a portrait study in multiple gum in the scientific and technical section. John Hepburn's two genre studies are extremely good, "The Wee Invalid" (63) being a worthy follower of "The Doctor" of last year. James Gale's prints are not so striking as some we have had from him. "A Dutch Interior" (7) is rather complicated, and the figure is not sufficiently detached from the remainder of the picture. "Sunshine and Smoke" (69) is inclined to be dirty in tone, but is a good composition. Dr. T. G. Crump's "Passing Clouds" (70) is almost overdone so far as the clouds are concerned. They are very massive and solid-looking, and the effect is rather top-heavy.

A. H. Blake's "Sunlight on Whitewash" (37) is also at the Salon, but this appears to be the better print. It is an excellent picture, made out of very ordinary materials, and should serve as an object-lesson to would-be picture-makers who complain of having nothing to photograph.

Wm. Rawlings and G. J. T. Walford have each some typical work on view, the former's "The Lonely Moor" (78) being a notable composition, and, as a good arrangement of lines, worth careful inspection.

One of the finest snow scenes we remember having seen is "Approach of a Winter's Evening" (84). This is by Clarence G. Dudley, an American worker, and it may be taken as a model for those who wish to render the tone values of a "snowscape" correctly. As an example of unnecessary handwork, John H. Hodge's "Bringing in the Pilchards" (243) is noticeable. The high lights have been obviously scratched away, and what would otherwise have been a remarkably good little picture is spoilt. "A Study in Straight

"Lines" (229), by G. L'Epine Smith, bears out its title admirably—trees, a church tower, and reflections—but the lack of detail is rather too pronounced. Douglas English's "Study of a Swan" (237) is a clever specimen of instantaneous photography, but would probably receive more appreciation in the technical section. Carle E. Semon's "In Costume" (31) is not so good as "The Gown" (118), although both are good examples of this American worker's figure studies. The latter is a very satisfying composition, but it is not clear whether the title refers to the gown worn by the lady or to the gown we suppose is hidden in the chest of drawers.

Joseph Appleby's "Through the Pine Trees" (71) is a large and luminous woodland study, the cast shadows being cleverly managed. His other picture is also big, and the lighting is not so unreal as has appeared in Mr. Appleby's previous pictures of sand-dunes. The title "Breezy, Bright, and Bracing" suggests Blackpool. H. P. C. Harpur's "The Bridge" (230) is an effective result obtained with simple materials, and Cavendish Morton's figure studies are straightforward examples of good photography combined with clever posing. Wm. A. Clark's architectural study, "A Norman Processional Path" (127) is in this photographer's well-known style, and is as good as anything he has yet done. Among other pictures that may be singled out for special mention are:—"In Robin Hood's Town" (15), by Rev. H. W. Dick—a fine effect of sunlight; "Off Duty" (58), by James Shaw—a most convincing "costume" group. "The Madonna of the Blackthorne" (49), by Sidney Vacher—somewhat incomprehensive at first, but very good; "The Burden of the Sea" (54), by E. B. Vignoles and Lieut. P. S. Greig, R.E.—two nudes, one of which is apparently intended to be a corpse. Not at all well done or in good taste. "A Water By-way" (77), by Mrs. H. Wootton, is a delightful Venetian scene, very suggestive of one of Percy Lewis's studies. "In Lisieux" (107), by P. Bale Rider—a very sunny little picture, and good composition. "Moribundus" (120), by J. Fielder Haden, a striking study of an old wreck. The light effect in this picture is very strong. "Tugging Home" (125),

by W. Clayden, is a very atmospheric shipping study, and dainty in tone. "Bereaved" (129), by E. H. Hazell, is somewhat too dramatic and the strained look upon the model's face rather repels after a time. "While London Sleeps" (133), by G. L. A. Blair, is a good lamplight study in the manner of Paul Martin. "Shrimpers" (136), by Louis J. Steele, is a clever group of fishermen on the wet sands. The reflections are good in this picture. "Iris" (79), by E. Seymour, is a good example of this worker's flower studies. "Dolores" (87), by P. R. Salmon, is a portrait study rich in tone, but rather ragged in texture. "A Dutch Canal" (137), by James C. Batkin, has a beautiful effect of distance and atmosphere, and Oscar Hardee's portrait study (139) is good, straightforward photography. Harold W. Lane's "Shoeing" (143) gives a good representation of steam and smoke, and in "Fragility and Strength" (151) W. A. I. Hensler has a composition of heavy trees and light woodland flowering grasses that lacks unity, and is somewhat top-heavy. His "Golden Gorse" (218) is, however, very fine in every way, and is as good a specimen of clear landscape photography as anything in the gallery. "On the Frozen River" (158), by John Chislett, contains some dainty silvery tones, and Francis J. Phillips's "Groote Kerk" is a clever interior, but he has rather spoil the tone of the latter by darkening the body of one of the figures. "A Cherry Orchard in Spring," by Miss Agnes B. Warburg, is a nice rendering of spring foliage, but the cold tone of the print suggests snow rather than blossoms. "The Night Express" (173), by R. R. Enfield, is worthy of attention by reason of its impossibility. We will not inquire into its method of production. "In the North Aisle, Norwich" (179), by S. C. Stean, is a good architectural study, of which there are too few in the exhibition.

Space will not permit of further reference to other exhibits in the pictorial section, which, as stated last week, contains as fine a collection of good work as the most captious can desire. The professional work in the South Room will be dealt with in our next issue.

ON MAKING NEGATIVE ENLARGEMENTS.

Large v. Small Pictures.

Now that the exhibition season has fairly started, and photographers are devoting time and consideration to the production of large prints from their small negatives taken during the summer, the following practical notes, abridged from a series of articles by Walter Zimmerman appearing in "Camera Craft," will be of value to many of our readers. Mr. Zimmerman is one of the leading pictorial workers in America, and his methods may be followed with advantage. He says:—"In pictorial photography, if a small picture be perfect, a large one, properly executed, must be pluperfect. There are many circumstances which might appear to give reason for modifying this statement; that the technical quality of the large picture is rarely equal to that of the small one; and that many defects, trifling in the original, become magnified in the large reproduction. Nevertheless, the statement remains exact, for the perfect technical work must be taken for granted in the making of a perfect rendering, and if there are defects in the original it cannot be a perfect picture. The presentation of the work in large size has the great advantage of enabling the artist to remedy defects better than in the small, and the operation calls for all of the artistic as well as technical skill of the photographer. Certain it is that where real merit exists, the attention of the public is given principally to the large work, whether on canvas or on photographic paper.

Methods of Making Enlarged Negatives.

"The rule which we shall adopt here is to explain the process of making large negatives for exhibition photographs in such a way

that there shall be no double printing, on the one hand, and that there need be no modifications by manipulations of prints, on the other. The thing that is desired, of course, with large plates and paper, is to get everything in the negative, so that there need be no masking, shading, or other work upon the print, during or after exposure.

"I will also explain, as fully as possible, a special method of making exhibition negatives by a process which has never before been published, so far as I know, but which, nevertheless, has the advantage of accuracy and extreme simplicity.

There are four ways of making negative enlargements on glass, namely:—1. A contact positive and a negative enlargement from it. 2. A positive partial enlargement, and a secondary negative enlargement. 3. A positive enlargement and a contact negative. 4. A negative made by printing through an enlargement on paper. The third and fourth methods are those which produce the most perfect results, and special attention will be paid to them in this article.

"The most perfect large negatives are those which are made by contact with a positive of the same size, rather than through an enlarging process to produce the negative itself. The third method mentioned in the list is glass contact from glass, and for perfection of technical results nothing can be equal to it. It is, of course, the most expensive way, as two large plates are required, barring failures.

Making the Enlarged Transparency.

Place the small negative, glass or film (the latter between two pieces of glass), in the kit or frame for negatives in the enlarging window.

The daylight passes through the negative, and the lens projects a magnified image on the sliding board or easel. Cut a piece of heavy white cardboard the exact size of the plate to be used, and obtain the size by an approximate focus. If a selected portion of the negative is to be used, that portion only will, of course, be contained on the image projected on the card. If diffusion is wanted from a sharp negative, the precise effect desired can be easily obtained. If an exact reproduction of a diffused negative is wanted, use another negative with sharp lines and focus, then substituting the negative to be used, as previously suggested.

"Pin on the enlarging board a smooth piece of black paper larger than the whole image projected, in order to prevent possibility of reflection or halation. Replace the white card, holding it in place by means of at least four glass-headed pins well driven in, the corners being better, to hold the card firmly, but allowing it to slide up from its position. Take out the card, cap the lens with orange for slow plates and red for fast plates, cut off all light but the developing light at the tank, take out the plate used and place it in position indicated by the pins. In this way the negative will have been focussed, the right portion selected, and the plate is safe and ready for the exposure. The glass side of the plate will, of course, be next to the black paper, and if, for any reason, a reversed negative is desired, such as for single process carbon work, the negative would have been reversed, film side out, in the kit.

Exposures.

"If you have been successful in making bromide enlargements, and have learned the exposure to be given, especially with the negative to be used, the relative exposure for plates will be as follows:—

"For a fast plate, single coated, one-eighth the exposure of bromide paper.

"For a medium fast plate, one-third the exposure.

"For a process plate, the same exposure as bromide paper.

Consideration of Plate Speeds.

"The quality of the negative to be enlarged from will determine to some extent the kind of plate to be used for producing the large transparency, in addition to the density or colour of the negative determining the exposure. The slow plate transparency, normally exposed and developed, will have considerably increased the density and contrast as compared with the original. The operator will be guided by his own preferences in making the selection. On the other hand, with a heavy original, a fast plate, properly handled, will give a transparency in which much of the harshness will have been lost.

"The making of the final negative must also be remembered. A slow plate transparency from a contrasting positive will, under normal treatment, have very heavy blacks and whites in printing from it. A thin, fast plate transparency, and a fast plate negative, will print flat, but full of detail. The photographer who wishes to be supplied for all effects in negatives should have a supply of both fast and slow plates, or else he may prefer to use the medium speed for both positive and negative. It is a prevalent error among professional photographers who make negative enlargements, to have them too dense, and with so much contrast as to give a very hard effect in the prints from them.

Modifications of Exposure and Development.

"A knowledge of exposure and development will render it unnecessary to keep two kinds of plates on hand. It is a well-known rule that over-exposure and weak development tend to flatness and detail, and under-exposure and strong development tend to contrast and harshness. With some expertness in exposure and development, the photographer may obtain in each process the effect that he desires. In making transparencies it is a good rule to give full exposure and full development, as, with a rapid printing medium (the second plate for the negative), there is little difficulty in having the light penetrate

all parts of the transparency. The full exposure and development give the best large reproduction of the original with the least possible loss through the enlarging process. This remark is quite pertinent, for the reason that the transparency is taken out from the developer too soon five times, to where it is once left in too long by the average photographer. It is also a good rule to expose the positive for the high lights, which is equivalent to over-exposing, in order to avoid loss of printing quality.

Developers.

There is also considerable opportunity for individual taste in the choice of the developer. A good metol-hydroquinone formula, diluted with ten times the quantity of water will, with prolonged development, give a positive which is full of detail, and with fresh chemicals, a negative without the yellow stain which is difficult to estimate in exposing for the negative. Pyro will give a very rich and beautiful transparency to look through, but it may not produce such a good negative, on account of the difficulty of exposure just mentioned. In developing the final negative, it is best to use metol-hydro with slow plates, to obtain detail, and pyro with fast plates, to obtain brilliancy. All of this is, however, to be modified by the effect, whether sharp or diffused, low-toned or brilliant, desired in the prints to be made from the negative. Even these effects are again modified by the printing method and paper to be employed.

After Treatment.

After the transparency has been washed and dried it should be examined critically to determine what modifications, if any, should be made to it either to remedy errors or to improve the pictorial effect. If the transparency is backed with a piece of tissue paper or ground glass, it may be seen to better advantage. The modifications decided upon may be made by a competent retoucher, or by the operator, if he understands or will take the pains to learn this kind of work. Intensifications and reductions in part or whole, should be made prior to retouching on account of the coating of varnish used for the pencil work. For a small spot touch the cork with varnish to the place, and with a piece of soft cotton spread it quickly and uniformly as thin as possible. If the whole surface of the negative is to be prepared for pencil work, let a few drops of the varnish fall on the film, and work it out very rapidly and evenly. The coating so prepared will have no effect whatever in printing, which would be the case if the varnish were to be allowed to dry on thick or in patches. The surface is ready for the pencil almost immediately. Retouching on transparencies requires less skill than on negatives, in which the work has to be done in reverse as to light and dark parts. To remove any part of the retouching, rub in a drop of varnish as at first. For darkening more of the surface at one time than could be readily worked over with the pencil, an extremely weak solution of red aniline dye in alcohol may be rubbed on evenly with a wad of soft cotton. For broad effects there is another medium, ground glass varnish, which is to be flowed, not rubbed, over the glass side of the plate. The surface so prepared will take pencil like paper or ground glass. This method is used by some well-known portraitists, who insert backgrounds and other decorations.

A simpler method than any of the above for making modifications on transparencies or negatives is to fasten a piece of smooth, thin paper, such as bond paper, to the glass side of the plate, either by gumming the edges or by fastening the paper to the plate with lantern-slide binding. The paper will, of course, take all of the lead pencil, lampblack, or crayon work that may be needed, and will not change the resulting negative except by slightly lengthening the exposure. Necessarily, any such broad medium is not applicable to the original negative for the obvious reason that any grain or imperfection in the paper would be magnified and intensified.

[The concluding portion of this article will be given next week.—
Ems., B.J.P.]

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes."

The following applications for patents were made between September 11 and September 16:—

TRIPODS.—No. 18,332. Improvements in tripod stands for cameras and such like articles. Alexander McLeod, 322, High Holborn, London.

DAYLIGHT CHANGING.—No. 18,413. Improvements relating to daylight changing devices for photographic plates, films, and the like. Neue Photographische Gesellschaft, 7, Southampton Buildings, Chancery Lane, London.

FLASHLIGHT.—No. 18,422. Improvements in flashlight devices for use in photography. Takenari Azuma, 53, Chancery Lane, London.

MOUNTS.—No. 18,522. Improvements in and connected with photographic mounts and the like. John Bower Binns, 18, Southampton Buildings, Chancery Lane, London.

DEVELOPING FILMS.—No. 18,551. Improvements in apparatus for use in developing photographic films. Frank Sugg, 9, Tempest Hay, Liverpool.

MACHINE BROMIDE-PRINTING.—No. 18,629. A machine for the rapid printing of bromide photographs on separate sheets of paper. Leonard Constantine Coward, 66, Brundretts Road, Choriton-cum-Hardy, Manchester.

ENLARGING CAMERAS.—No. 18,700. An improved attachment for use with photographic cameras for purposes of enlarging. Henry Rex Cook, Fort Fareham, Fareham, Hants.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d each, post free, from the Patent Office, 25 Southampton Buildings, Chancery Lane, London, W.C.

DAYLIGHT CHANGING.—No. 19,010, 1904. The invention consists of light-tight flexible sheaths or envelopes, one plate in each, fitted with tabs or other means by which the cover is withdrawn for exposure of the plate. These sheaths are inserted one at a time into the exposure frame, whence they pass to a slide in which the envelope is removed and the plate exposed. It then passes to a chamber in which a certain number accumulate for development. Arthur Augustus Brooks and George Andrew Watson, 23, Tower Buildings, Liverpool.

FOLDING REFLEX CAMERA.—No. 20,384. A folding camera in which a full-size image is obtained by a mirror, which moves into the focal plane on the camera being folded up. The arrangement of mirror *n* is as follows:—The mirror rests upon, and is supported by, the upper of two sets of lazy tongs *l, l*, which are pivoted at their rear ends to the film box, as shown at *p, p*; and, in order that the proper relation may be maintained between the mirror and the exposure opening, through the shutter, the two are connected by attaching a plate of thin metal *q* to the under side of the mirror frame, which has a narrow slot *s* cut in its lengthwise, in which slides the pin or screw-head *t*, which connects the front end of the upper lazy tongs to the pivoted plate connected with the shutter casing *T*, thus guiding and controlling the upper edge of the shutter casing. In order that the bellows may be properly held when retracted in to the position shown in the illustration, which position it assumes during the operation of focussing, a catch *2* is arranged at about the central part of the folding frame *C* adjacent to an opening *3* therein, in such position that when the shutter casing *T* is drawn rear-

wardly into the position shown in the figure, one edge or side of the exposure opening in it will engage with this catch *2*, so that the parts will be held in their then position, but by the insertion of the finger of the operator through the opening *3*,

the parts may be disengaged, and then all will move rapidly upward into the position for exposure. George Washington, of Tompkinsville, Staten Island, Richmond County, New York State, U.S.A.

PRINTING FRAMES.—No. 24,246, 1904. The design of the frame will be understood from the figure and the instructions, the frame being specially adapted to making prints having a border or ornamentation round the photograph. The sensitised paper or card *7* is inserted behind the screen *2*, and the negative *8* is inserted in position behind the cut out portions *3* and *4* and in front of the sensitised card, and, with the parts in the position described, the device may be placed in a suitable frame or holder and exposed. The sensitised card is then removed from behind the screen, and placed in front of it and behind the

tablet *1*, and the negative is removed and an opaque shield *9* of any desired shape is placed in position to protect the print upon the card which was produced from the negative from further exposure. The previous printing operation exposed only those portions of the sensitised paper opposite to the cut-away portion *4* of the screen *2*, the remainder being protected from light by the screen. But the subsequent printing will cause those portions of the sensitised paper not protected by the shield to be exposed to light, and, consequently, a message or inscription, which may be written or otherwise marked upon the tablet *1* will be reproduced and printed in the well-known manner upon the desired portion of the sensitised surface. Kodak, Limited, 57-61, Clerkenwell Road, London, E.C.

TIME VALUE FOR SHUTTERS.—No. 433, 1905. The claim is for a construction of shutter valve such that any ordinary exposure can be readily and accurately obtained. When the shoulders *f, f*, on the various parts are in contact, the tapered nozzle is also in contact with the sides of the air passage, forming an air-

tight connection therewith. When so adjusted the air passage *g, g*, which runs the whole length of the valve, is unbroken, but when the sleeve is unscrewed, as shown at *c*², more or less air escapes around the tapered nozzle (when the ball is compressed)

according to the degree of its withdrawal from the air passage in the stem *d*, thus allowing a very wide variation in the duration of the exposure. Hugh Alexander Crabb, 114, Gleneagle Road, Streatham, Surrey.

STEREO PRINTING FRAME.—No. 24,247, 1904. A frame to provide for properly positioned prints without special attention. The negative is first clamped in position between a clamping plate and the body of a movable carrier, and the paper secured to the lower face of a holder. A system of covers then provides for the positives of negative and printing paper to be reversed, and when the frame is set to work for a given degree of separation the positions can be printed off as rapidly as possible. Kodak, Limited, 57-61, Clerkenwell Road, London, E.C.

DAYLIGHT DEVELOPMENT.—No. 5,022, 1905. The claim is for a development dish with a light-tight cover containing non-actinic-windows, set at an angle to the plate, and a viewing aperture. There are means at one end of the dish for inserting and withdrawing a plate, and an inlet and outlet for developer and other solutions. William Edward Caldbeck Crofton, 1, Lakelands Park, Terenure, Dublin.

New Books.

"Instruction in Photography." By Sir William de W. Abney. Eleventh edition. London: Iliffe and Sons, Ltd. 7s. 6d.

It is very nearly twenty years ago that we purchased our first copy of Abney's "Instruction in Photography." We still recall the sensation of youthful disappointment at its acquisition—the feeling was prompted by the discovery of how much the volume said on topics which in no wise interested us in those days—but the identical work is now the most bethumbed of our library. In contrast with it the eleventh edition is a corpulent volume, and the contents of the later issue shows with what diligence its distinguished author has continuously made it representative of the current photographic science and practice. Yet the present volume is not big. Six hundred and seventy-six pages are not overmuch for a treatise on the whole field of practical photography. The implied compression is one of the book's virtues: it is not a compilation brought together from all sources more or less "edited," but it represents the current knowledge of the craft sifted and winnowed by a man who can claim to have worked practically in every photographic process, and to have left pretty nearly every one of them all the better for his labours. That is the view we have always taken of the previous editions of "Abney's Instruction," and we shall be sorry to see reason to alter it. The present volume is like its predecessors in this respect, though the task of replacing the old by the new must have been a more formidable one than in the case of precedent editions. For the work of identifying the volume with modern methods the author acknowledges the aid of Mr. J. McIntosh, who is thus fortunate in sharing congratulations on the reappearance of this standard English text-book of photography.

THE "Annuaire Général et International de la Photographie," published by Plon-Nourrit and Co., 8, Rue Garancière, Paris (6 fr.), is brought out with the accustomed features of ample illustration, selected articles, and a review of current progress. The most noteworthy of the articles is that on photography by magnesium light, by M. E. A. Martel. The "Annuaire" has the most complete directory of membership in the French photographic societies, but the list of British photographic periodicals stands in lamentable need of revision.

CAMERA WORK.—A copy of the twelfth number of this beautifully printed quarterly has been sent to us, and it amply sustains the high reputation Editor Stieglitz has made for it. The number contains ten gravure reproductions of Mr. Stieglitz's photographs, printed on Japan tissue, and three specimens of the pictorial work of F. Benedict Herzog. These illustrations are probably the finest reproductions yet given in any photographic periodical, and the literary matter is of an equally high standard. The productions of the leading pictorial photographers of America and Europe have been or will be dealt with in "Camera Work." Information respecting subscription and future arrangements will be mailed on application to Alfred Stieglitz, 1,111 Madison Avenue, New York, U.S.A.

New Materials.

"Haystack" Gaslight Paper. Made by the E. F. Stack Manufacturing Co., Sidmouth Road, Leyton, Essex.

A sample of the paper submitted to us by the makers we find to be a gaslight paper of good quality, producing readily prints of good colour and vigour. Any developing formula suitable for emulsions of this class is stated by the makers to be suitable, and certainly we have no fault to find with the way in which it responds to a standard metol-hydroquinone preparation.

Agfa Chromo-Plates. Sold by Messrs. Charles Zimmermann and Co., 9 and 10, St. Mary-at-Hill, London, E.C.

In offering an isochromatic variety of the "Agfa" plates, the makers are fortunate in approaching photographers with the reputation of producing a very clean-working and excellent plate of the ordinary brand. Hence there may be reasonable anticipation that with the added quality of colour-sensitiveness the general properties of the plate will not be impaired. We may not be correct in our surmise that the fine grain and freedom from fog of the Chromo plate identifies it with the ordinary brand of Agfa emulsion, but the fact remains that the isochromatic brand is excellent in these respects. On other grounds it may be signalled out as noteworthy, since, for its speed—it is a very rapid plate—it possesses pronounced colour-sensitiveness. The association of these two qualities in one plate to the degree found in the "Chromo-Agfa" should mark out the latter as fulfilling the wants of those who cry for a rapid iso plate. The plate is extremely rapid, and its chromatic qualities are such that less screening is necessary to secure a given effect. In development, it shows little or no tendency to fog, and it yields negatives of as great vigour as need be made in ordinary work. The following tests, obtained for us, according to our usual custom, by Mr. C. E. Kenneth Mees, B.Sc., will explain better than words can do to the scientific worker the general character of the plate:—

Inertia (H. and D., pyro-soda) .135.

$\gamma \infty$ (density-giving power of the plate), 1.94.

K (velocity constant of development with standard ferrous oxalate developer), .081.

ty (time necessary to obtain the standard gradation of the with the standard developer = the time the plate should be developed), $9\frac{1}{2}$ minutes.

*Opacity (to blue light and an index to the latitude of the plate), 6.

Ratio of $\frac{\text{blue sensitiveness,}}{\text{yellow sensitiveness,}}$ 3.1.

The practical worker can assume from these figures that the general character of the plate is, as we have stated. As we have said, the plate is highly isochromatic for its speed, and among other obvious applications of such a plate we may name portrait work in the studio. The "Chromo-Agfa" plate, we hope, will encourage the practice of orthochromatic photography in the studio.

CATALOGUES AND TRADE NOTICES.

WHEN, why, and how to use orthochromatic plates are oft-put questions at present. There is no better way of answering them than by studying a pamphlet just issued by Messrs. Elliott and Sons, Barnet, in which the practical reasons for the orthochromatic plate are very clearly and succinctly stated. The little book contains a number of convincing illustrations of colour-sensitive plates. It is supplied to dealers for distribution, or sent on receipt of stamp to postal applicants. Every photographer interested in obtaining the best results with colour sensitive plates should write for a copy to Messrs. Elliott and Sons, Barnet, for though the booklet is avowedly produced in reference to the Barnet Iso plate it is none the less a commendable exposition of its subject.

SAMPLES of very tasteful designs in fancy folding slip-in Christmas mounts have been sent us by the Crown Photographic Manufactory, Rotherham. These cards are excellent in every way, and they are, moreover, not expensive. Sample packets of 50 cartes de visite or 25 cabinets assorted with mottoes, blocked in gold, silver, or white will be sent, post free, for 2s. A full price list will be forwarded free on application.

MESSRS. F. HELMRICH AND CO. (late 37, Walbrook) inform us that they have removed to new premises at 158, Aldersgate Street, E.C., where they have extensive showrooms for photo pendants, lockets, prints and frames, etc.

A VERY complete and well illustrated catalogue is to hand from Riley Bros., Limited, of 55 and 57, Godwin Street, Bradford. It contains particulars of everything necessary for the user of optical lanterns. The Riley-Prestwich Projector is also illustrated, and a long list of lecture and general sets of slides is included.

No. 17 of "Fallowfield's Courier" is to hand, and contains particulars of new patterns in Christmas cards. A special offer is made to customers of a new sample set, made up to order, of assorted designs to the list value of 7s. 6d., post free, for 5s.

"HINTS on Lenses for Professional Photographers." Messrs. R. and J. Beck, 68, Cornhill, London, E.C., are offering free a pamphlet, which we can say, from a knowledge of the queries addressed to us, contains much information required by those working in studios. The hints concern length of focus, rapidity, depth, and definition, and thus lead up to the important question of the choice of a lens for portrait use. A series of exceedingly useful tables is included, showing the distances from sitter to lens, and from lens to plate, in photographing busts or full lengths to a certain scale. The tables do this for some forty different lenses. Messrs. Beck also announce a new series of Petzval portrait lenses adjustable for brilliant definition or diffusion.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
29.....	Cardiff Photographic Society ..	"Development." Mr. R. C. Harris.
29.....	Southampton Camera Club	Visit to London Exhibitions and attend Special Meeting of Affiliated Members at the "Royal." (Particulars from Hon. Sec.)
29.....	Wimbledon and Dis. Cam. Clul	Reception at R.P.S. Exhibition, New Gallery, Regent Street, W.
29.....	Bowes Park and Dis. Ph. Soc...	Reception at the R.P.S. Exhibition, New Gallery, Regent Street, W.
30.....	R.P.S. Exhibition.....	"An Idyllic Cathedral." Mr. E. W. Harvey Piper.
30.....	Blackburn Camera Club	Special show of Members' Slides.
Oct.		
2.....	South London Photo. Society ..	"Morocco." Mr. J. H. Avery.
2.....	Southampton Camera Club.....	Demonstration by the Rotary Photographic Co.—Bromide and Gaslight Papers and Colour Photographs.
		Competition of Hampstead Heath Outing Prints. Competition of Annual Holiday Prints. Conversation and Reception of Members and Friends, by the President and Vice-Presidents.
2.....	Bowes Park and Dis. Ph. Soc...	"Five Days in the Walloon Country." Mr. J. Wadham Cook.
2.....	R.P.S. Exhibition	Lantern Night. Goetz Lecture.
2.....	Leek and District Photo. Soc...	"What Can be Done with a Hand Camera."
2.....	Cardiff Photographic Society ..	"Printing Processes." Mr. W. A. Meyrick.
2.....	Luton Camera Club	Enlarging by Artificial Light. Organised by Mr. A. Staddon.
3.....	Halifax Camera Club	"More Continent." Mr. J. I. Learoyd.
3.....	Bristol Photographic Club	"Exposure and Development." Mr. Morris B. Fowler.
3.....	Manchester Amat. Photo. Soc	Lantern Slide Testing Night.
4.....	Edinburgh Photo. Society	"Some Essentials to Picture-Making—A Plain Talk." Illustrated. Mr. James Burns.
5.....	London and Prov. Photo. Assn	Last Night for the Submission of Papers read or published July 1, 1904, to June 30, 1905, for the 1904-5 Award.
5.....	Glasgow Eastern Ama. Ph. Assn	Presidential Address and Members' Slides.
5.....	R.P.S. Exhibition	"A Visit to Gibraltar," with Three-Colour Slides, by the Sanger Shepherd Process and with Monochrome Slides, by Miss Acland, F.R.P.S.
5.....	Wimb'edon and Dis. Cam. Club	"Velox" and its New Applications. Demonstrated. J. J. Griffin & Sons, Ltd.

DEMONSTRATIONS WANTED.—Mr. P. H. Hutchinson writes us from 2, Langholm Terrace, Coatham, Redcar:—"May I appeal, through your columns, for offers of demonstrations or papers—trade—to be given to members of the Redcar and Coatham Literary Institute Photographic Society during this coming session—October to April? We have several dates early in the session open at present."

THORNTON HEATH PHOTOGRAPHIC SOCIETY.—The autumn session of this society opens on Tuesday, October 3, when the president, Mr. W. Wood, will deliver an address.

The opening demonstration of the Wandsworth Camera Club will take place on Monday, October 2, at 8.15 p.m., with a demonstration on carbon by the president, Charles Moss.

BELFAST Y.M.C.A. CAMERA CLUB.—The annual meeting of this club was held in the Minor Hall, Y.M.C.A., Wellington Place, on the evening of the 20th inst. The annual report and financial statement were presented. The membership now numbers over one hundred. Mr. Hugh Cochrane, jun., the popular hon. secretary, was presented with a roll-top desk by the members, on his giving up the secretaryship of the club. The election of officers for 1905-06 resulted as follows:—President, Mr. R. G. Moffet; vice-presidents, Dr. Allworthy, Messrs. W. M. Downing, T. H. McMurray, D. W. Elliott, Richard Hamilton, J. J. McAuley, A. R. Hogg, W. McLean, and H. Cochrane, jun.; hon. sec. and treasurer, Mr. D. J. Hogg; hon. assistant sec., Mr. J. Malcolmson; hon. lanternist, Mr. Alf. George; committee, Messrs. Hugh Hill, J. B. Anderson, Hugh Crawford, H. Rew, S. McLaughlin, P. Kilgour, and J. M. Busby.

THE annual meeting of the Hastings and St. Leonards Photographic Society was held last week, and the condition of the society was regarded as satisfactory, the members having been well to the front in exhibitions. Mr. White-Ford was re-elected president. As vice-presidents, the following were elected: Lord Brassey, Mr. F. Freeman-Thomas, M.P., Alderman Stubbs, J.P., Dr. Gray, J.P., Alderman Tuppenney, J.P., and Mr. Harvey Du Cros. Mr. Simpson, previous to the election of the hon. secretary, proposed that the offices of treasurer and secretary be amalgamated. This was agreed to. Mr. Judge then resigned the position as hon. secretary owing to stress of work, and proposed that Mr. Walters be asked to accept the post.

BRECHIN PHOTOGRAPHIC ASSOCIATION.—The annual meeting of this association was held in the clubrooms, St. Mary Street, on Wednesday of last week. The reports of the secretary and treasurer were considered highly satisfactory, the latter showing a good credit balance. Office-bearers for the next year were elected as follows:—President, Mr. W. S. Adamson, Careston Castle; senior vice-president, Mr. R. W. Duke, St. Ninian's; junior vice-president, Mr. D. B. Robertson, Montrose Street; secretary, Mr. J. M. Dunn, Bank Street; treasurer, Mr. D. M. Watt; curator and lanternist, Mr. R. C. Dalgety; portfolio editor, Mr. W. Lamont; council, Messrs. G. A. Moir, W. Lamont, A. Colville, and J. D. Ross.

EDMONTON PHOTOGRAPHIC SOCIETY.—On Wednesday of last week Mr. Ernest Hurman lectured before the members of this society on "Combination Printing."

WIMBLEDON AND DISTRICT CAMERA CLUB.—This club opened its sixth session on Thursday, September 21, at Mr. Johnstone's, 6, The Broadway. A large number of lantern slides from various societies and friends being shown, a collection from the photographic section of the York Philosophical Society having a new feature. The set was divided into sections, each section having an introductory slide. The title of each picture being projected on the screen at the same time as the slide, thereby obviating the difficulty of struggling with a badly written or other copy in a semi-darkened room.

FIXTURE LISTS, &c., RECEIVED.

THE SOUTHAMPTON CAMERA CLUB'S "Members' Year Book" for 1905-6 has been sent us, and again bears witness to the continued vitality of this southern society, and to the unflagging energy of its hon. secretary. The book is similar to last year's production, and again serves as a convenient vehicle for a good batch of local advertisements. The space devoted to exposure notes is confined to three pages, and the value of the book would be considerably enhanced, we think, if these pages were increased. The winter programme includes several notable fixtures, which shows that sound methods of attracting the members to meetings is a prime consideration of the executive.

THE LEEDS PHOTOGRAPHIC SOCIETY'S syllabus includes a list of interesting lectures, commencing October 10 and continuing fortnightly until April 24. We note the names of Messrs. Harold Baker, Harry Wade, Percy Lund, Godfrey Bingley, Page Croft, T. F. Brogden, and C. B. Howdill down for papers. The session should therefore be a successful one.

THE WIMBLEDON AND DISTRICT CAMERA CLUB'S fixture list is also a good one, and programmes for the coming season from the BLACKBURN CAMERA CLUB and the HUDDERSFIELD NATURALIST AND PHOTOGRAPHIC SOCIETY point to considerable activity in these societies.

TO MAKERS OF TELESCOPIC TRIPODS.—A correspondent, Mr. E. J. Lawler, 39, Lime Street, Fenchurch Street, London, E.C., asks to be placed in communication with makers of telescopic tubular camera stands.

Commercial & Legal Intelligence

At a sitting of the Tunbridge Wells Bankruptcy Court, held on Monday last, Frederick Saunders, photographer, of Southborough, attended for examination. The debtor said his liabilities were £130 16s. 11d., and his assets £30 17s. He began business a year ago, when he opened a shop. He borrowed £50, and spent it on the shop, and subsequently became indebted for about £50 more in connection with the business, so that he actually started his business £100 to the bad. He incurred a further liability of about £50 to fit up a studio. At the date of the receiving order his receipts amounted to between £70 and £80, and he had a further £10 from the Mutual Aid Society, in April, in order to meet his rent. The examination was closed.

THE Burglary at Houghtons.—Walter Sochon, of Albion Road, Dalston, was charged, on remand, at the North London Police Court, on Tuesday last, with being concerned in warehouse breaking, and stealing a number of photographic cameras, worth over £50, the property of Messrs. Houghton, Limited, of Tudor Road, Hackney. Evidence was given that the prisoner had pawned one of the cameras, and endeavoured to dispose of another. Mr. Grain, for the defence, pleaded that his client did not know the cameras were stolen when he dealt with them. The real thief was a young man who had been in the employ of the prosecutors, and with whom the prisoner was associated. That man had absconded. The prisoner's relatives having offered to reimburse the loss, he was bound over in his own recognisances of £60, and two sureties in £30 each, the costs being added to the sum of reimbursement.

THE Metotype Company, Limited.—Official notice is given in the daily papers that the creditors of this company are required on or before October 20, 1905, to send their names and addresses, and the particulars of their debts or claims, and the names and addresses of their solicitors (if any) to Charles Acton Dodds, of 5, Copthall Buildings, Copthall Avenue, London, E.C., the Liquidator of the Company.

ENGLISH CELLULOID COMPANY, LIMITED.—The accounts for the thirteen months to December 31 show a loss, after providing for mortgage and debenture interest, of £19,024. The working capital having been exhausted, three schemes have been formulated for providing additional funds. The first scheme suggested is reconstruction, making a further liability upon all Ordinary shares of 5s., and on all Preference shares of 2s. 6d. per share. The second plan is to reduce the capital to £50,000, and then increase it by the creation of pre-Preference shares to the amount of £60,000, paying off the Debentures, and leaving £28,000 available for working capital. The third proposal is to issue £25,000 Seven per Cent. Second Debentures, which have already been created but not issued. The company was established in 1900 with a capital of £150,000.

At the Yarmouth County Court Mr. A. Margand, Seven Sisters Road, London, sued Madame Angless, the conductress of the Ladies' Orchestra on the Britannia Pier, Yarmouth, for £8, the price of a photographic enlargement and frame. The plaintiff executes portraits in crayon, and he alleged that Mr. Gray, the acting manager at the pier, introduced him to Madame Angless, who asked him to make a crayon enlargement of a group of the ladies' band. He told her the price would be £10. In due course he sent the enlargement, which was 40 in. by 60 in., or, in the frame 52 in. by 70 in. She demurred at the frame, and he said she was not compelled to take that. She promised to write him about it, but had not done so. The defendant emphatically denied that she gave plaintiff the order for the work. Such a photograph would be absolutely useless as an advertisement. The judge allowed plaintiff £2 2s. for his work if defendant did not retain the picture. If she retained it without the frame, judgment would be for £5 5s.

CLAIM for Photo Mounts.—At the City of London Police Court, on Thursday of last week, Mr. Francis Kotch, trading as Kotch and Friedlander, 10, Coleman Street, E.C., claimed £6 10s. for photo mounts supplied to the defendant, Mrs. A. J. Daniels, 38, Tachbrook Street, Westminster. The defence was that the 5,000 cards sued for were inferior to the sample, being a six-sheet card instead of an eight-sheet card; and that the defendant could not use them. Plaintiff said that the cards were printed specially for the defendant with her name and address upon them. They were reasonably fit to fulfil the order. The sample was a six-sheet card. The judge suggested that the parties should compromise the matter, but the proposal was rejected. Then it was decided to accept the opinion of an independent photographer, nominated by the Court, both the plaintiff and the defendant having independent witnesses to support their respective cases. The report from the London Stereoscopic Company, Limited, was in favour of the plaintiff, for whom judgment was entered, with costs.

News and Notes.

MYSTERIOUS PHOTOGRAPHS.—A mild sensation, which has travelled as far as Accrington and Manchester, has been caused in the Radcliffe Hall district by the discovery of a woman's figure on a photograph of the interior of the Close Wesleyan Chapel, taken by Mr. Street, Cross Lane. Mr. Street went into the chapel one afternoon with the intention of taking views of the interior. He had a box containing several unexposed plates, and he took two views. The plates were the ordinary "backed" plates, and were given an exposure of five minutes at *f*/22. When he came to develop them, Mr. Street found that on the first one—a view of the altar windows with the tablets underneath—there was the full-length figure of a well-dressed woman alongside the window. The woman, whose features are quite clear, stands as if waiting for someone, and she has her hands clasped in front of her, just as though she were posing. She also wears a blouse, seemingly of some light material. On the second photograph, which includes the organ, the woman's figure is horizontal, about an inch from the top of the plate. The strange part about this, however, is that the lower part of her body is separate from the top, which, except her head, which is not shown, appears next to it. In every other detail the photographs are practically perfect, and excellent examples of interiors. The gold lettering on the woodwork behind the altar is remarkably clear. As showing that the plates had never been exposed, Mr. Street took, with a third plate at 5 o'clock the same afternoon, a photograph of the interior of the parish church, and this is a perfectly clear one and just as ordinary. The exposure was the same, and the plate of the same make. One of the remarkable things about the first photograph is that the decorations on the walls are seen to be above and not under the shadow, or whatever it is, of the woman, and a glass only serves to bring out this fact more acutely. Mr. Street was alone in the chapel, and, prior to taking the photographs, rambled about in order to find the best position. He is absolutely certain that no one was with him. The photographs have come under the minute observation of several experts in the district and in Manchester. They, however, failed to throw any light on the subject. One fantastic solution suggested is that a woman was standing at her house door about the time the photograph was being taken. The sun caught her reflection in a pool of water near, and threw it on the windows of the co-operative society's reading-room, which in their turn cast it through the ordinary windows of the chapel on to the wall inside. (We admire the ingenuity of this

theory.—Eps. B.J.P.) The photograph, it may be added, was taken from a gallery, so that Mr. Street could easily see if any person went in front of him. It may be remarked that Mr. Street has been inundated with orders for the photograph, which is the full-size plate. It is also on some picture postcards, which he had reproduced. He himself—a good man at the art—is totally at a loss to account for the occurrence.

A PHOTOGRAPHIC periodical which is perhaps unknown to the scientific class of our readers, to whom only it appeals, is published under the formidable title of "Zeitschrift für Wissenschaftliche Photographie." It is the successor of the "Archiv für Wissenschaftliche Photographie," and is devoted entirely to the scientific side of photography, and to the allied subjects. The avowed object of the editor, Prof. K. Schaum, of Marburg, is to develop the physico-chemical and mathematical methods of investigation as applied to photo-chemical questions. The "Zeitschrift" has but few subscribers, and we may commend it to those of our readers to whom German is readable. The publisher is J. A. Barth, 17, Roßplatz, Leipzig, but it is doubtless obtainable through the old foreign booksellers in this country.

PRACTICAL Instruction in Photography ("Oliver Goldsmith" Evening Commercial Centre, Peckham Road, S.E.).—The photographic classes are to be continued this year. The results of last year's examination in photography (senior division) of the London Chamber of Commerce show that the only students who gained medals and double distinction in both theory and practice were students of this centre. Mr. Fred. W. Bannister again has charge of the class, which meets on Tuesdays and Fridays at 7.30 to 10 p.m. Lectures are given from 7.30 to 8.45, and 8.45 to 10 is devoted to practical work in the dark-room, etc. The photographic side is completely equipped with all apparatus, and students are allowed free use of apparatus and chemicals. The fee for the whole course from September 29 to June 20, 1906, is 2s. 6d., and this fee also admits the student to any other class held at the centre. Full particulars may be obtained on application to the principal, Mr. A. W. Pinhorn.

THE firm of Gebr. Laiffe, of Regensburg, Germany, notifies us that it has taken into partnership Herr Oscar Wurfischmidt, and will trade in future as Gebr. Laiffe and Co.

A LANCASHIRE and Cheshire union of photographic societies is now in course of formation by W. Tarnsley, hon. secretary of the Everton Camera Club. His address is 22, Chapel Place, Liverpool.

PHOTOGRAPHY AND MURDER.—According to the "Daily Telegraph," a photograph has been published, and is in circulation in Finland, depicting the actual murder of General Bobrikoff, the late Governor of Finland. As the person who took it must have been an accomplice of the murderer, the authorities commissioned M. Kramarenko, the chief of the Viborg gendarmerie, to trace the author of the photograph. Whilst Kramarenko was busy with his investigations, however, he himself was shot.

CLASSES in photography are held as usual at the Goldsmiths' Institute, New Cross. The courses of lectures and demonstrations commenced September 25, and consist of a six-months' course in elementary photography on Friday evenings (fee, 7s. 6d.) and a six-months' course on Wednesday evenings (fee, 12s. 6d.). Reduced fees are charged in each case to students in the practical classes meeting every Monday and Tuesday evening. The teacher is Mr. W. T. Wilkinson, at whose disposal is a well-equipped studio and dark-room. (We say "dark-room," though the prospectus mentions only a "bath-room"). The department is provided with studio, landscape, lantern slide and copying cameras, enlarging lantern, and a powerful electric projection lantern; it also possesses complete outfits for photo-lithographic and collotype work, for platinotype

and carbon printing, and for retouching and other branches of modern photographic practice.

A READY-MADE gum paper, worked out by Mr. A. W. Hills, of Shotts, is to appear on the market in due course. One claim for the paper is uniformity; it is put forward as suitable for professional work. We know Mr. Raupp, of Dresden, employs gum in his business, but hitherto gum, among other distinctions, has enjoyed that of being the most uncommercial process.

ON and after November 1, 1905, the society known heretofore as the Oldham Field Naturalists' and Photographic Society will take the title of the Equitable Photographic Society, Oldham, and be a separate body from the field naturalists, conducting its own meetings and finances.

MESSRS. RAJAR, LTD., ask us to say that their London offices are closed, and that all communications should be addressed to the Rajar Works, Mobberly, Cheshire.

MR. FRED JUDGE writes us that pressure of business has compelled him to resign his post of secretary to the Hastings and St. Leonards Photographic Society. His successor is Mr. H. Walter, Llanstephan, Zeardon Road, Hastings.

COMMENTATORE BONI, the Director of the excavations in the Forum, Rome, has drawn up another appeal on behalf of the museum which he has been arranging for some time past in the old convent of Santa Francesca Romana. Among other matters, Signor Boni wishes the museum to contain a series of photographs and engravings of the chief works of art inspired by Roman history in general and by the events which took place in the Forum in particular. Previous appeals have produced satisfactory results, and many photographs have been sent from different parts of Europe.

THE London and North-Western Railway Company announce that they are prepared to lend lantern slides showing places of interest on their system for the purpose of illustrating lectures, evening entertainments, etc. The slides, which number close upon 400, can be obtained on application to Euston. They show practically every phase of past and present railway working.

Correspondence.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* * We do not undertake responsibility for the opinions expressed by our correspondents

THE FELLOWSHIP OF THE ROYAL PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—Referring to your issue of 22nd inst., "Ex Cathedra" notes re F.R.P.S., in the interests of the younger members of the profession, and of such gentlemen who may be thinking of applying for the fellowship, I must ask you to be good enough to publish this letter. The total number of Fellows, according to list issued early this year, is 236, and the number elected in one year only, viz., 1895, was 144, leaving but 92 Fellows elected during all the other years. In the face of this fact, how did the writer of "Ex Cathedra" notes manage to concoct the fairy tale he did? I would ask him what great important contributions to photographic theory, practice, or invention, etc., have these 144 Fellows, who were elected in the one year, 1895, given to the public.

Further, I would ask him, was it possible the Council and committees performed their duties with considerable strictness, meeting only twice yearly (as per his paragraph), when they elected the 144 Fellows, in one year?

Whatever method the Council at present pursue when electing Fellows, the foregoing fact proves conclusively that the magic letters F.R.P.S. were awarded simply for scratching one another's backs. What makes this fact more noticeable is that the majority of these 144 Fellows only became members in 1894 and 1895.

The reason why such a large number of gentlemen became Members and Fellows in 1894 and 1895 is made apparent by another "Ex Cathedra" note in the same issue, and I much fear that, although the Photographic Society attained the dignity of Royal recognition in 1894, by its conduct in the year 1895, it sacrificed the dignity of its own Fellowship.

In conclusion, I fear the Council have not yet left off

"SCRATCHING."

[Apparently our correspondent ignores the present tense in which our reference to the recommendation of applicants for the Fellowship was couched. We will not bandy words with one who is evidently in complete ignorance of the circumstances under which the Fellowship of the Royal Photographic Society was created. We may point out to him that his "great majority" is actually 42 of the 144. The figures he quotes correctly will be seen to prove the correctness of our comment as to the surveillance exercised in the recommendation of candidates.—Eds., B.J.P.]

RETOUCHING BY NIGHT.

To the Editors.

Gentlemen,—I have noticed that in your last two issues of the JOURNAL my name has been mentioned in connection with an arrangement for retouching by night. Your first correspondent was evidently a customer of mine, and expressed his satisfaction with the method of lighting he purchased from me. Your second correspondent ("Othello") also referred to my name, and stated: "I do not know what the Bruce apparatus is like, but I know that with a white opal globe, 9 in., costing 1s. 3d., and an ordinary double-wick petroleum lamp, I do my retouching as comfortably as by daylight, and in winter seldom use anything else." I take it that "Othello" wishes to save money to the photographic public, for I certainly cannot supply my simple rig for 1s. 3d., but I write to inform those retouchers who use only the oil lamp and opal globe that it is decidedly not the best method known for dark days or for night work. When I commenced as a trade retoucher I used "Othello's" device for a few years, with a strong circular wick lamp and the opal; then the duplex lamp appealed to me for a time—but still my vision suffered. "Othello" smothered his Desdemona—the light of his eyes—and now the Moor of Venice is trying to smother the light of my eyes with your readers—bad luck to him!

I have experimented with and tried everything. Electric light too violent; incandescent gas ditto; and acetylene in the same category. In fact, I have found all these lights bad for the eyesight, even for reading purposes, and have felt their effects when retouching at night. I have found the lamp that I use and sell, soft, powerful, and non-injurious to the sight. The proof of this statement lies in the fact that for over fifteen years I have retouched by this arrangement, often working ten to sixteen hours a day with it in winter, and I can still paint the finest miniature drawings on ivory and without spectacles or magnifying glasses. The opal globe and lamp must be injurious to the vision, for nothing is done to kill the yellow glare of the oil lamp, and that does the damage. "Othello" may find it all-sufficient, but if continued for a lengthy period, and used extensively as I use it, then unless he possesses exceptional vision, his outlook of the world promises to become as dark as his skin.—Yours faithfully,

T. S. BRUCE.

4, Villas-on-the-Heath,

The Vale, Hampstead, N.W.

Answers to Correspondents.

- ***All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.**
- ***Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- ***Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.**
- ***For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED:—

- W. F. R. Mist, 97, Barden Road, Tonbridge, Kent. *Photograph of a Lily. "A Freak of Nature," with eighty-five Blooms. Photograph of a Child and Flowers, entitled "Among the Lilies."*
- W. G. Honey, 102, Patrick Street, Cork. *Three Photographs of Miss Lena Macnaughten.*
- F. W. Berry, 144, Lewisham High Road, New Cross, London, S.E. *Two Photographs of the Rev. C. H. Grundy, Vicar of St. Peter's, Brockley, London.*
- W. E. Welchman, The Studio, Exchange Street, Retford, Notts. *Photograph of the Royal Train Passing through Retford.*
- W. Dunning, Bridge Street, Usk, Mon. *Photograph of T. Rees Standing on Bank of River Usk with Coracle on his Back; and Photograph of the same Person Fishing from Coracle.*
- W. J. Leech, 134, Wellington Road, Dudley, Worcestershire. *Photograph of the Dudley Football Team, Season 1905-6.*
- F. Verrall, 239, London Road, St. Leonards-on-Sea. *Photograph of Basket containing 118 Children's Portraits, entitled "Our Darlings."*
- F. V. A. Lloyd, 15, Lord Street, Liverpool. *Two Photographs of the 8th (Scottish) Volunteer Battalion King's (Liverpool Regiment) in Edinburgh Academy Grounds. One with the Hon. Col. Lord Strathcona at the Head. September 18, 1905.*

DRAWINGS REGISTERED:—

- W. P. Haycroft, "Colgrove," Alumburst Road, Bournemouth. *Drawing (Water-Colour) of Bowling Green at Alum Chine, Bournemouth.*
- J. C. Hunter, 50, South Bridge, Edinburgh. *Drawing of the late General Wauchope.*

Criticism of Retouching.—Readers desiring criticisms of their retouching should send two prints from three negatives, in each case, one before and one after retouching. The prints should be on glossy paper, and the subjects, an aged person, a young man or woman, and a child. It is impossible to give useful criticism upon the evidence of a single print.

A LIQUIDATION QUERY.—I shall be very glad if you will kindly suggest the best course I can take to recover payment (one guinea) from the proprietors of —. On May 15 last they accepted a picture of the horse Ambition, winner of the Jubilee Stakes, and used it in front full-page picture. I have received no response to several applications for payment, and am now in receipt of letter, copy of which I enclose. Since this transaction the property has been amalgamated with another paper. The point is this: Are not the present proprietors responsible for the liabilities of the property they have taken over, and can I not recover from them now? If this is possible, will you kindly suggest the best course I can take?—F. MILLS.

It appears that you supplied the picture to the Company that is now in liquidation, and unless the new Company took over its liabilities you have no claim on that. You will have to stand in with the other creditors of the Company you did the work for.

A. PIKE.—You might get a berth as general hand in dark-room and printing-room. You should study the advertisements of "Situations Vacant."

MOTOR-CAR PHOTOGRAPHS.—1. Do you think the picture enclosed herewith, showing the dust raised by a motor-car driven at a

great speed, to be a genuine photograph? If not, in what way could it be faked. 2. An observer of a car going at, say, sixty miles per hour, could not distinguish one spoke from another in the wheels, whether they were wire or artillery; but could a photograph taken at right angles show the spokes as stationary, or nearly so? If so, what makes of lenses and focal-plane shutters will accomplish this?—DOUBTFUL.

1. We should say it may be genuine, but it would be an easy matter to exaggerate the dust effect by working on the negative. 2. Beyond the power of the focal-plane shutter, in our opinion. We cannot recall such freedom from blurr even in negatives taken half broadside on to the car, where the conditions are less stringent.

COPYRIGHT.—I should be greatly obliged if you would answer me the following. I have about 100 postcard negatives. I should like to copyright them. Should I have to copyright each separately, or could I copyright all together? Would it come cheaper?—POSTCARD.

Each must be registered separately.

OPERATING AND RETOUCHING (reply to A. H. Pain).—1. It is impossible for us to state the class certificate the P.P.A. will award you. You should have sent your inquiry direct to them for this information. 2. We have several times replied to correspondents that we prefer not to state the probable salary value of assistants, as it might lead to a fixed scale with employers; and, as we have often quoted very low wages to indifferent workers who have sent specimens to us, it would be unfair to those who deserve more. Correspondents must ascertain for themselves their commercial value through the usual channels—advertising and replying to the "Situations Vacant" columns of the JOURNAL.

OBERNETTER'S CHLORIDE-ETCHING PROCESS.—The above process is described in Story's "Photography" as follows:—"A positive is produced on a film of gelatino-bromide of silver very rich in the silver salt. The silver of the developed and fixed image is converted into chloride of silver by the action of a mixture of perchloride of iron and chromic acid. The film is then wetted and brought into contact with the surface of a copper-plate, which it etches, the chlorine leaving the chloride of silver to combine with the copper, forming chloride of copper, which is soluble in water." The above would seem to be an ideal process for amateurs. Is further information accessible in any manual or year book? A very fine specimen was exhibited at the Loan Exhibition at South Kensington, 1905: "Flucht vor dem Feind," lent by Major-General Waterhouse, engraved by J. B. Obernetter, Munich, 1889 (No. 36 in catalogue).—C. W. A.

About the best description is in "The Photographic News," 1884, p. 67.

A CAMERA QUERY.—Could you oblige me by giving the address of the makers of the "University" camera?—ALEX. DIACK.

We cannot say. Perhaps the maker can communicate with our querist care of the Editors.

COLLODION FILM ON COPPER.—I enclose copper plate with photograph on it from print, also enclosed. It is done, I think, by the old "wet-plate" process, and often has to be manipulated on the copper, so that the film must be tough, and not peel up when outlined with a graver. Could you give me a formula for a suitable collodion film for this process, and for a black varnish for background? I should be very glad of any suggestions.—A. S.

We will reply to your query under "Photo-Mechanical Notes" next week.

TONING BROMIDES.—Will you please inform us through the B.J.P.

of a formula for toning bromides as per enclosed. We have tried all the book methods, and only succeed in getting a yellowish sepia tone. We require these for local views, which we have done in P.O.P. up to the present, and want to get as like P.O.P. as possible.—TONER.

The following formula was probably used for the specimen you enclose, and will give you the tone you desire:— $\frac{3}{4}$ oz. of hypo is dissolved in 20 oz. of hot water, to which $\frac{3}{4}$ oz. of powdered alum is added. To this is added 1 drachm of a 10 per cent. solution of silver nitrate. The fresh bath is heated two or three times to 120-140 deg. Fahr., allowing it to cool after each application of heat. For use, the toning bath should have a temperature of 100-120 deg. Fahr. Toning occupies from fifteen to twenty minutes. Prints developed with organic developers, such as metol-hydroquinone, show a greater tendency to reddish-brown in toning. Ferrous-oxalate developed prints give the best sepia colours.

TINTING P.O.P., ETC.—1. Will you please tell me through your columns what kind of colours are suitable for tinting P.O.P. prints under celluloid—I have had some done, and the firm say they are not aniline dyes—and where obtainable? 2. Are Brun's glossy transparent colours suitable? 3. How are the colours made to run smoothly in plain background? Is there any medium used? I have tried several, but cannot get them to run smoothly. 4. Can an electric arc lamp be bought for about £5, if so, where, suitable to take a cabinet full length or a bust? 5. Could any electrical engineer fit it? 6. What distance should lamp be from sitter, standing, and same for bust?—O. B.

1. You will find several suitable colours advertised in our pages. 2. Yes. 3. A little diluted oxgall can be used as a medium, or the print can be prepared by brushing over with:—Purified oxgall paste, 60 grains; distilled water, 16 oz.; rectified spirit, 4 oz. When dry, the surface will take both oil, water, or aniline colours. 4. Write Penrose and Co., 109, Farringdon Road, E.C., or the Westminster Engineering Co., Willesden Green, N.W. 5. Yes. 6. From 8 to 10 ft. away, and about 8 to 10 ft. from the floor. A few trials will soon show the correct distance for most effective lighting.

PALAMED.—Messrs. Ross, Limited, 111, New Bond Street, or Watson's, of Holborn, make cameras that would suit your purpose, but we do not recommend extreme lightness if telephotography is the object, as rigidity is always sacrificed at the expense of weight. The firms mentioned would undertake the work.

FLASH.—The apparatus you specify will probably give as good a result as you can desire with the subject mentioned. It is exceedingly simple to use, and will light any area.

A MASS OF ILLS.—My son has been doing carbon, platinum, C.C., bromides and silver printing, and developing for about two years, and his hands have suffered severely, they being covered with sore cracks of a very watery nature, and the roots of his nails have shrunk back very much, and his nails are also disfigured, and his eyes have also suffered. He was away from business for about two months, and during that time his hands became quite well. Now he has again started on the same processes, and they are becoming just as bad as ever. I should very much like to know what you would recommend to relieve him of this complaint. Any information would be greatly appreciated by your humble servant.—WYKHAMIST.

Probably the bichromate bath is the cause of the skin affections, or possibly your son's hands are sensitive to metol. If you turn to our issue of May 19 you will find the best treatment in the case of bichromate, but in many cases discontinu-

ance of the employment of the bichromate is the only remedy. In regard to the other possible cause, see the recent correspondence in these columns and the article in our issue of June 30.

PRESS PHOTOGRAPHS.—When sending photographs to the illustrators for publication, what is the best paper to use, what developing is best, and should the prints be glazed.—WYKHAMIST.

The best of all prints is a good albumen, next glossy P.O.P. and then glossy bromide. One or two papers are known to prefer fine matt prints. The glossy prints should be glazed by stripping from glass or ferrotype. You might evidence study with profit an article on "Press Photography" in our current "Year Book of Photography."

METOL DEVELOPER.—May metol-Hauff as a developer for plates be used over and over again until exhausted, and be poured into a spare bottle between using, or when mixed with the carb. potass. does it lose its strength? Also, may the bromide be omitted for under-exposure?—S. E.

The developer made up according to Hauff's formula may be used over and over again until exhausted or discoloured. If the bottle containing the used developer is kept filled up to the top, and is well corked, the solution will keep clear for a long time. Repeated use will make it slower in action. The bromide may be omitted for under-exposure, but with some plates chemical fog will result if development is prolonged.

FROME MECHANICS' INSTITUTE Photographic Society's fourth exhibition will be held on November 1, 2, 3, and 4. The judges will be Messrs. C. B. Keene, and F. M. Sutcliffe. There are six open classes, and bronze and silver medals are placed at the disposal of the judges in each. Exhibits will, if desired, be forwarded carriage paid to the Southampton exhibition. Entry forms and particulars may be obtained from W. L. Watson, Cheap Street, Frome.

ANOTHER noteworthy specimen of up-to-date literature from the publicity department of Carl Hentschel appeared on Monday last at the Palace Theatre on the occasion of the production of Mr. G. R. Sims' "Review." It takes the form of a four-sheet newspaper, entitled the "Palace Review," and a copy is presented to every purchaser of a ticket for the Palace Theatre. The whole production is in a witty, chaffing vein, and inconsequent irresponsibility exudes from every paragraph. It is stated to be priceless, which is true, and the Earl of FitzRadium is the proprietor. Subjects ranging from "What a man from Mars thinks of London" to "Are husbands worth having?" are dealt with in the breezy fashion we have been led to expect in these spasmodic literary efforts of the firm of Hentschel, which are all the more welcome on account of their unexpectedness.

NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

EDITED BY GEORGE E. BROWN, F.I.C.

THE forty-fifth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,612 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1906 will also consist of 25,000 copies.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1906 will be modified to make it more than ever the book of universal photographic reference. As in the past, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1906 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded, and wherever practicable new features of an informative nature will be added.

. IMPORTANT NOTICE.—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1st, so as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

EX CATHEDRA.

A Blank "Week in History."

The weekly dose of history which we have regularly administered to our readers during the present year is missing from this issue; but from no fault of ours or our contributor. We saw this historical Sahara of the irrevocable past when the items were planned for Friday morning resuscitation in December last, and no explorations of our friend "Historicus" have been sufficient to bring to light events or innovations deserving of a place in our chronicles of the making of photography. We have reason to believe, however, that October 6 to 12 is the only period of seven days which can be charged with photographic sterility. The series of notes will be continued in unbroken succession to the end of the year.

* * *

The Photograph in Illustration.

Photography as the destroyer of literary taste is the melancholy note sounded in a valedictory paragraph in the last number of "Longman's Magazine." "The reproduction of drawings and photographs (explains the editor in announcing the suspension of publication) has called into existence a number of magazines and papers depending largely upon their illustrations. Competition for the patronage of the sixpenny public has become very severe, and the mere endeavour to keep up a high literary standard is nowadays not sufficient." True enough, the process block has its patrons, the hurried person and the semi-educated, who read their news in pictures, reverting, in so doing, to the method of communicating ideas used by their remote ancestors. Yet we should have thought that the half-tone illustrations of popular journalism were liked by a newly-discovered set of people, vast in number perhaps, but not drawn from the readers of real literature such as "Longman's" throughout its history has consistently offered. And we cannot share a view which has been expressed that the half-tone, by its very universality, is doomed to extinction. The public shows no signs of being sickened of it; indeed, it seems about to dominate the daily Press, to make room, perhaps, for a three-colour form of it in the weeklies and monthlies.

* * *

Second-Hand Apparatus.

Buyers and sellers of second-hand apparatus are nearly always active, if one may judge from the advertisements in the journals every week. Some apparatus is excellent and good value for the money asked, and some just the reverse, and therefore the purchasers should be on the alert in making a selection. If he is not a judge of what is really good, and what is not, he will do well to invoke

the help of a friend in the inspection of his proposed purchase. In the advertisements of second-hand apparatus for sale, it is very usual to see the cost or maker's list price quoted as well as that asked by the seller. If the latter be a great reduction on the former it must not be taken for granted that the article is really the bargain it seems. Take, for example, cameras. During the past decade or two second and third-class makers have been putting cameras on the market at cutting prices, and when they are new there is no question that, as a rule, they are extremely good value for the money, yet it must not be expected that they have the durability of the more costly instruments, or will stand the same wear and tear. This applies more particularly to the lighter and more portable than it does to the heavier and more substantial patterns. One of the former, after a year's not over careful usage, may be practically a worn-out instrument, while one of the latter class, after several years' use in the hands of a careful worker, will be, for all practical purposes, nearly as good as new. In the cheaper forms of cameras of the light and portable type the wood is not usually too well seasoned, or the bellows of the best material; consequently the apparatus quickly deteriorates in use, the joints give, metal work gets rickety, and the slides let in light. Such a camera is dear at any price to the novice commencing photography, as it is likely to land him in no end of trouble. On the other hand, a camera by a high-class maker, after several years' service, may be a bargain at no very great reduction on its original cost.

Cheap Hand Cameras. What has just been said is intended to apply more particularly to stand cameras. When we come to hand cameras, more especially those with intricate and complicated changing arrangements, great care should be taken before purchasing, as the parts, even with careful use, are liable to get out of order after a time, notwithstanding that a good price was paid in the first instance. If this be the case with good class hand cameras, what can be said of those of the cheap kinds, that is of the fifteen shilling or guinea type, when they get into the second-hand market? Often when they are advertised at a few shillings they are really not worth anything for actual use—they are worn out. One general conclusion to be borne in mind by the purchaser of a second-hand camera is that the genuine bargain is most likely to be found among apparatus of the highest class. Manufacturers are now able to produce such excellent instruments at a "popular" price that there is often little to be gained by purchasing second-hand. At the same time an open mind is the best attitude to take in making a purchase of any kind. Actual inspection of the apparatus, to our thinking, should always be made before a transaction, and will usually repay the expense incurred by preventing, oftentimes, what would be a disappointing purchase.

New and Old Lenses. A few words with regard to second-hand lenses may not be out of place. Some persons seem to be under the impression that lenses do not deteriorate by use—a mistaken view, of course. They may deteriorate greatly in the hands of careless users. The high polish given by the makers may become destroyed owing to the lenses having been constantly wiped with a dusty cloth such as the focussing cloth. As a consequence, they do not yield so brilliant an image as when new. The instrument, also, may have had a fall at one time or other, and, although none of the glasses may have been broken, one or other of the elements may have become so jammed in its cell as to alter its figure and centreing, and mate-

rially impair its quality. We recently saw an expensive portrait lens, by one of the best makers, which had been accidentally dropped, but the glasses themselves were not damaged; yet the instrument would no longer produce a sharp picture. On looking through the lens at a gas flame we at once saw that the glasses had become decentered. The instrument had to be returned to the maker to be set right. When purchasing a lens, bearing the maker's name, it should always be submitted to him, and he will always examine it for verification as to its being of his manufacture. Dealers of repute in second-hand apparatus can usually be relied upon in the purchase of second-hand lenses, etc., as the apparatus is usually carefully overhauled before it is put into stock. It is more particularly to the class of goods frequently described as great bargains that our remarks are intended to apply. Although we do not deny the article is worth the money charged for it, we would disabuse the inexperienced purchaser of the idea that the very highest class of goods can be picked up for a song. The preventative of disappointment, however, lies with the purchaser, who should take steps to satisfy himself by actual examination that the instrument answers his own requirements.

Autumn Photography. Summer being past, we have, according to many of our leading landscape photographers, the very best season of the whole year for outdoor photography. In summer sunlight the cast shadows are short and very strong, and a comparatively long exposure has to be given in order to obtain full detail in them. In the autumn they are long and much softer, and hence there is little difficulty in getting full detail, however strong the light may be. The late Mr. Vernon Heath who was one of our finest landscape photographers, did the greater part of his best work during the autumn months, as he considered this was the most suitable time of the year to get the most artistic results. In the country the foliage has not changed much, but in the course of the next few weeks there will be a material difference, and the outdoor worker should be prepared for it, and take full advantage of his opportunities. There is no more glorious sight than a fine landscape in the autumn, with the sun shining on the brilliant tints of the foliage. Unfortunately photography is unable to depict the colours in all their gorgeous hues. Orthochromatic photography, of course, is a great advantage in reproducing the tints in their true relation to colour, though your photographer of the old school will aver that with a full exposure there is little or no advantage to be gained by its employment. The only way by which photography can render these beautiful effects with approach to reality is by the three-colour method, and the opportunities of the next few weeks should not be neglected by workers of that process. At present we have several methods for obtaining prints in natural colours that have really passed the experimental stage, though yet little practised by the general run of landscape workers. Perhaps the most satisfactory process for this purpose, and on the whole the most easy to work, is the carbon process, in which the three-colour tissues are on thin celluloid supports. One other thing must be mentioned in connection with autumn photography. Although the light may be bright, there is not the same actinic quality in it that there was a month or two back. Allowance must be made for that by novices; but at the same time it should be borne in mind that as the shadows are softer than they were in summer they will not require so long an exposure, proportionately, for good tone-rendering, as when the sun was nearer its zenith.

Mysterious Photographs. In our last issue is a paragraph relating to an alleged mysterious photograph taken of the interior of a Wesleyan chapel, in which appears the figure of a woman who was not in the building when the picture was being taken. It is said that this photograph is creating quite a sensation in the district, that the photographer is inundated with orders for it in its original size, that it obtains brief fame as the inevitable picture postcard. The incident suggests a business hint which may be useful to some. It is not at all difficult for anyone to produce mysterious photographs of this sort in many different ways, and under what are called "test conditions," as in the case of alleged spirit photographs. If these get well noticed in the local papers, and made a sensational matter of, there will soon be a good demand for the photographs, more especially if they are issued as postcards. There would, no doubt, be a good sale for photographs of the local electric car with, say, the blind man of local fame as the driver, the thing being seriously boomed as a "mysterious picture." A certain section of the public seem to be fond of the mysterious, and there is no reason why they should not be catered for. We are not suggesting that the chapel interior is of the "freak" character, but photographs of this description will often command a ready sale if cleverly done.

Classes in Photography. The trade classes at the Polytechnic School of Photography, Regent Street, W., commence on Tuesday, October 17. On that evening an introductory lecture will be given by Mr. Howard Farmer, entitled, "Dots, or Coming Events Cast Their Shadows Before." The Polytechnic and similar classes afford apprentices and assistants in photographic establishments in London and the suburbs an excellent opportunity of extending their knowledge and usefulness, and consequently increasing their value to employers. Many of the best appointments in photography open to competition during the last few years have been obtained by students of the Polytechnic; while the fact that out of ten photographic schools in the London district, in eight cases the head instructors were trained at the Polytechnic, may be cited as indicating the character of the instruction. At the examination held last May by the City and Guilds of London Institute, the whole of the medals for photography went to the students of the Polytechnic. Although, as at most of the photographic schools negative making and printing, as well as photo-engraving, processes are taught, it is only at the Polytechnic School of Photography that there is a regular course for professionals engaged in portraiture. Classes in practical operating are taken on Tuesday and Wednesday evenings, and special arrangements are made for students that do their practical work either early or late in the evening as may be most convenient to themselves.

* * *

Two Notable Fixtures at the R.P.S. An ordinary meeting of the Royal Photographic Society will be held, at the New Gallery, Regent Street, on Tuesday next, October 10, when the president, Major General Waterhouse, will deliver his address on "By-Paths of Photography," and will also present the medals to successful exhibitors in the technical section of the exhibition. On October 24, also at the New Gallery, the eighth Traill Taylor memorial lecture will be delivered by Mr. Chapman Jones, F.C.S., F.I.C., who will take as his subject "Photography in the Service of Science."

The "Affiliation" Night.

The meeting on Friday last of the members and delegates from the societies affiliated to the Royal Photographic Society proved conclusively the popularity with which this function is regarded. A queue of goodly proportions spread down Regent Street from the doors of the New Gallery ere seven o'clock had struck, and the flourish of red books in the face of the janitor who effected the process of admission must have brought a glow of satisfaction to the hearts of those responsible for the organisation. The Chairman of the Affiliation (Mr. C. H. Oakden) received the guests, and during the evening gave an address telling those assembled the progress of the past year and the prospects for the future. An exhibition of the slides entered in the technical section of the exhibition, and also the 1905 Affiliation Prize slides were displayed to a critical audience. Mr. Oakden's address is given elsewhere, and his appeal for suggestions from the affiliated societies should not go unheard. The scope and usefulness of the affiliation has no doubt received considerable attention at one time or another from various societies. If they have any advice to give or hints that may be acted upon for the improvement of the organisation they should not hesitate to send along their suggestion to either Mr. Oakden or the Secretary, at 66, Russell Square, London, W.C.

ARTIFICIAL LIGHT AND THE MERCURY VAPOUR LAMP.

THE utility of daylight in comparison with the various artificial illuminants at the disposal of the photographer has frequently formed the subject of debate amongst those directly interested in the management of a studio. Separated from the commercial element the question need not involve a protracted discussion. Nobody, we suppose, will be inclined to question the claim of daylight to be the best of all illuminants, if the photographer is under no particular restrictions in regard to it. If he can draw it from where he wishes, if he can employ it when he chooses, and if he has the opportunity to spend as long as he likes in applying it to his purpose, then there is no competitor to be named in the same category with the illuminant which is the free inheritance of all. But the question of the precise position of the solar gratuity in a commercial relation with other lights cannot be settled off-hand. And it is a question which offers itself for discussion about the present time of year, when the inevitable laws of nature reduce the hours of effective daylight to a comparatively short period before and after noon. Not infrequently the verdict is against the first proposition of the artificial light—namely, that its primary cost and the cost of running it will be returned to the photographer in the increased volume of business. That, of course, is only one of the arguments in favour of a light which must be bought and paid for. A second is a very commercial one indeed. It is the fixity and uniformity of the studio illumination. Instead of the ever variable power and direction of the daylight, there is a light which in these two respects is reasonably constant, though admitting of variation at will within even wider limits than daylight. We say that is a very commercial asset of the system, because it opens the door to the assistant who, with scarcely any experience, may be entrusted with the duties of an operator after having been drilled in the use of a certain fixed arrangement of lighting. Not that artificial light does not offer a great field for the practised operator, but it permits hard and fast conditions under which a responsible person has far less exacting demands made upon him. Such fixity of conditions, carried to an extreme, re-

duces the operator to an automaton, and it is in this respect that artificial light can be of no lasting benefit to professional photography, though it may fill some people's pockets for a few years. In a third respect an artificial illuminant may exert a revolutionary effect on a photographer's business. An illuminant other than daylight empowers you to put your studio where you like, to bring it down from the sixth floor to the street level, where the great public is. The possibility of making such a change may mean everything in some businesses, or it may not be worth the price of a week's gas bill in another. In balancing the probable advantages against the drawbacks of the artificial system, there are chiefly to be considered the power of the light, the quality of the result, and the costs of the installation and maintenance. With a knowledge of the various lights which have been and are at disposal, it cannot be said that, putting cost on one side, any of them approaches daylight in regard to all the factors which determine practical usefulness. Certain arrangements of incandescent gas have proved themselves excellent for illuminating a comparatively small area, but one objection to them is the great heat produced. Systems of magnesium flashlight, unless of a very elaborate character, are not free from the reproach of admitting the magnesia fume into the studio, and where they have been continuously employed with success it has usually been found that the user has perfected the construction of a combustion chamber, from which the cloud of magnesia or aluminic dust has been drawn by a flue into the outer air. In the electric arc light, it might have been thought, lay the realisation of hopes for a perfect artificial light, and, of course, wide use has been made of this illuminant, and a great deal of very fine portraiture has been done with it. Yet the arc is not a cheap light, and the concentration of the light handicaps it in imitating the soft diffused character of daylight. Its disabilities in this and other respects are by no means insuperable, but the means of remedy reduce the working value of a lamp. Though we cannot expect all the virtues of the lights we have named combined in one illuminant, to the exclusion of their defects, there are reasons for expecting in the newest form of electric lamp—the "mercury vapour"—the embodiment of certain properties of pre-eminent importance in portrait photography. The mercury-vapour lamp was the subject of a series of articles in our pages early in the year, and therefore it is not incumbent on us to enlarge upon its constructional features. It is more to our purpose to draw attention to points recommending or declaiming its adoption. Unlike the arc light, the mercury-vapour lamp distributes its illumination from a considerable area. It is a tube of incandescent light—about a yard in length, as placed on the market—and several of these tubes can be placed in juxtaposition to produce a lighting area of extent comparable with the window space of a studio. In that respect, therefore, the lamp has the advantage of arcs with their small light-sources. In point of convenience and mobility the mercury-vapour lamp assuredly is in the better position, and can be more readily made part of the studio's scheme of decoration. Certainly it need never be the eyesore which the umbrella arc-lamp must almost inevitably be. Yet before anything further is said for or against the mercury lamp, its most characteristic quality, and one which we have heard described as damning it in the estimation of any photographer, ought to be considered. We refer, of course, to the spectral composition of the light, and particularly to its lack of red rays. The lamp emits the highly actinic blue and ultra-violet rays in large proportion, but through its deficiency of red rays, it causes objects exposed to it to assume the most unnatural

appearance. The skin appears a livid greenish colour, and though the sitter may not see himself or herself, the first glance at the hand will provoke an exclamation of surprise. From this cause alone, we have been told, the mercury lamp is debarred entrance to a studio. Fortunately, however, it is not difficult to find a remedy. Although the red rays are not in the light they can be evolved separately, and one or two red lamps, or simply a few ordinary incandescent electric lamps will supply the deficient light and preserve the natural colours of surrounding objects. A neater method still of introducing the missing red constituent into the light has been advocated by the makers of the Cooper-Hewitt lamp in America, and consists in screening the tube with thin fabric, impregnated with a pinkish fluorescent dye. The dye alters the wave length of the rays, and thus corrects the illumination of the lamp.

As regards power, the appearance of the light is deceptive. It is not a dazzling or glaring light, inasmuch that no discomfort is experienced in turning the eyes directly upon it. But photographically the light is intensely active. Figures for candle-power based on visual observations underrate its actual efficiency. Practical tests which have come under notice have proved to us the remarkable results obtained with a light which to the eye was not at all a strong light. We have before us a set of four negatives made with two Cooper-Hewitt tubes, employed to give several different lighting effects. The light was screened with muslin, the lens was worked at $f/9$, and the plate was a rapid one, but not of extreme rapidity. Yet the exposures did not run to more than 1 to 2 seconds, and the results, though not all examples of good lighting, are remarkable considering the smallness of the installation. The regular skylight outfit of the Cooper-Hewitt Company comprises five lamps, and though we have not witnessed its performance under test conditions, we can readily entertain the claims made on its behalf.

One other point before concluding our present consideration of the mercury lamp. The cost of current for lamps: on the new system works out at a very low figure. It has been found that one-third of a Board of Trade unit is used by each lamp per hour, a consumption which means 2d. per hour at 6d. per unit, or the battery of five lamps in the "skylight" outfit will cost 10d. per hour. Arc light for equal illumination (visual) can hardly be worked at this figure, and in addition to the difference, the actinic superiority of the vapour lamp must be reckoned. The economy of the lamp is thus not the least remarkable of its features, and one to which in a great measure its favourable reception has been due. Hence, on both technical and commercial grounds, there seems good reason to advise photographers contemplating artificial light in the studio to investigate for themselves the claims made on behalf of the mercury lamp.

THE Secretary of the Photographic Section, Burton-on-Trent Archaeological Society, informs us that the Burton-on-Trent Photographic Society (Y.M.C.A.) has now been merged into his Society. As members of both Societies held their meetings in the same building, it was thought advisable that all interested in photography should meet together. The business meeting of the Photographic Section of the Archaeological Society was held last week at the Society's room in Friar's Walk. W. Howarth was elected chairman, and T. J. Pullin vice-chairman. A. R. Wheatley was elected secretary. H. H. Port and G. Moore, as members of the former clubs, were appointed to act on the committee. The winter programme was arranged, and it was decided to commence a circulating folio. It was agreed to hold bi-monthly competitions. The Secretary's address is 22, High Street, Burton-on-Trent.

SOME OPTICAL FALLACIES WITH REGARD TO THE LANTERN.

ONE of the most remarkable fallacies that we meet with is the idea that the condenser must form an image of the light source at or near the node of the projecting lens if the disc on the screen is to be evenly illuminated. This may be justly styled a remarkable fallacy, considering that a glance at a properly adjusted lantern in working order will usually show that an image of the light source is actually formed some little way in front of the projecting lens, while if the projector be removed, the image will almost invariably be found a considerable distance in front of the position of the projector. The actual position of the image varies considerably with the quality of the optical system and the distance of the lantern screen, but in a large number of cases the facts referred to above are quite obvious.

How the nodal theory originated it is impossible to say, but it is evident that it has been perpetuated by various "authorities" blindly quoting from one another, without troubling to make independent investigation.

Spherical Aberration.

Every lanternist is familiar with the effects of a wrong adjustment of the light. He knows that a dark patch in the centre of the disc denotes that the light is too far back, and that a falling off in the illumination towards the margin of the disc (with, perhaps, the appearance of a dark ring within the disc) shows that the light is too near the condenser. But it is open to doubt whether many lanternists have ever considered the true cause of these appearances, or realised that they are only characteristic effects of spherical aberration.

The dark central spot, which shows that the light is too far back, is nothing but the dark spot characteristic of over-corrected or negative spherical aberration. The marginal falling off of the light on the disc, which indicates that the light source is too far forward, is nothing but the characteristic appearance of under-corrected or positive spherical aberration. Also, the dark ring, which appears when the light is much too near the condenser, is only the characteristic effect of an annular obstruction intercepting the caustic surface which always bounds a spherically aberrated light pencil; the obstruction being the mounting of the projecting lens in the particular case of the lantern.

When the illumination of the disc is uneven, the characteristic effects of spherical aberration can invariably be detected, and the true condition governing the attainment of even illumination is undoubtedly the compensation by the projecting lens of the spherical aberration due to the condenser. This fact has probably escaped notice, owing to the peculiar nature of the conditions, which are not the same as those prevailing in the case of an ordinary photographic objective. The large light pencil or beam projected by the optical system of the lantern has not to be "corrected" for its focus, but for a distant plane well beyond the focus; and the compensating lens is not a negative, but a positive. Further, the amount of spherical aberration to be corrected varies enormously with very slight movements of the light source, one adjustment giving, perhaps, only a few inches of longitudinal aberration that is easily over-corrected, while another adjustment, differing from the first by only a fraction of an inch, may give many feet of longitudinal aberration that is hardly capable of correction.

When the light is too far back the conditions are equivalent to too great a separation of the lenses of the complete optical system (i.e., the condenser and the projector). This favours over-correction, while the positive aberration due to the con-

denser is so greatly diminished by drawing the light back that it is very easily over-corrected. If the light is too near the condenser the lenses are, in effect, too close together to permit full compensation, while at the same time the aberration of the condenser is excessive in quantity. When the light is very near the condenser the light beam contains convergent, parallel, and divergent rays, which complex state of things cannot be compensated by a second lens.

Size of Objective.

Doubts of the truth of the theory that the projector should be at the apex of the cone of rays emitted by the condenser have led to the suggestion that even illumination is secured when the cone of light just fills the back lens of the projector. This condition has, however, little more to do with the attainment of even illumination than the fallacious nodal theory. It is essential that the projector should transmit all the light received from the condenser, otherwise light is cut off, and it is impossible to make a proper adjustment, but it is not by any means necessary that the cone of light should fill the projector, and in practice it very often does not do so. It will usually be found that the cone only fills the back lens of the projector when a small disc is being projected on a very near screen. If the cone exactly fitted the lens with a distant screen, then the lens would be of insufficient diameter to transmit the whole cone with a near screen, for with the latter the light has to be brought nearer the condenser, and the spherical aberration is increased and the cone widened. Such condition would necessitate the use, either of a longer focus condenser with less aberration, or of a projecting lens of larger diameter.

The Quality of the Condenser.

Though it is certainly necessary that the spherical aberration due to the condenser should be corrected, it is not at all certain that a perfect condenser free from aberration would have any material advantages. To produce a perfectly even disc, without any aid from the projector, the condenser would have to be, not only free from all aberration, but also so designed as to illuminate the slide or negative with perfect uniformity. If this latter condition were neglected the illumination of the slide would only be equivalent to that of a plane surface lighted from one small point of light. The illumination would fall off towards the margins, and this effect would be repeated on the screen, in the absence of any corrective action on the part of the projector. We should then either have to obtain a condenser of an almost impossible degree of perfection, or rely to a certain extent on the projector. Even if we did obtain the perfect condenser the whole optical system would only work perfectly and in accord with the nodal theory for one fixed distance of the screen. Any variation of the distance would introduce aberration in the condenser beam, and the projector would then have to step in and correct it. It does not, therefore, appear that the perfect condenser would have any material advantages over the usual imperfect instrument. It rather appears that it is owing to the imperfections of the two elements of the ordinary lantern system that we can attain such satisfactory illumination under a great variety of conditions, provided only that the condenser and projector are well adapted to work together.

The Source of Light.

The ordinary imperfect condenser has the further advantage that it does not require an extremely small source of light. A perfect condenser would not work perfectly in accordance

with theory except with a light source of the smallest possible dimensions, which is not a desirable form of light for ordinary projection purposes with optical or enlarging lanterns. Here we touch on another fallacy with regard to lantern optics. It is very commonly asserted that the smaller the light the better is the result, but, from the point of view of the practical lanternist or enlarger, a very small light is anything but an advantage. What is wanted is a perfect representation on the screen of just the one image plane of the slide or negative, but with a very small source of light we also get shadow images of every speck or imperfection on any of the numerous surfaces

of condenser, plate, or cover glass. In the optical lantern the light passes through eight or ten such surfaces before it reaches the projecting lens, and, while only one of the surfaces is desired to be represented, it is impossible to keep all the rest speckless. With a very small source of light even a small speck may be a complete obstruction and cast a black shadow, but with a larger source no ordinary defect can stop more than an inappreciable amount of light or give a definite shadow. Hence a light source of disc form and of moderate dimensions is by far the best for practical purposes.

C. WELBORNE PIPER.

PHOTOGRAPHIC SOCIETIES AND EXHIBITIONS.

SOME NOTES ON THEIR PRESENT POSITION AND MANAGEMENT.

V.

The Question of Subscription.

As mentioned in a previous article, the vitality of certain societies and the keenness of their members are often in direct inverse ratio to the amount of the annual subscription. There are exceptions, of course, but it will be found that the most "live" societies in this country have usually a subscription of less than half a guinea. Five shillings appears to be the average if the whole of the British societies are taken together, and if a photographic society can be run without loss at this figure, the members generally appreciate what they get in return for their money far more than with a higher subscription. They, moreover, attend the meetings with regularity and take more interest in the affairs of the society. When founding a new society, this question of subscription should always have very careful attention, and the class of members most likely to be attracted to the club should be the chief consideration in fixing the amount. In any case, an amount just sufficient to cover working expenses with a membership of, say, thirty should be a guide.

Value for Money.

The question thereafter for the executive of the society should be: Are the members getting full value for their money. The attitude and attendance of the members themselves will soon answer this query. With societies that have permanent club rooms and dark rooms to which access can be had at all times, the fact is often overlooked by members that these conveniences themselves are part of the return for their subscription, which is usually higher than that of societies with no permanent homes of their own. The photographic papers, too, which are taken in by every society for the benefit of its members is also a consideration, as the combined annual subscriptions payable for these periodicals considerably exceeds the member's annual subscription. A library of photographic books and certain loan apparatus can also be used as an argument showing that value is being given for the money paid in subscriptions. Unfortunately, however, as every secretary knows too well—no matter what the annual amount may be, this return is not regarded as enough. There must be a good programme of fixtures, or interest flags.

The Fixture List.

An inspection of a number of fixture lists and winter programmes from photographic societies all over the kingdom shows a great sameness and repetition in the items. The evening meetings appear to be mostly filled by "trade demonstrations" and "lantern exhibitions." The societies that show the greatest vitality have in addition lectures and demonstrations by either members or outside workers, and those that are affiliated to the Royal Photographic Society appear to make good use of the lectures provided for them by that body. The Scottish

societies, on the whole, show greater variety, and as the majority of these are affiliated to the Scottish Federation, they take full advantage of the interchange of lectures which is one of the features of the organisation. Certain English co-operative bodies, such as the Yorkshire Union and the Northumberland and Durham Federation, also provide for a liberal interchange of lectures.

"Inside" Talent.

It is, however, in the display of original demonstrations by members that the fixture lists are weak and it is in the cultivation of these lectures by members that the energies of the society should be directed if it is to hold a position in the photographic world and do a certain amount of good for photography generally. Just how to cultivate this "inside talent" is rather a difficult matter to decide, but there is no doubt much can be done by arranging a series of "open nights" during the session, and announcing subjects for discussion. For instance, "Failures with gaslight papers" may be announced as the subject of the evening. Every member who has made prints on gaslight papers will look up all his spoilt prints, and when the evening arrives will not only have examples to show, but will also have something to say as to the probable cause of the failures. In the meantime, however, the secretary has canvassed one or two of the leading workers in the club, and prevailed upon them to undertake the start of the discussion. In this way, with a little careful work, a far more interesting evening will result than if a set lecture on "gaslight papers" has been given by one member alone, or a demonstrator from outside the society. In addition to this, certain workers among the members, who otherwise would probably not have spoken at all during the session, will be drawn into the discussion, and the observant secretary should be on the watch for these modest individuals. They will sometimes betray by their knowledge of a subject in these discussions that they have a good grasp of the subject, and only want a little coaxing to give an original demonstration of their methods. By all means, therefore, encourage the "open" discussion nights, and if meetings are held during the same period of the year as the excursions, the members should have some inducement offered them to produce the results of their photographic prowess at these outings.

Competitions.

Competitions among the members should be fostered on every occasion, and, if necessary, prizes should be offered. These competitions can be monthly, or at any other convenient interval. Either set subjects can be announced and marks given by general vote, for the best show of prints produced from negatives taken on a society excursion, and an award made by an outside independent judge. Possibly the mark system—with some substantial awards in the shape of medals at the end of the year—will work best in practice, as the members then have an objec-

in view, and the interest is kept going during the entire year. In any case the results of these club competitions should be exhibited in the rooms for one or two meetings, and if a competent critic can be persuaded to give his opinion on the prints every month so much the better. A circulating portfolio of members' work should also be a feature of every well-conducted society's programme, but this will be dealt with later.

Demonstrations and Lectures.

Every society programme should be "salted" with a sprinkling of lectures and demonstrations given by experts in the photographic world quite apart from trade demonstration, which are admittedly advertisements for the goods demonstrated. The Council of every society should therefore, at the commencement of the session, when the secretary submits a rough draft of the season's programme, arrange that a certain sum be placed on the side to pay lecturer's expenses. In most cases these do not exceed travelling expenses and hotel bills, although this last item is frequently absent, as a member will be found who will gladly play host to the visitor. Four or five of these "expert"

lectures will not only give general satisfaction to the members, but embolden many of the members to emulate the lecturers.

Visitors' Nights.

"Visitors' nights" should also be encouraged as much as possible. On these occasions a set lantern lecture, often of a general character, rather than of photographic technique, will provide a good excuse for the members to bring their friends and relations to see what can be done at "our society." The result frequently means a substantial increase in the membership. The lantern shows that figure rather too often in the programmes of many societies, consisting principally of a series of views, projected on to the screen, and accompanied with a brief title, are simply a waste of time. They should be replaced by discussion nights or demonstrations, although at the same time, the announcement that certain evenings will be set aside for the lantern, during which members' work will be shown, if they bring their slides, will be of use in helping the competitive spirit mentioned above. Other items in the fixture list will be discussed in the next article. "HON. SEC."

THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THIRD NOTICE.

THE technical section of the exhibition, as regards prints at any rate, does not strike one as being strong, and there is a great similarity to previous years' shows, which possibly is unavoidable. Still, the most striking feature is the absence of photo-mechanical processes, for with the exception of three photogravures by the Rembrandt Intaglio Printing Company, Ltd., there is not a single example, save those included in the loan collection from St. Louis. A possible explanation may be that there has been no startling innovation during the last twelve months, and the general level of photo-mechanical processes is so high that not much would offer itself as suitable for exhibition purposes.

This year, however, the lantern slides included in this section are of very high average merit, and obviously the judges were impressed with this view in that they awarded two medals for slides. We speak in vain for pictorial lantern slides. Presumably none were sent in this year, or those that were fell below the standard of the Selecting Committee. We are not surprised at this, for during the last five or six years there has been a marked falling-off, both in the quantity and quality.

The Structure of Metals.

To the casual visitor, possibly the most prominent feature will be the very large number of photo-micrographs of the structure of various metals and their alloys. Interesting, no doubt, and very instructive to the engineer and metal founder, but presenting a wearisome reiteration of general features, of which one soon tires. Mr. Ed. F. Law shows principally steel structures, whilst included in the St. Louis Loan Collection are two big collections by J. E. Stead, Messrs. Harbord and Campion, the Great Eastern Railway Company, H. C. H. Carpenter, and Dr. Rose, the last named also shows some silver cadmium alloy photomicrographs.

Dr. Vaughan Cornish is again to the fore with some unusual phenomena of waves, and although he only shows five, each is well worth noting, as it represents peculiarities in wave structure which are rarely met with or seldom recognised. Possibly the most striking of these is No. 258, which shows the interference bands formed by a succession of points of intersection between the series of diverging waves originating at the bow of the ship and those originating at the stern. To those not familiar with this exhibitor's previous work in wave studies, the selection 524-532 in the St. Louis Collection is worth noting.

Nature Studies.

Of late years an increasing number of photographers have applied their hobby to the study of Nature, and first and foremost to bird life. W. Farren shows some good prints, possibly the most interesting being No. 298, "Lapwing Studies," three prints showing a bird approaching the nest, gathering the eggs under her breast feathers and then sitting. To the ornithologist, however, no doubt No. 300, "Kentish Plover," will appeal most, as this is an extremely rare bird. Miss Turner, F.L.S., takes one of the coveted medals for No. 323, "Great Crested Grebe," a frame containing four prints, showing the bird on its nest. We must confess that we cannot quite see why these should have been singled out, because they do not strike us as being above the average. Bird studies are also shown by F. Martin Duncan, Oliver G. Pike, Jasper Atkinson, and Douglas English.

Other nature studies are shown by R. A. Malby, whose prints showing natural grafts are very curious, but more interesting still is the pair of photographs by J. B. Hilditch, showing the same tree, one being from a calotype paper negative taken in 1853 with ten minutes' exposure, and the other from a gelatine negative taken this year with 1-5 of a second exposure. C. L. Williams shows two sprays of the small-leaved Virginia creeper, printed by direct contact, without a camera; a method which recalls the old nature prints of sixty years ago, the only advantage of which we imagine to be the fine reproduction of the venation of the leaves. The fish studies, taken from life, by Dr. Ward, are good and W. Farren's prints of the skin moult of the caterpillar of the Privet Hawk moth are also striking.

Radiography and Photomicrography.

Dr. Thurstan Holland's radiographs are certainly some of the finest we have seen, and show well the structure of deep-seated parts. They speak well for the "pressure tube apparatus," designed by him, with which they were taken. The value of radiography is also well proved by Dr. Rodman's exhibit, which shows very clearly the internal structure of shells, thus doing away with the necessity of destroying the shells, which hitherto has been the universal practice.

Mr. Pigg shows photomicrographs of sections of the hairs of mammals, and Mrs. Pigg has some very good studies of the germination of a grass seed.

There are one or two other exhibits, two telephoto studies and some studies of a splash by A. C. Banfield. In this section also is a three-colour print of tulips by the carbon process by W. E. Brewerton, and next to this hangs "A Woman of Connemara," by J. Cruwys Richards, which is, we presume, a study in gum in colours.

The St. Louis Loan Collection.

Here are to be met many old friends, such as Mr. Edgar Senior's photo-micrographs of negative and Lippmann films, and the astronomical and spectroscopic work by the Rev. Father Sidgreaves, of the Solar Physics Observatory at South Kensington. Here, too, is a more extended series of the life history of a splash, a work which was, we believe, first done by Professor Worthington and R. S. Cole some ten years or so ago. Nature studies by R. B. Lodge and Douglas English, and T. E. Freshwater's photo-micrographs will be recognised, and possibly a few may remember 515 and 516, two moonlight views by Sir William Abney, which were ignominiously rejected by a selecting committee many years ago.

A very large series of metal structures is also shown, and some Playertypes. The exhibit by Mr. A. J. Newton of the work done at the London County Council School at Bolt Court, is interesting and, as we have already pointed out, with Major-General Waterhouse's exhibit of old processes, forms the only photo-mechanical work.

Visitors should certainly not miss the three-colour slides by Dr. Norman, nor the studies on the biology of flowers by B. H. Bentley, M.A., F.L.S.; these are, from an educational point of view, extremely valuable. Newton and Company are credited in the catalogue with 200 slides dealing with various subjects, but only a few can be shown in the lantern stand in the North-room.

The Lantern Slides.

We cannot remember two medals having been previously awarded to lantern slides at the R.P.S. show, it must certainly be many years ago, and, if we remember rightly, not then for technical slides. One award goes to Dr. Donald H. Hutchison, for a series of the slides of butterflies by the Sanger-Shepherd three-colour process. It is stated in the catalogue that "the scientific interest attaching to these slides is in the accurate reproduction of the colours of the insects, and the usefulness of this method for recording rare varieties." Whether we were unfortunate as regards the light or something else, we do not know, but certainly some of the less rare varieties with which we are tolerably familiar do not seem to us to possess their natural colour there being an irritating preponderance of green in many of them.

Dr. J. W. Ellis, of Liverpool, has long been noted as one of our leading lantern slide workers, and his collection of 60 slides of English and Welsh mediæval baptismal fonts fully maintains his reputation for technical skill, and he deservedly wins the second medal. Specialisation such as this is much more satisfactory from a points of view than the haphazard snapshotting which is so prevalent now, and many a one who is now discontented with his hobby would take it up with renewed vigour and interest if he followed Dr. Ellis' example.

The micro-organisms by Mr. Percy P. Wilding will appeal to the microscopist, and one or two of them are very fine examples of work. Although included in the lantern slide section in the catalogue, the case of three-colour transparencies by Mr. Walter Bourke is in the gallery with the technical prints, and as far as one can judge, the results are good examples of the process, but it is somewhat difficult to see them on account of the top light.

ON MAKING NEGATIVE ENLARGEMENTS.

II.

Control in Making the Positive.

A SIMPLER method of obtaining modifications than subsequent work of any kind is to obtain local reduction or intensification in the exposure of the positive. I mean by this that if, in the original negative, there is a portion which prints too dark, it can be corrected in making the enlarged positive. A piece of paper a little smaller than the enlargement of that part should be cut out and pasted on a large piece of glass. This paper mask may be held in front of the very thin part of the negative during part of the exposure. If there is a part of the original which is much too dense, a hole may be cut in a large piece of black paper the shape of the dense part, but smaller, and the paper held midway between the lens and the plates in the frame. This will hold back all of the rest and force full detail from the refractory portion.

Clouds.

If clouds are wanted and are lacking in the original, they may be "wiped in" on the paper backing in a way to be further described, or else printed in from another negative. To do this latter most successfully, arrange everything for the exposure except adjusting the plate. Fasten a piece of cardboard larger than the plate to be used on the easel, and have its position accurately registered as by thumb-tacks. With the lights turned out and with the projected image on the card, trace carefully the horizon line of the original negative as enlarged, and leaving the registering pins or tacks in place, cut the card in two, following the line. With the two pieces of card used alternately expose the original for the lower part and the cloud negative for the sky. If accurately done there should be no more than a hair-line to be retouched in subsequently. The same method may be used with

one negative where the clouds are very dense, in that way holding back the thin part of the negative more accurately than by ordinary shading or masking. The proper effect will then be obtained on the negative without having to resort to any shading in making good prints from the large negative.

The objection to making changes from the actual atmospheric effect at the time of exposure is that false lighting is likely to be caused rendering the "picture" worse than useless. To the pictorial worker whose first and last aim is a picture, the modifications in negative are perfectly legitimate. In fact, it has become assumed that pictorial photography means photography aided by the mind and hand. The question of honour comes in only when the photographer claims the effect to be untouched—for instance, in a contest in which unretouched work is expected and required.

Preparation for Exposure.

With a positive ready for the contact exposure, examine it carefully to determine the exposure, and to decide upon the effect required in the final negative. The exposure in contact work may be easily learned. There should be a shelf a few feet from the source of light and on a level with it for the centre of the plate. The light must be uniform; a gas-jet always turned on full; a Welsbach, always in good order; or an incandescent electric light. A trial should be made to learn the printing time either with a small plate of the make to be used or with a strip of bromide paper, covering portions and giving timed exposures, as suggested in the last article. The ratios between the paper and the plate here given may then be used to determine the exposure of the plate. If cost is not important it is still better to sacrifice one plate on an experimental exposure in sections.

In loading the printing frame for the exposure, it should be placed slanting on a shelf so that there may be the least possible opportunity for dust on the transparency. Then place, first the transparency and then the new plate in position film to film. For diffusion, use the separators which come in the plate box. A piece of black paper between the plates and the backboard of the printing-frame will obviate any possible halation. Should any part of the positive be too dense, incline the frame with that part toward the light. The negative so made should print perfectly. The time of the first satisfactory print in bright sunlight should be carefully noted and marked in one corner of the negative. All subsequent prints made under the same conditions should be uniform and the wasting of large paper will be unnecessary.

Negative Making by Contact with Bromide Paper.

The method of making negatives for exhibition work by contact, using bromide enlargements, I believe is an original one. At any rate the process is exceedingly interesting and has several advantages: Economy, in the use of but one large plate; certainty, on account of a uniform exposure being given for all negatives; and third, it is a method by which modifications and corrections may be made with greater ease than by using glass positive. In giving a detailed description of the process I would prefer to avoid personal references, but can tell the story more clearly and intelligently if I take one of my negatives and describe the means by which it was made. Let us then take the negative, 18 by 22 inches, of the picture called "Saint Anne's Day," representing the interior of a church in Brittany, with the congregation of women in their white Breton caps. The original film was made with a Kodak. I had held the camera as high as I could reach against the rear wall of the church, gauging the distance at 75 ft., and stopping down about one-half in order to bring into focus far and near points. The shutter was opened and closed with the hanging bulb, the exposure being a little over half a minute. During the time, absolutely necessary on account of the "dim religious light," many of the heads had moved, no one else knowing that a photograph was being taken. There was, therefore, a great deal of blurring in the lower part of the film, and when the negative was magnified the effect was, of course, very bad indeed. The lighting was also very irregular, being in excess in the upper part of the church and on the white caps of the women. The paper used for the enlargement, the same size as that of the plate intended to be made, was thin, smooth bromide, which has a very regular texture and a surface well adapted to the use of the pencil.

Masking.

The whole negative was first exposed for the time required to print the thin portion, then a piece of cardboard was held in front of the thin part as shown on the screen, and moved slowly upward as the lighting in the film gradually increased towards the top. The upper part of the bromide paper was in that way exposed two or three times as long as the central part. Then, with two pieces of cardboard, the whole of the image was covered except where the heavy high-lights of the caps appeared in the lower part of the film. This brought out the detail which otherwise would have been lacking. It will readily be understood that if a bromide enlargement had been made without these precautions the central part of the church would have appeared very black, or else the top would have been white and the caps mere white patches. The print, when developed, proved to have been exposed to represent uniformity of lighting, or as if there had been windows in the lower part of the building instead of at the top alone. After washing, the print was fastened to a flat board by means of thumb-tacks, so that in drying it was stretched flat and smooth. I now use, instead, a strong solution of glycerine, after which prints dry flat when hung up and have no tendency to curl.

Retouching the Positive.

The trouble commenced when it came to removing the many evidences of motion. A very few of the people had not moved, including one old woman who was standing, and these few deserved my benediction. The retouching materials consisted of a number of lead pencils of different grades of hardness. In some parts of the print, hair-lines were sufficient to make the corrections. In others it was necessary not only to use the blackest pencil, but to put on all of the lead that the paper would take. When the print appeared to be finished, it was taken from the board or easel and held up to a window so that it could be examined by means of the daylight passing through. There were still some places where the moving caps had left lighter patches. These places had to be worked up again on the white side of the paper. This was done by holding the print against a large window-pane. There were no insertions in the print, the only modifications being those for the lighting and the correction of the motion, both of which changes would be regarded as legitimate by the most earnest advocate of the doctrine of straight photography.

Making the Negative.

It is necessary in using this method to make sure that the back as well as the face of the print is free from marks or stains, excepting, of course, the retouching marks. Dirt or stain on either side of the paper will cause blemishes in the resultant negative. The materials required in making the negative are: A printing frame the size of the negative and a piece of clear glass to fit the frame. The clear glass is first placed in the frame, then the bromide picture with the white side next to the glass, and then the dry plate, coated side next to the film side of the print. The back is then clamped on the frame ready for the exposure. With a fast plate one does not obtain sufficient density on account of the thin emulsion of the paper, while a process plate would produce rather too harsh an effect. It is best to use but one kind of plate in all work by this method, and to learn the exposure and development of that plate as perfectly as possible.

The Exposure.

To make the exposure, there should be a narrow shelf in the dark room about five feet distant from the white light. A screw-hook may be used to hold the heavy printing frame in place. All bromide prints, correctly exposed and developed, will receive a uniform exposure by this method. It is therefore important to find out precisely what that exposure should be by experimenting with strips of bromide paper. The preference between underexposing and overexposing would be to overexpose slightly in order to avoid the harshness resulting from prolonged development. Such harshness would cause the grain of the paper to show in both the negative and in prints from it. Strange as it may seem, a negative properly exposed and developed gives scarcely any evidence of the texture of the paper unless one prints on a slow gaslight paper, which of course he will not wish to do with work of this character. The plate being a very little overexposed, it should be normally developed so that the image will be nearly darkened out when development is complete. Considerable overexposure will produce flatness, so that the word "slightly" is important. Development should be full, but not forced. The plate should be washed before development and the whole surface lightly rubbed with the hand to remove bubbles, which cause pinholes. The tray containing the plate should be rocked during the development to secure evenness. The result is worth the additional trouble. The negative should be carefully rinsed to avoid stains and then fixed. The best developer appears to me to be metol-hydroquinone.

Enlarging from a Small Contact Positive.

This is the method which is usually employed by the experienced amateur photographers who are willing to take the trouble to make large negatives for their own use. The reference to it can be very

brief, as the process is quite similar to that of enlarging on paper. It is not always the best looking transparency which gives the best negative. A positive made on a slow plate is apt to have more contrast than the original negative, and while such additional contrast may be very pleasing to the eye, too much harshness is apt to result in enlarging it to a negative. The right positive is usually a slightly overexposed one, developed for detail with a rather weak developer, such as diluted metol-hydroquinone. The positive must be made with the greatest care, as the most minute pinholes caused by air-bubbles or gas in old developer will, when magnified, cause the negative to be most unsatisfactory. An excellent way of printing a positive is to use a wax match and hold the small flame a little in front of the too dense parts of the negative.

Secondary Enlargements for Negatives.

The method which is usually employed by professionals in making large negatives is to first make a transparency enlargement of about one-half the diameter of the final negative and then make the final negative by a secondary enlargement from it. The reasons for this are twofold: First, some economy in plates, and second, the professional feels more at home when all of the work is done by enlargement rather than partly by contact; that is, he believes he can judge the exposures better when he sees the image thrown on the enlarging board. This method can be sufficiently learned from that which has been already written, so that no further reference to it is required.

Paper Negatives.

Paper negatives can be classed with "freak" work, suited for certain purposes, but not to be depended upon for all-round use, either by the amateur or the professional. They have the great advantage of economy. The silver emulsion of bromide paper is much thinner than that of plates. As a result, a print from a paper negative is lacking in strength and gives a flat, faded appearance. The amateur who wishes to have a "low-toned" effect may obtain it by using a paper negative. Suppose, however, that the matter of economy is an urgent one, the pictorialist not having the means or perhaps the opportunity of purchasing large plates, it is then a question of ascertaining the method of making the best possible paper negatives, for printing with sufficient contrast on any sun-printing paper. He should give the right exposure to obtain the needed detail, and, by using plenty of developer so as to keep the paper well covered from the air, give as long a development as will be possible without staining or fogging. In other words, he will aim to give the paper negative all of the "body" that can be obtained. He can work up the paper negative when dry by means of the pencil or charcoal, and in that way can frequently secure remarkably good results. A way of making these negatives with full contrast from flat originals is to work for contrast in the contact positive by using a slow plate or by prolonged development, or both. Another plan is to use gaslight paper instead of bromide, giving, with regular Velox paper, an exposure of minutes instead of seconds, as compared with bromide. This paper makes good negatives, although the increased contrast frequently makes the high lights unprintable. When the negative made by any of these processes is ready, the first print should be made in full sunlight and carefully timed. The suggestion has already been made that the time of a correct print in full sunlight should be marked in a corner of the negative with one of the blue marking pencils, so that all future prints may be correctly exposed without spoiling paper.

WALTER ZIMMERMAN.

On October 25 Messrs. Cassell and Co. will issue the first seven-penny part of Sir Benjamin Stone's pictures. The first series to be issued from La Belle Sauvage will deal with British festivals, ceremonies, and customs.

THE AFFILIATION OF PHOTOGRAPHIC SOCIETIES.

MR. C. H. OAKDEN, in welcoming the representatives of the affiliated societies at the New Gallery, Regent Street, on Friday evening, September 29, said:—

"On behalf of the Executive Committee I wish to say that it is their express desire that you should bring forward suggestions for their consideration. Every society, no matter how small, has an equal voice in the management, and any suggestion that is made receives most careful consideration, and if it is found to be valuable it is carried into effect, so that the members individually have practically a joint interest in the affiliation.

The Executive Committee, during the past year, have, owing to the new arrangements made concerning the "Red Book," a larger amount of money at their disposal, and that has enabled them to expend a larger amount for the general benefit. It was found, as the years went on, and the members of the affiliated societies increased, the demand for the "Red Books" became so much greater, and the cost consequently so much more, that very little money was left for other benefits. After a very long and careful consideration and discussion it was decided to make a small charge for the "Red Book," and in that we have included a number of permits. I think I ought to say one word with regard to these permits. They are granted as a matter of courtesy—not as a matter of right—on the part of the persons in charge of, or the owners of, the properties. Therefore you cannot make use of these permits as a matter of right, and seek to enforce the permit against the will of the owners or the persons in charge of the property. Much difficulty has been experienced in obtaining these permits, and it is the misuse by some photographers of the right to photograph that very often creates a large amount of difficulty in including a certain place in the list. To give an instance: During the past year we have been making certain inquiries and extending this list of permits. The result has been that we found in one case a society (I cannot believe that it is an affiliated society) obtains permission to photograph in a public building, and when at work there they abused their privilege and offended the principal person in charge, the man who had practically complete control. The result is we are no longer able to include that building as one which the "Red Book" will enable you to go into and photograph. The terms upon which permission is now granted are of the most onerous character. I therefore ask all members of societies, when making use of these permits, to use them in a proper manner, and not to use them in a manner which this unaffiliated society has done. I am very sorry that such a thing has occurred.

The "Red Book" also includes this year a number of half-price tickets to the Royal Photographic Society's Exhibition, and this has been arranged by the Executive Committee with a view of saving your secretaries trouble.

With regard to the print competition, the Executive are having the prints illustrating lectures passed by the Selection Committee covered with celluloid, and fitted with stiff backs.

Mr. J. McIntosh (the Secretary of the Affiliation) has written a fresh lecture upon "Intensification and Reduction"; Dr. Norman has prepared for us a lecture (illustrated) on the "Three-Colour Process in Photo-Micrography"; Mr. F. Martin Duncan, "Photography of Marine Life"; Mr. E. W. Taylor, "After-Treatment of the Negative"; Mr. F. J. Mortimer has written a lecture on "Marine Photography"; Mr. J. P. W. Goodwin on "Making Enlarged Negatives," illustrated by small negatives and enlarged negatives; Mr. F. C. Tilney on "The Romantic in Landscape"; Mr. H. W. Bennett on "The Selection of a Printing Process"; Mr. E. T. Holding, "Figure Studies"; Mr. J. C. S. Mummery, "Gum-Bichromate"; and Mr. T. Coysh, "Architecture." In addition to

lectures, arrangements are being made to provide a further set of architectural slides, with descriptions by a well-known writer. It is proposed to limit the number of slides sent in for competition at year. At the end of November we are holding a print competition on similar lines to that held in 1904; and in the following month we have a competition of an entirely different character, called a "Lecture Competition." It is open to every member to write a lecture on a photographic subject of general interest and send it in with a chance of winning a plaque and securing payment of five guineas if the lecture is accepted. The idea of this competition is to keep up the number of lectures available for circulation. One other feature that I must call attention to is the steps which we have taken during the past summer to link up to the affiliated societies those who describe themselves as "Down Unders." I refer to the societies on the other side of the world, the societies of Australia, New Zealand, and Tasmania. During the past summer representatives of those societies have visited the rooms of the Royal Photographic Society, and have conferred with the Executive Committee, and arrangements are almost completed by which lectures will be circulated on the other side of the world with equal facilities to which they are circulated in this country. I must say that these gentlemen, when they understood the advantages granted by the Affiliation, were very much surprised, and they stated that the Affiliation had been much misrepresented on the other side of the world. They practically told us that we were providing them with too much for their money. It is, however, the intention of the Executive Committee to provide you with as much as they can by the means at their disposal."

DEATH OF MR. JOHN HOWSON.

It is with very great regret that we have to announce the death of Mr. John Howson, which took place on Tuesday last, October 3, from aneurism of the heart. Mr. Howson had been in failing health for some months, but on his return from the sea quite recently it was seen that the disease would have a fatal termination. Mr. Howson's name was so well known throughout the photographic trade that it is scarcely necessary for us to refer to his connection first and for many years, with the Ilford Company, and subsequently with the Imperial Dry Plate Company. Under his commercial management—which commenced almost with the inception of the present firm of Ilford, Limited—a series of pioneer steps were taken towards the establishment of popular photography, and, as a corollary, the foundation of plate and paper making as an important industry. The introduction of P.O.P. is, perhaps, associated most intimately in the public mind with Mr. Howson's name, for he spared no energy in familiarising British photographers with the paper, which his company was the first to place on the market. But in other directions his labours were freely devoted to the important interests of the Ilford business. For several years he had been associated in the commercial management of the Imperial Dry Plate Company, Ltd., and his demise, in little more than middle life, has evoked sincere expressions of regret from the staffs of both the great establishments with which he was connected. The interment is to take place to-morrow (Saturday) at Kensal Green Cemetery.

ECLIPSE Photographs.—Gradually the results of the different expeditions of "eclipse" observers are filtering in, those from Egypt being especially interesting. Professor Turner, whose duty it was to measure the coronal light, took fourteen photographs; Mr. J. H. Reynolds mounted at Assouan his 120-ft. reflecting telescope, and with its aid took two photographs which should prove the most valuable of all. The American mission used a camera 40 ft. in length, and took eighteen photographs.

FORTHCOMING EXHIBITIONS.

September 21-October 28.—Royal Photographic Society, New Gallery, 121, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

September 15-October 21.—Photographic Salon, 5a, Pall Mall East. Hon. Secretary, Reginald Craigie, Camera Club, Charing Cross Road, W.C.

October 11-13.—Northcote Camera Club. Hon. Secretary, H. Clifford Bennett, 26, Granville Road, Walthamstow.

October 17-18-19.—Isle of Wight Photographic Society. Hon. Sec., V. Howard Burgess, 53, Pyle Street, Newport, I. of W.

October 18-21.—Rotherham Photographic Society. Hon. Secretary, H. C. Hemmingway, Tooker Road, Rotherham.

October 19-21.—Grangemouth Amateur Photographic Association. Hon. Secretary, Robert Marshall, 3, Park Terrace, Grangemouth.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

October 31—November 1.—Cambridge and District Photographic Society. Hon. Secretary, T. J. Sowdon, Sunny Side, Guest Road, Cambridge.

November.—Edinburgh University C.C. Hon. Secretary, Harold C. Simpson, University Union, Edinburgh.

November.—Bristol and Clifton Arts and Crafts Society. Secretary, R. H. Parr, 5, Grove Buildings, Blackboy Hill, Bristol.

November, December, January.—Second American Photographic Salon. H. Snowden Ward, 6, Farringdon Avenue, London, E.C.; Wm. T. Knox, 279, Washington Street, New York City, U.S.A.

November 1-4.—Frome Mechanics' Institute Photographic Society. Hon. Secretary, Wilfred L. Watson, 14, Cheap Street, Frome.

November 1-4.—Hackney Photographic Society. Hon. Secretary, Walter Selfe, 70, Paragon Road, Hackney, N.E.

November 3.—S. Norwood Photographic Society. Hon. Secretary, George R. Beckett, 28, Carmichael Road, S. Norwood.

November 8-15.—Croydon Camera Club. Hon. Sec., W. H. Rogers, 88, Woodville Road, Thornton Heath.

November 14, 15, 16.—Ipswich Camera Club. Hon. Sec., R. H. Sutton, 37, Henley Road, Ipswich.

November 16.—St. Matthew's (Bootle) Camera Club. Hon. Secretary, H. Tempest, 78, Thornton Road, Bootle, Liverpool.

November 16-18.—Burnley Camera Club. Hon. Secretary, F. Pinder, Mechanics' Institute, Burnley.

November 17.—Redhill and District Camera Club. Hon. Secretary, James Paterson, M.A., Whalley, Lynwood Road, Redhill.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

November 21-25.—Sefton Park Photographic Society. H. Cubley, 3, Langdale Road, Sefton Park.

November 23-25.—Isle of Thanet Photographic Society. Hon. Sec., L. G. Hodgson, 58, Queen Street, Ramsgate.

November 25-December 2.—Glasgow Eastern A.P.A. Hon. Secretaries, Thomas B. Kirkhope, 37, Winston Street, Parkhead, Glasgow, and John Brough, 68, Dalmarnock Street, Parkhead, Glasgow.

November 27-30.—Lancaster Photographic Society. Hon. Secretary, R. T. Simpson, 60, North Road, Lancaster.

December.—Muirkirk A.P.A. Hon. Secretary, William Barrowman, Ayr View, Muirkirk.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sarjeant, 55, The Drive, Hove.

December 6-7.—Watford Camera Club. Hon. Secretary, E. H. Jackson, 100, High Street, Watford.

December 12.—The Scottish Photographic Federation Lantern Slide Competition. Entries to Hon. Secretary, John B. MacLachlan, Blairgowrie.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

December-January.—Wishaw Ph. A. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January, 1906.—Shettleston Camera Club. Hon. Secretary, Wm. Kitson, Hawthorne Villa, Shettleston.

January, 1906.—The Dover Institute Photographic Society. Hon. Secretary, H. Plowright, 47, Maison Dieu Road, Dover.

January, 1906.—Brierley Hill Camera Club. Hon. Secretary, J. Thomas, William Street, Brierley Hill.

January 11-13, 1906.—Boston Camera Club. Hon. Secretaries, H. M. Hames and R. W. Halliday, 65, West Street, Boston.

January 13-February 3, 1906.—The Third Scottish National Salon at Dundee. Hon. Secretary, V. C. Baird, Broughty Ferry. Entries close December 30, 1905.

January 25-27, 1906.—South Essex Camera Club. Hon. Secretary, Thomas Michell, 180, Browning Road, Manor Park, E.

January 31, 1906.—Tring Camera Club. Hon. Secretary, J. Owen Raymond, Frogmore Road, Tring.

- February, 1906.—Windsor Camera Club. Hon. Secretary, Thomas J. Cartland, Thames Side, Windsor.
- February, 1906.—Cardiff Windsor A.P.S. Hon. Secretary, W. A. Woodward, 187, Mackintosh Place, Cardiff.
- February-March, 1906.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congreve Street, Birmingham.
- February 3-February 25, 1906.—Marseilles Fourth International Salon. M. Astruc, Sec. Gen., 11, Rue de la Grande-Armée, Marseilles.
- February 6-9, 1906.—Guisbrough Fine Art and Industrial Society. Hon. Secretary, George Page, 34, Westgate, Guisbrough, Yorks.
- February 13-27, 1906.—Greenock C.C. Hon. Secretary, W. D. Boyd, 2, Church Place, Greenock.
- February 20-21, 1906.—Royal Albert Institute, Windsor. J. W. Gooch, Hon. Secretary.
- Feb. 22-24, 1906.—Bowes Park and District. Hon. Sec., H. C. Bird, 91, Whittington Road, Bowes Park, N.
- February 24—March 10, 1906.—Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 5A, N. St. David Street, Edinburgh.
- March, 1906.—Larkhall C.C. Hon. Secretary, Robert Rodger, 26, McNeill Street, Larkhall.
- March, 1906.—Leicester and Leicestershire Photographic Society. Hon. Sec., W. B. Woodland, 18, Beckingham Road, Leicester.
- March, 1906.—Rugby Photographic Society. Hon. Secretary, R. N. Myers, 13, Bridget Street, Rugby.
- March, 1906.—Photographic Society of Ireland. Hon. Secretary, H. V. Yeo, 194, Clonliffe Road, Drumcondra, Dublin.
- March, 1906.—St. Helens Camera Club. Hon. Secretary, John Glover, 14, Ormskirk Street, St. Helens.
- March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.
- March 6-20, 1906.—Glasgow Southern P.A. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.
- March 7-8, 1906.—Doncaster Camera Club. Hon. Secretary, T. Haigh Connor, 39, Market Place, Doncaster.
- March 13-14, 1906.—G.E.R. Mechanics' Institute (Stratford). Hon. Secretary, A. Woolford, 16, Grove Green Road, Leytonstone, E.
- March 14-17, 1906.—Nottingham Camera Club. Hon. Secretary, S. W. Barlow Yines, Market Chambers, South Parade, Nottingham.
- March 19-24, 1906.—Sunderland Photographic Association. Hon. Sec., William E. Kieffer, Stirling Street, Sunderland.
- April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.
- April 1, 1906.—Coatbridge Co.-Op. C.C. Hon. Secretary, James Robb, 6, Windsor Terrace, Blenheim, Coatbridge.
- April 20-21, 1906.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen, Ashcroft, Bushey Hall Road, Watford.
- May, 1906.—Warrington Photographic Society. Hon. Secretary, A. C. Smithson, 13, Chester Road, Warrington.

FORTHCOMING COMPETITIONS.

- October 15.—Lantern Slide Competition, Association Belge de Photographie. Secretary, Palais du Midi, Brussels.
- October 31.—"Zigo." Cash prizes for prints on "Zigo" self-toning paper. Thos. Illingworth and Co., Limited, Willesden Junction, London, N.W.
- November 30.—Royal Photographic Society "Affiliation" Print Competition. Particulars from the Secretary, 66, Russell Square, W.C.
- December 30.—Royal Photographic Society "Affiliation" Lecture Competition: (a) Illustrated lecture descriptive of a tour (b) Illustrated technical lecture. Particulars from the Secretary R.P.S., 66, Russell Square, London, W.C.

WARWICK Competitions.—The result of the September competition is as follows:—First prize, £10: E. C. Winney, 34, Mornington Road, Leytonstone, London, E., "Harvesting." Donation, £5, to the Woodford Photographic Society. Second prize, £5: Miss Marian Silverston, 24, Clarendon Road, Edgbaston, Birmingham, "Study, Head of a Boy." Donation, £2 10s., to the Birmingham Photographic Society. Entries for the last competition this season must reach the Warwick Dry Plate Company, Warwick, not later than October 16.

Photo-Mechanical Notes.

Transferring Image to Copper for Engraving

A correspondent, "A. S.," sends us a copper plate carry a collodion film, and asks how to do similar work. The im on the copper is certainly a wet-plate film. Any ordin collodion will do for the purpose. We have found a 2 cent. celloidin collodion to be the best for the purpose, as is quite tough, and will therefore stand handling. A suitable formula is:—

Celloidin	20 grammes.
Ether	500 c.c.s.
Alcohol	500 c.c.s.
Ammonium iodide	6 grammes.
Cadmium iodide	6 grammes.

The collodion should be coated on a piece of taled glass and, after sensitising, exposure, and development, the negative is soaked in weak acetic acid (say 5 per cent). The part be lifted is then cut out from the rest, and a piece of dam paper, cut to that size, placed over the film, which can then be lifted up. It can then be laid down on the copper. necessary to reverse, it should first be transferred to another piece of paper. It will be found that the collodion will cut without chipping if the film has been soaked sufficiently in acetic acid. In wood engraving, it is usual to coat the wood block with:—

Gelatine	2 parts.
Potassium bichromate	2 parts.
Water	100 parts.

Into this some ground lamp black is put, sufficient to make it quite black. This is then rubbed on the wood block to make a black background. It would, however, be more desirable and probably quite easy in the case of copper to blacken by chemical means. A well-known formula is a mixture of solutions of copper nitrate and silver nitrate, each 200 gr. per ounce, in which the clean copper is immersed, and heated strongly on removal.

Thursday Evening Lectures at Bolt Court School of Photo Engraving.

The following is the list of lectures to be delivered during the winter at the Bolt Court School, Fleet Street, E.C., from November 16 to March 1. Preliminary to these discourses on particular subjects, a course of five lectures on the chemistry of photo-engraving will be delivered by Mr. Kenneth Mees, B.Sc. Admission to any lecture is obtainable on application to Mr. A. J. Newton, Principal of the school. November 16, 1905.—A. J. Newton: "Ten Years' Work of the L.C.C. School of Photo-Engraving and Lithography." November 23, 1905.—Arthur Cox (Arthur Cox Illustrating Co., Ltd., Birmingham): "Photo-Engraving as a Business." November 30, 1905.—Edwin Bale, R.I.: "The Influence of Illustration in Modern Life." December 7, 1905.—R. Burch: "The History of Colour Printing in England." December 14, 1905.—Frank Colebrook: "Latest Developments in Multi-Colour Printing." January 11, 1906. Carl Hentschel: "The Future of Illustration." January 18, 1906.—E. W. Foxlee: "The Use of Bichromate Salts in Photography." January 25, 1906.—F. E. Witthaus: "English and Continental Collotype Compared." February 1, 1906.—F. T. Corbett: "The Production and Distribution of the Picture Postcard." February 8, 1906.—Arthur Dix: "The Present Position of Wood Engraving." February 15, 1906.—Wm. Gamble: "The Reproductive Arts in America." February 22, 1906.—Edward F. Strange: "Artistic Lithography." March 1, 1906.—Graily Hewitt: "Caligraphy and Illumination." March 1, 1906.—A. J. Bull: "The Photographic Lens." All lectures commence at 8 p.m.

"Carl" of Fleet Street.

Mr. Carl Hentschel has been persuaded by the editor of "M.A.P." to write a chapter of autobiography, and what he has to say of his early days with his father makes good reading for those who associate "Hentschel" with the prosaic business of photo-engraving. The elder Hentschel "was an American citizen. He invented the Gladstone bag and the paper collar, and numerous other inventions may also be placed to his credit, the patents ranging from preserving meat, making ivory out of milk, photography on porcelain, engraving on glass, and various autotype processes. He was the pioneer of process engraving, which altered the whole character of the newspaper world, and fairly revolutionised illustrated journalism . . . My father, who was an expert photographer and chemist—trained in the former capacity under Daguerre, in the latter under Baron Liebig and Professor Hoffmann—about this time turned his attention to wood engraving, and invented two or three processes for photographing on wood. I was enlisted at the early age of fourteen to assist in the practical work, and I look back with interest to a little office on the top floor in Fleet Street, near Red Lion Court, where I acted as office boy, messenger, and general workman to my father, while I was still in knickerbockers. But my father had the foresight to see that wood engraving would be superseded, and all his spare time was spent in seeking to perfect the mechanical method of reproducing illustrations on zinc, now called process work." Mr. Hentschel looks back on those early struggles with relish—the feeling, perhaps, is strengthened by improbability of their return—and recalls how his dinner was a slab of phenomenally heavy pudding and a cup of coffee, how he worked usually from 7 to 12, and how eventually he built up his present business, in which employment is found for 400 hands. Mr. Hentschel claims a record as a "first nighter" at the theatres. Since 1879 he has missed only a few of the first productions, but he thinks the happiest days of his youth were spent on the river. He was the "Harris" of Mr. Jerome's "Three Men in a Boat."

Process Instruction at Manchester.

The syllabus of the photographic and printing crafts' department of the Municipal School of Technology, Manchester, reaches us from the Director, Mr. Charles W. Gamble, to whom the equipment and organisation of this important centre of instruction in "process" must be credited. The lecture and laboratory courses include pure photography, orthochromatic and three-colour work, half-tone and line engraving, lithography, and other branches of photo-mechanical reproduction. A course of practical instruction is given, extending over two sessions, which deals with typical photo-mechanical processes. The instruction is tutorial, and of a strictly practical character, and each student attending will have full opportunity given to him for carrying out the various operations in the processes as shown. Those requiring instruction, and living within reach of Manchester, are fortunate in having access to a school where they may be taught the technical side of their craft at almost nominal fees.

New Books.

"Successful Negative Making." By T. Thorne Baker, F.C.S., F.R.P.S. London: Marshall, Brookes, and Chalkley, Limited. 6d.

The price of Mr. Thorne Baker's manual may mislead some into the belief that it is only for the beginner person; but a study of its pages shows us that the author refuses to descend to the depths of ignorance in which the photographic neophyte is reputed to abide, for we find him assuming a knowledge of the ordinary way

of doing a thing, drying a negative for example, and turning aside to give hints and precautions on methods which the more advanced photographer may study to his profit. The text of the book is quite on the modern lines of orthochromatism, etc., though we should have thought "combined development" was out of place in a text book, and the selection of intensifiers is rather curious.

"Eder's Jahrbuch, 1905." Halle: W. Knapp. Price M 8.

We substitute the conveniently brief title of "Eder's Yearbook" for that of "Jahrbuch für Photographie und Reproduktionstechnik," which appears on the cover, for Dr. Eder has associated himself so intimately with this yearly digest of photographic literature that the shorter phrase is equally descriptive of the contents. Though we may be accused of leaning towards the photographic literature of Germany, we cannot yet disguise our admiration of the summary which is produced each year under Dr. Eder's direction. The arrangement and completeness of the current volume appear equal to those of its predecessors. The original contributions, however, are less interesting to us than usual, for a large proportion are on the more recondite aspects of scientific photography; but the volume, as a whole, presents the year's work in all branches of photography in the most systematic way. Readers of German can want no better work of reference.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes."

The following applications for patents were made between September 18 to 23:—

PHOTOGRAPHIC TRANSFERS.—No. 18,888. A new method of transferring photographic transfers to the surface of any substance for the purpose of printing therefrom. Edward Richard Ede, 74, Ravensbourne Road, Catford, Kent.

DARK SLIDES.—No. 19,032. Improvements in photographic dark slides, Gustav Geiger, 4, South Street, Finsbury, London.

FLEXIBLE DARK SLIDES.—No. 19,165. Improvements in dark slides made of flexible materials, and in camera attachments for receiving same. Richard Schütttauf, Jena, Germany.

THREE-COLOUR FILTERS.—No. 19,902. Process for the manufacture of three-colour screens for use in colour photography. Robert Krayn, 322, High Holborn, London.

ENLARGERS.—No. 19,224. Improvements in and connected with photographic enlarging apparatus. Max Schütze, 24A, Luisenstr., Berlin.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

MOUNT.—No. 12,273, 1905. The claim is for a mount giving a *passerpartout* effect without cutting the matt portion proper or to produce a machine-made flat-backed mount having any kind of border, a central countersunk portion for the print and a plain or coloured inside bevel. The mount comprises three essential parts, viz., a countersunk surface sheet, a cut-out filler and support, and a back, all united to make a solid finished article. In manufacturing these mounts, a sheet of paper is subjected to pressure beneath a suitable die to countersink a central portion, corresponding to the size of the picture to be mounted. For the filler one may employ one or more sheets of the cheapest cardboard obtainable, and cut out the filler to form an opening

which will just receive the central portion and its inclined walls, leaving the outside of the bottom of the central portion flush with the outer surface of the filler. The object of the filler is to support the border portion of the outer flexible sheet and the bevelled portion, and to give the necessary rigidity and strength to the mount. The back sheet is then pasted on to the filler to support the central part and give finish to the mount. The outer edges of the mount may be bevelled in the usual manner. *Eston Saxe Cheney, 1444, Fourth Avenue, Oakland, California, U.S.A.*

PLATES IN ENVELOPES.—No. 11,786, 1905. The invention refers to a system of carrying plates in envelopes, the latter being transferred to a holder, withdrawn (leaving the plate inside), and re-inserted, to enclose the plate after exposure. The holder or exposing chamber contains a receiving shell, into which the envelope containing the plate is inserted. The plate is transferred to this slide without access of light, and is removed from it after exposure, the mechanism necessary for these operations requiring the drawings given in the patent specification for its proper explanation. *Jesse Daugherty Lyon, Farmers' National Bank Buildings, Pittsburgh, Alleghany, Pennsylvania, U.S.A.*

PIGMENT PRINTING.—No. 26,456, 1904. The basis of the new process is the fact that neutral and insoluble chromates, e.g., those of copper, cobalt, mercury, etc., insolubilise a layer of colloid and pigment when acted on at the same time by dilute acids. Paper is sensitised with a ferric salt, such as does not form (when reduced) a precipitate with bichromate, but does so with neutral chromates. A visible image of ferrous salt is obtained, and, on treatment with a bichromate, reduces the latter to chromate the latter at once yielding a precipitate with a metallic salt, such as sulphate of copper, present in the paper. The precipitate thus forms on the parts acted upon by light, and the paper is then washed for a short time and pressed against a pigment paper impregnated with a dilute acid. After some hours development is done in hot water in the usual way, with the result of an unreversed pigment print. Suggested formulæ for the process are:—Coating mixture.—1000 parts of water, 10 parts of gelatine, 5 parts of chrome alum, 100 parts of ferric chloride, 100 parts of citric acid, and 100 parts of copper chloride; dry in the dark. To prepare a copy, expose in daylight under a negative until the picture is clearly visible. Immerse the copy for 1-2 minutes in a solution containing 5 per cent of bichromate of potassium, wash for 5 minutes under the tap, to remove the excess of bichromate, and then press the copy under dilute sulphuric acid (5:10000) against a pigment paper (coated with gelatine or gum and a dye). Squeeze the two papers together to remove the air bubbles, and press between blotting-paper for about 3-6 hours. Then soak in hot water, until the picture can be readily detached from the pigment paper, and wash the former with hot water until all the parts not acted upon by light have disappeared and a very distinct picture is visible. *H. E. Newton, for the Farbenfabriken vormals, Frederick Bayer and Co., Elberfeld, Germany.*

GELATINE-COLLODION FILM.—No. 10,372, 1905. A gelatine film protected on either side by a layer of nitro-cellulose is made as below described, instead of by the methods hitherto used of immersion of the film in nitro-cellulose solution, or of coating nitro-cellulose, gelatine, and, again, nitro-cellulose on a glass plate. Two component films are prepared by coating upon an appropriate smooth base a gelatine solution, and, after drying, coating upon this again a solution of nitro-cellulose; when the double films are dry they are stripped from their base, the gelatine surfaces brought together in a slightly moist condition, squeegeed together, and

thus brought into intimate combination. If such a film is to be employed for photographic purposes, one of the component films is coated before stripping from its support with a photographic gelatine emulsion. This process produces films composed of a double gelatine film with a protective coating of nitro-cellulose in intimate combination with the gelatine surfaces upon both sides, which withstand the action of the photographic baths and solutions and show no tendency to curl. *John Henry Smith, 417, Seestrasse, Zurich.*

New Materials.

Folding Screen Mounts and Flexible Album. Made by Kodak, Ltd., 57-61, Clerkenwell Road, E.C.

The Louis XV. screen mount is a new departure and is founded on the design of a three-fold Louis XV. screen. Three slip-in mounts of appropriate shape are fastened together with red silk ribbon hinges, the colour being a quiet shade of green with lithographed design. Openings of different shapes are supplied, and when filled with photographs the mount looks very attractive. Another type of mount is the "Watteau" mount. This is similar to the "Louis XV.," but the openings differ in shape. They are both supplied for quarter-plate and 3a F.P.K. or postcard pictures at sixpence each.

The Flexible Album is a very neat variant of the usual album. It is of the paste-in variety with leaves of thick art green paper. The covers are stout but flexible, and the single word "Prints" stamped in gold on the outside is not obtrusive. The album is made in two sizes, No. 1, with twenty-four leaves, measuring 6½ in. by 5 in., and No. 2, with fifty leaves, 10 in. by 7 in., the prices being 1s. and 2s. 6d. respectively. A pocket is provided inside the back cover for the accommodation of loose prints.

"Chess" Brand Bromide Paper. Made by Photographic Materials, Ltd., Rickmansworth, Herts.

Samples of this latest claimant for notice by bromide workers have been sent us. The paper is made in four grades—rough, smooth, glossy, and cream-tinted. It is well coated, and works very evenly, good black tones being obtained with any normal bromide-paper developer. The paper is rapid, and needs a very short exposure, about six seconds at a distance of 3 ft. from a 16 c.p. incandescent electric light giving fully exposed prints with a negative of normal density. The following one-solution developer is specially recommended by the makers:—Metol 10 grains, hydroquinone 30 grains, soda sulphite 330 grains, soda carb. 330 grains, water 20 oz., 10 per cent. solution of potassium bromide 20 drops. The paper is sold in the usual sizes at popular prices.

The Lambton C.C. Printing-out Paper and Postcards. Sold by Chad Hodgson, 5, Wade Street, Leeds.

The Lambton C.C. paper is a well-made production that prints rapidly and tones to a good colour in the sulphocyanide toning bath. There appears to be little indication of blistering when using this paper, although special instructions are given for its prevention. The postcards are also reliable in this respect, and both in the glossy and matt varieties give very pleasing results with little trouble. The paper is supplied in the usual cut sizes and sheets.

"Rajar" Bromide Paper and Postcards. Made by Rajar, Ltd., Moberley, Cheshire.

The latest introduction of the "Rajar" Company takes the form of a first-class bromide paper. It is specially intended for enlarging by artificial light, and our tests prove it to be rapid for contact

work. Good black tones appear to be easily obtainable. The paper is made in five grades, and sells in rolls or packets at the usual prices.

"Primoids." Made by W. Butcher and Sons, Farringdon Avenue, London, E.C.

These chemical preparations are in the form of small circular tablets, and are sold in glass tubes. They are easily soluble in water, and make standard developers and toning solutions with very little trouble. They are at present supplied in four varieties, and are not expensive.

In our hands, "Primoid" Metol Quinol developer proved clean and quick-acting for both plates and films, and the "Primoid" Gold Toning and Fixing appear to give a reliable combined bath.

New Apparatus, &c.

The Victor Circle Trimmer. Sold by Charles Johnson, High Street, Gillingham, Dorset.

This is a well-made, practical piece of apparatus for rapidly cutting circular prints or thin mounts. Glass circles are supplied with central bosses to take a loose arm carrying a wheel cutter at one end. At the other end of the arm is a pin which engages in a hole in the central boss. The glass plates are only used to hold the print down

firmly, and not as a guide for the cutter. Circles of any diameter up to 9 in. can be cut, and the size is easily regulated by means of a sliding clamp on the loose arm.

It is a useful little piece of apparatus, and is now stocked by most of the leading houses.

The "Minimum Cameo" Folding Hand Camera. Made by W. Butcher and Sons, Farringdon Avenue, London, E.C.

This little camera, just introduced by Messrs. Butcher, can claim

to be one of the smallest quarter-plate folding cameras on the market. It measures but $4\frac{1}{4}$ by $5\frac{1}{4}$ by 1 in., and is exceedingly light. When open, however, it will be found to possess all the

attributes of a complete folding camera, and it seems remarkable how so much can be compressed into such a small compass. The lens is a rapid aplanat of excellent covering power, and a reliable ever-set diaphragmatic shutter is included. A hooded focussing screen can be used, and a rack and pinion forms part of the base board for fine focussing. Rising and falling and cross-front movements, and a neat little brilliant finder forms part of the equipment. The plate-holders are well made of metal, and hold one plate each. They are supplied in a neat little carrying case. The entire outfit is very dainty, and excellently constructed. Full particulars will be supplied by Messrs. Butcher on application.

A New Model 1a Pocket Folding Kodak. Made by Kodak, Ltd., 57 61, Clerkenwell Road, London, E.C.

This latest introduction of the Kodak Company is an improvement on the earlier form of the popular little camera known as the 1a F.P.K., and the features we favourably commented upon when recently reviewing the No. 1 F.P.K. (New Model) have been embodied in this pattern. The working parts are entirely enclosed by the folding base board, and this base, which now protects the hitherto exposed lens and shutter, is so connected with the front that the action of opening the camera instantly brings the front into

the correct position for work. Only this one operation is necessary, therefore the camera can be said to be always ready for immediate use. From its design the camera is necessarily of fixed focus, and the lens, which is capable of giving excellent definition at full aperture, is neatly mounted in an ever-set shutter. The camera takes pictures measuring $4\frac{1}{4}$ by $2\frac{1}{2}$ in., and, being constructed on the daylight loading and changing principle, can be charged with spools for twelve or any less number of exposures. As a pocket film camera it would be hard to beat, and if Messrs. Kodak could be persuaded to fix some sort of focussing device to the lens its utility would be even greater. The price is only 50s., and the little camera should prove just as popular as its predecessor.

CAMBRIDGE and District Photographic Club will hold its first "open" exhibition in the Guildhall Buildings, Cambridge, on October 31 and November 1 and 2, 1905. The judges will be Messrs. A. Horsley Hinton and H. Snowden Ward. The awards will take the form of specially-designed bronze plaques, silver plaque being awarded to the best picture in the members' and open classes. As Cambridge possesses a very large class of University residents who are very much interested in art, the exhibition ought to be a great success, both from the promoters' and exhibitors' points of view. Arrangements have been made to forward exhibits to the Ipswich exhibition free of charge. Schedules and all information may be obtained from the Secretary, Mr. T. J. Sowdon, Sunny Side, Guest Road, Cambridge.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Oct.	Name of Society.	Subject.
6.....	Blackburn Camera Club	Development by Pyro-Soda. Mr. W. A. McLean.
7.....	Glasgow Southern Photo. Assn.	Outing to Milngavie.
7.....	Woolwich Photographic Society	Outing to St. Paul's Cray.
7.....	Kinross Park Camera Club	Outing to Gleniffer.
9.....	R.P.S. Exhibition New Gallery	Picturesque Devonshire. Mr. John A. Hodges, F.R.P.S.
9.....	Southampton Camera Club	"Westminster Abbey." Part I.—Its Evolution and Historical Associations. Illustrated. Mr. E. W. Harvey
9.....	South London Photo. Society	Paper, Hon. M.S.A. (London).
9.....	Luton Camera Club	"Cameras and Apparatus." Mr. W. Page.
9.....	Leek and District Photo. Soc.	"Auto-Paste." The Autotype Co.
9.....	Barrow Naturalists' Field Club	Development of Plates, by Messrs. Howarth, Nithsdale, and Prince.
10.....	R.P.S. Exhibition New Gallery	"Recent Work Among the Birds." Illustrated. The President.
10.....	Sheffield Photographic Society	Presidential Address: "By-Paths of Photography." Major Gen. J. Waterhouse.
10.....	Halifax Camera Club	"What I Saw in a Dutch Fishing Village." Mr. T. P. Brogden.
10.....	Thornton Heath Photo. Society	"P.O.P. from Negative to Mount." Mr. J. H. Hanson.
10.....	Leeds Photographic Society	Demonstration of Kodak Specialties, by Kodak, Ltd.
10.....	Darlington Camera Club	"Through to Venice, the Queen of the Adriatic." A Lantern Lecture with Dissolving Effects, Depicting Sunrise from Pilatus Summit, and Venice by Night. Mr. A. A. Pearson.
10.....	Gateshead Camera Club	Grand Opening Night and Social Evening, with Music, and Exhibition of Lantern Slides.
11.....	Photographic Club	"The Rapid Printing of P.O.P. by Development." Dr. A. W. Blacklock, M.D.
11.....	G.E.R. Mechanics' Institution	"Some New Applications of Velox." Mr. A. W. Green.
11.....	Huddersfield Nat. and Ph. Soc.	"The Amateur Photographer 1904 Prize Slides."
11.....	Boro' Poly. Photo. Society	"Through Canada from the Atlantic to the Pacific." Mr. Ernest Slater.
11.....	Hull Photographic Society	Summer Outings Print Competition.
12.....	Handsworth Photo. Society	"Yorkshire Minsters." Mr. C. B. Howdill, A.R.I.A.
12.....	London and Prov. Photo. Assn.	"Printing on Bromide Paper." Demonstrated by Mr. E. G. Collins.
12.....	Glasgow Eastern Ama. Ph. Assn.	"Gum Bichromate." Mr. J. C. S. Mummery, F.R.P.S.
12.....	R.P.S. Exhibition New Gallery	"Gum Bichromate." Dr. Andrew Richmond.
		Pictures in Colour by Triple Projection. Sir W. Abney, K.C.B., D.C.L., F.R.S.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

MEETING of the Liverpool Branch of the P.P.A.—The first meeting of the session was held September 29, G. Walmough Webster occupying the chair. The secretary reported progress in the matter of the promotion of a Professional Photographers' Club. The matter had been postponed at an earlier meeting, and it was now regretfully resolved that it be postponed indefinitely owing to the limited support the circulars had evoked. The secretary was instructed to convey through this report acknowledgments and thanks to those photographers who had replied favourably to the circular.

Mr. Priestly passed round a series of interesting and very successful photographs he had taken of the recent eclipse of the sun, giving details of the circumstances under which they were taken; he also showed the members some pictures of entomological interest, notably pictures of a caterpillar feeding, and when disturbed simulating a twig of the branch he was feeding on.

Mr. Webster commented on the foolish action of many photographers in parting with their copyrights at absurdly low prices, and gave some interesting personal experiences. Mr. Mowll pointed out how on this point, as on many others, lack of concerted action was altogether at the root of the grievance, thereby enabling the purchaser to play off one photographer against another to their disadvantage. It was announced that at the next meeting there would be a discussion on the platinotype process.

THE Cripplegate Photographic Society's new session commences on Monday, October 9, with a demonstration by J. C. S. Mummery, F.R.P.S., on gum-bichromate.

WORTHING CAMERA CLUB.—The Worthing Camera Club has entered upon a new venture, which should prove successful. Club rooms have been secured in Liverpool Terrace, where all necessary accommodation in the shape of dark-rooms, committee and lecture halls, etc., will be provided. It is hoped that the enterprise of the committee will result in an increased membership. It is possible that the subscription will be increased for new members, but the extra benefits will justify it.

WARRINGTON PHOTOGRAPHIC SOCIETY.—The second of the winter series of demonstrations was given on Tuesday last by Mr. Kenneth F. Bishop, who dealt with the whole subject of postcard printing.

ILFORD AND DISTRICT PHOTOGRAPHIC SOCIETY.—On Monday evening last the autumn session of this society was opened by a meeting in the Cranbrook College. Mr. A. E. Colledge gave a lantern lecture on "Common Insects as seen through the Microscope."

BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.—At the annual general meeting on September 27 the following officers were elected: Mr. A. Bedding (president), Mr. W. Page (vice-president), Mr. F. W. Crutenden (treasurer), and Messrs. A. J. Blane, J. Bullock, E. W. Burch, P. C. Cornford, C. Inskeep, J. N. Spare, A. J. Sturgess (committee). The secretarial work is now in the hands of Messrs. G. W. Francis and G. Wynne, to whom communications may be addressed, at 103, Borough Road, S.E.

CROYDON CAMERA CLUB.—September 27. An almost record attendance of members assembled on this, the opening night, to hear Mr. F. J. Mortimer lecture on Marine Photography. The president, Mr. W. H. Smith, in a few opening remarks, said that he was glad to note that the club was going stronger than ever. A large number of new members had recently joined, and the club was well represented at the R.P.S. Exhibition, and also in evidence at The Salon. Perhaps the scientific aspect of photography, and its unsullied technique, attracted him more strongly than the "art" side. They had several members doing, and capable of doing original work, and he should be sorry to see research work in any way neglected.

NEWCASTLE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.—The twenty-fourth annual meeting of the above association was held at Crosby's Cafe, Northumberland Street, Newcastle, on Tuesday of last week. The reports of the hon. secretary and the treasurer were both adopted, and the election of the office-bearers took place as follows:—President, Mr. J. W. Dyson; vice-presidents, Messrs. W. E. Cowan, J. J. Kirkwood, W. Dotchin, and J. H. Holmes; council, Messrs. C. E. Barkas, W. Parry, W. S. Corder, W. L. Cookson, D. A. Lowery, T. M. Clague, W. G. Lewis, E. Holmes, D. Wait, and E. G. Lee; lanternists, Messrs. T. Bulman and J. H. Harbottle; honorary secretary, Mr. F. Milburn; assistant honorary secretary and treasurer, Mr. A. Scott; Federation delegates, Messrs. J. W. Dyson and F. Milburn; Affiliation delegate, Mr. J. Brown.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—September 28. Mr. E. R. Human in the chair. Mr. C. H. Hewitt, of the Photographic School, Regent Street Polytechnic, gave a lecture on portraiture. Confining himself to portraiture out of doors and in ordinary rooms, he remarked on the tendency of the former to flatness and of the latter to hardness. Relief was obtained out of doors by the old device of putting the sitter in an angle of two walls, so as to cut off light from one side. A large umbrella or a child's hoop covered with canvas served to intercept the excessive toplight. Outdoor portraits, said the lecturer, were better if frankly aiming at an outdoor effect. Attempts to obtain the appearance of por-

is taken in a studio were rarely successful. In indoor work similar expedients of lighting were mentioned, stress being laid on a suitable angle of the "line of light," (i.e. the line along which it falls on the sitter), and the "line of vision" (i.e. the straight line between sitter and camera). A good position for the sitter was on this angle was 45 deg. A method of softening contrasts by increasing the intensity of the high lights without increasing the necessary exposure was to interpose a diffusing screen of muslin or finer's tracing cloth between the light and the sitter. The alternative method was to lighten the shadows by reflecting more light on them, in doing which too white or too near a reflector was to be avoided, as it introduced secondary lighting on the face, giving high-lights, which were comparable with those from the principal source of illumination. A grey and somewhat distant reflecting screen was therefore better, and in line with the suggestion of H. P. Robinson that the walls of the studio should be turned into reflectors by being papered a light grey. Whatever reflector was used, it should be employed to carry on the illumination of the main source of light. In regard to negative-making, Mr. Hewitt mentioned that to obtain a negative perfect for platinotype printing the commercial method was to expose and develop for good half-tones, but otherwise not of the strength at the ends of the scale for platinotype. It is easy to turn out a negative such as this, and the finishing touches of density and shadow are put in with the pencil and knife. Referring to the defects which occurred more or less in all sitters' portraits, and which the photographers had to disguise, the lecturer mentioned the crooked nose—photograph that side of the face from which it turns; unlevel eyes—have the lower eye the further from the camera; eyes of unequal size—the larger eye should be placed nearer the camera; and the "narrow-slit" type of eye, which was treated by inclining the chin of the sitter downwards and making him look upwards to the lens, the eye being thus expanded. The persons were best photographed when leaning forward, as the thick and double chin then showed the fat to a less marked extent. The proposition of Mr. J. S. Teape a vote of thanks was accorded Mr. Hewitt.

SOUTHAMPTON CAMERA CLUB.—The winter session of this club was inaugurated on Monday, the 26th inst. by the Rev. H. W. Dick, of Manchester, who lectured on the subject of "Art by Photography." The lecturer started out from the point that, while the use of the camera in the way of simple record and work of purely passing interest is quite understandable, yet that the true use of photography was the more serious attempt to produce works of art by means thereof. Disclaiming all ability to produce a simple phrase embodying a perfect description of what art is, he urged that art is the embodiment of some means and in some form of an idea or feeling which is in the man himself. He pointed out that art had nothing to do with the means by which it was expressed, and also, by various illustrations, how the ability to reproduce with great faithfulness any familiar natural scene might prove a man a wonderful craftsman, while he might be devoid of artistic sensibilities. Carrying on his principle into the practice of photography, the lecturer urged his audience to use their skill with the camera as a means of carrying out their artistic conceptions, so that with them art should live by its means. He pointed out that all workers who professed to be serious in their work should set out to find material to embody their previously conceived ideals, and drove home the point by explaining the inartistic procedure of searching for a title for a print instead of working up to the title or idea previously chosen. Coming to his especially favourite work of figure study, the lecturer proceeded to urge four chief requirements: first, simplicity of subject; second, the subduing of detail in surroundings; thirdly, accentuation of lighting and of characteristics; and, lastly, reality of occu-

pation in the model. Afterwards he proceeded to show a fine selection of slides illustrating his principles.

FIXTURE LISTS AND EXHIBITION PROSPECTUSES RECEIVED.

THE winter syllabus of the HULL PHOTOGRAPHIC SOCIETY points to the fact that the council have had the requirements of the beginner well before them when drawing up the list of fixtures, and a large and varied programme of good things has been prepared. We note a lecture on "The Principle of Composition in Pictorial Art," by J. Somerscales, the well-known painter. This should prove a very instructive evening.

THE EDINBURGH PHOTOGRAPHIC SOCIETY is again well to the fore this year with an attractive winter programme, and the SHEFFIELD PHOTOGRAPHIC SOCIETY's syllabus takes the form of a well got-up little booklet. Interesting lectures and demonstrations are announced for every Tuesday, from October 3 to May 1, 1906, and a series of "elementary nights" appear to be a feature. The PHOTOGRAPHIC SECTION OF THE G. E. R. MECHANICS' INSTITUTION, Stratford, usually has an attractive list for the winter session, and this year it is well up to standard. Fixtures are announced for every Wednesday from September 27 to May 9, 1906.

THE GLASGOW SOUTHERN PHOTOGRAPHIC ASSOCIATION's winter programme also shows evidences of considerable vitality among the members, and the THORNTON HEATH PHOTOGRAPHIC SOCIETY has a fixture list which promises several interesting evenings, among which we note "Soirée Dansantes," "Conversational Evenings," a lecture on "Mud Island and its Flats by One of Them," and a humorous demonstration of spirit photography.

THE CHELSEA AND DISTRICT PHOTOGRAPHIC SOCIETY, the WANDSWORTH CAMERA CLUB, and the JERSEY PHOTOGRAPHIC SOCIETY have each produced a card of fixtures that indicates the healthy state of the respective societies.

THE REDHILL AND DISTRICT CAMERA CLUB, the HANDSWORTH PHOTOGRAPHIC SOCIETY, and the SHEFFIELD FRIENDS' SCHOOL PHOTOGRAPHIC SOCIETY have also published their winter programmes indicative of a good season's work; and the GATESHEAD CAMERA CLUB and the BARROW-IN-FURNESS NATURALISTS' FIELD CLUB have lists of interesting fixtures.

Exhibition entry forms and particulars have been sent us by the following societies:—

SOUTHAMPTON CAMERA CLUB.—Last day for entries, November 11. Hon. sec., S. G. Kimber, "Oakdene," Highfield, Southampton.

EDINBURGH PHOTOGRAPHIC SOCIETY.—Last day for entries February 10, 1906. Hon. sec., J. S. McCulloch, 3A, North St. David Street, Edinburgh.

BURNLEY CAMERA CLUB.—Entries close November 8. Hon. sec., F. Pinder, Burnley Camera Club, Mechanics' Institute, Burnley.

GUISBOROUGH FINE ART SOCIETY.—PHOTOGRAPHIC SECTION.—Entries close January 31, 1906. Secretary, Geo. Page, 24, Westgate, Guisborough.

TRING CAMERA CLUB.—Entries close January 1, 1906. Hon. sec., J. Owen Raymond, Frogmore Street, Tring.

ISLE OF THANET PHOTOGRAPHIC SOCIETY.—Entries close November 11. Hon. sec., L. G. Hodgson, 58, Queen Street, Ramsgate.

IMPROVEMENTS in Edinburgh Photo Society Premises.—During the summer recess extensive alterations have been carried out on the society's premises. In place of the small dark-room there is now a spacious apartment containing every fitting which the most exacting and enthusiastic photographer could desire. One side has been fitted for four bromide workers, and the other for six plate or film workers, whilst down the centre a screen has been placed with tables and racks on each side, at the end of which washers have been erected. Electric light has been fitted throughout the premises, and in the dark-room each worker has a light controlled by a separate switch for his own use.

News and Notes.

LECTURES at the R.P.S. Exhibition.—The following lectures will be given at the New Gallery during the ensuing week:—Saturday, October 7: "Nine Thousand Miles in Five Weeks," by R. Child Bayley, F.R.P.S.; Monday, October 9: "Picturesque Devonshire," by John A. Hodges, F.R.P.S.; Thursday, October 12: Pictures in Colour by Triple Projection, by Sir W. Abney, K.C.B., D.C.L., F.R.S.

POSTCARD Vagaries.—"Truth" last week had a word or two to say on the present chaotic state of the postcard regulations in the postal authorities' scheme of jurisdiction. The editor remarks:—"I have received sundry letters drawing attention to the absurdity of the international postal regulations with regard to postcards. There is, for instance, a bewildering diversity of practice respecting the use of the face of the card for correspondence. Here, the left side of the face of the card may be so used for inland, but not for foreign postage. In some countries abroad the same rule is enforced; in others, cards with correspondence on the face of them are passed in certain specified cases for foreign postage, though not for the United Kingdom. Again, any card within the regulation size, bearing a halfpenny stamp, is accepted here as a postcard for inland postage, regardless of the question whether the words "post card" are printed across it. For foreign postage, however, it must have this printed endorsement. Everybody is supposed to know the regulations, but few people do so, and all this confusion leads to the vexation and expense of constant surcharges for unwitting mistakes. Surely it should not pass the wit of the authorities of the Postal Union to devise a uniform code in these and similar matters."

At the Whitechapel Art Gallery, High Street, Whitechapel, E., a photographic exhibition is to be held this autumn. The exhibition will be open free, daily from 12 noon to 10 p.m., for four weeks from the end of October. The Trustees of the Gallery will undertake the expenses of collection, and will insure the exhibits if wished. The exhibits will be collected about October 20, and invitations are being sent to all the leading British workers for loan of their pictures. The Gallery, which is within fifteen minutes' walk from the Bank, was opened by Lord Rosebery in 1901. Since then sixteen exhibitions have been held, and nearly 2,000,000 people have visited the Gallery, so that, besides providing a source of interest and pleasure to the poorer people of East London, such an exhibition as the one now being organised offers an opportunity of making pictorial photographic work very widely known to people in all parts of London. A section will be devoted to the early development of photography, and any exhibits illustrating this will be welcomed. Charles Aitken is the Director of the Gallery, and all communications should be addressed to him as above.

NATURE Lectures.—Mr. F. Martin-Duncan, whose unique photographs of animal life have been so widely admired, notifies that he is prepared to lecture on one or two subjects during the present season. The lectures at present arranged are "Pond Life," "Denizens of the Deep," "Devil Fish and Kraken," and "Flesh-feeding Plants," and "With Microscope and Camera." Appropriate selections from the marvellous series of animated pictures taken by Mr. Duncan with the Urban-Duncan micro-bioscope, and produced with extraordinary success by the Charles Urban Trading Company, Ltd., can be included in these lectures by special arrangement. We can

scarcely promise a greater treat of interesting discourse and sensational illustration than one of these lectures.

THE Southern Exhibitions.—The southern exhibitions have each their position amongst the foremost of provincial exhibitions for the fourth year the Southampton, Hove, and Southsea Societies are co-operating together. To those exhibitors who intend exhibiting at all three exhibitions, free conveyance of exhibits is offered between the Hackney, Southampton, Hove, and Southsea shows, and as the first-named Society collects exhibits free from the Royal and Salon, this will be extremely convenient to those whose exhibits are either "hung" or "unhung," are at present at the London exhibitions. The Isle of Wight and Frome Societies also convey exhibits free to the Southampton Exhibition. Each of the Societies has fresh designs for their plaques this year, and a special award in the shape of a bronze salver is offered to the exhibitor who is adjudged the winner of the best collective exhibit in the three shows. The following are the judges for the respective exhibitions:—Southampton: Rev. F. C. Lambert, M.A., F. H. Evans, and A. Horton; Hove: E. R. Ashton, Charles Job, and J. C. S. Mumm; Southsea: Reginald Craigie and H. Snowden. Entry forms and full particulars can be obtained from the respective secretaries, who are:—Southampton: S. G. Kimber, Clarendon, Highfield, Southampton; Hove: A. R. Sargeant, 55, The Drive, Hove; Southsea: F. J. Lawton, 20, Clarence Square, Gosport.

DURING a cinematograph exhibition at a Portuguese theatre the apparatus caught fire, and the building and the one next to it were completely gutted. Our contemporary "The Globe," commenting on the affair, remarks:—"The audience, though annoyed at having their entertainment broken off in the middle, could not but admit that the one substituted for it was worth looking at. No exhibits were given."

Commercial & Legal Intelligence

KODAK CASES.—In the Vacation Court, Mr. Justice Bray was asked for leave to serve notice of motion with the writ in an action brought by Kodak, Limited, against Kearney for next Wednesday. Lordship gave leave as asked.—In the London Vacation Court, before Mr. Justice Bray, sitting as Vacation Judge, counsel applied for an action of Kodak, Limited, v. Hall to serve notice of motion for an injunction with the writ. Counsel stated that it was an action of infringement of trade mark and passing off. Mr. Justice Bray granted the application. There was also down in the paper for hearing, before Mr. Justice Bray in the Vacation Court, a motion in the action of Kodak, Limited, v. Hutchings. Counsel for the plaintiff said that the defendant's counsel had consented to treat the motion as the trial of the action, and to agree to a perpetual injunction restraining the defendant from doing what was complained of, and to pay 40s. damages and costs.

THOMAS WELLS, LIMITED (85,885).—Registered September 1904. Capital, £100 in £1 shares. Object, to carry on the business of chemists, druggists, dyers, oil and colour men, manufacturers of photographic and scientific apparatus and material, etc., and, in particular, to take over the business formerly carried on by the late Thomas Wells at 91, Charlwood Street, Pinlipo.

A. H. TAYLOR AND CO., LTD., has been registered with a capital of £1,000 in £1 shares, to acquire and take over as going concerns the businesses carried on as Alfred Edward Haybury in Liverpool, Manchester, Oldham, Blackburn, Sheffield, and Newcastle as H.

jets, and as Lauder in Liverpool, and to carry on the business of photographers, dealers in photographic materials of all kinds, etc. Registered office: 262, Upper Parliament Street, Liverpool.

PHOTOLITHO Printing-Surface Company, Limited.—Registered September 25 by Robbins, Billing, and Co., 218, Strand, W.C. Capital, £10,000 in £1 shares. Objects: To adopt an agreement with W. Hudson, E. Hudson, and H. B. Hudson; to acquire and work the secret process of photo-zinc lithographic printing referred to therein; and to carry on the business of photo-lithographers, printers, etc. No initial public issue. Registered office, 35, Surrey Street, Strand.

PHOTOGRAPHIC FRAUDS.—The police are seeking a short old man who has secured a large number of half-crowns from poor people in Chichester, West Sussex, and East Hants. The man obtained photographs of their relatives from his victims for the alleged purpose of enlargement, and promised to return in a few days. Weeks have elapsed, but the man has not appeared. He gave an address in Portsmouth, but he is unknown in that town.

MISSING CAMERAS.—A remand was ordered at the Guildhall last week in the case of Ebenezer John Faulkner, an engineer, from Manchester, charged with stealing two hand cameras and a tripod, value about £15, from the premises of Messrs. R. J. Beck, Ltd., opticians, Cornhill. The firm's manager stated that Faulkner was a casual customer, and called at their shop on Thursday afternoon with a large kit bag. After he had been there some time the articles forming the subject of the charge were missed. A policeman was called, and, on the bag being searched, they, it was stated, were found inside. Detective-sergeant Gale stated that he had been to the address of a relative of the accused, and had found there some £40 or £50 worth of stolen property, some of which was identified by Mr. Beck.

Correspondence.

* * * *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

* * * *We do not undertake responsibility for the opinions expressed by our correspondents*

MYSTERIOUS PHOTOGRAPHS.

To the Editors.

Gentlemen,—Noticing the paragraph in "News and Notes" on "Mysterious Photographs," might I add a suggestion which, although very improbable, is not altogether impossible, viz., that the impression was in the glass? I have seen, some years ago, a family group 12 x 10 on the sides of a greenhouse quite plainly; the plates had been previously used at a photographer's.

I do not wish to suggest that plate-makers use old plates; but I do believe there is something in the melting of old negatives which have stood years away and become printed in the glass, but I do not know whether they would still remain or show if the glass plates remained intact after being thrown into the melting with the films on. I should be pleased to hear if this could be so.—Yours faithfully,

IGNORAMUS.

[Our correspondent no doubt refers to the wet-collodion process, in which an image from a previous exposure might frequently re-occur if the glass was not chemically cleaned. We have some recollection of allegations of the same kind having been made against gelatine plates; but we cannot imagine any ground for it. Most probably a double exposure or a pin-hole image is the cause of the mystery.—Ems. B.J.P.]

Answers to Correspondents.

* * * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

* * * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

* * * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*

* * * *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

J. Wheeler, 4, North Street, Hoxham. *Five Photographs of Viscount Turnour.*
J. Joeb, 23, High Road, Bromesbury, N.W. *Photograph of Wive Haired Fox Terrier "Champion Dussy Siren."*

C. W. Pool, 45, Dawson Street, Heywood, Lancashire. *Photograph of Interior of St. Joseph's (R.C.) Church, Dawson Street, Heywood.*

F. Coghill, 31, Carlisle Road, Londonderry. *Photograph, Group of His Grace, Dr. Alexander, Primate of Ireland, and His Grace the Duke of Abercorn.*

Two group Photographs of Irish Church Conference, Londonderry.
W. D. Moss, 3, Castle Street, Cirencester, Gloucester. *Photograph of D. G. Bingham, Esq.*

J. Davidson, 111, High Street, Kirkcaldy. *Photograph for Comic Picture Postcard entitled "The Whole Dam Family."*

R. Shankland, 5, St. Vincent Place, Glasgow. *Photograph of the Crypt of Glasgow Cathedral.*

DEVELOPMENT, ETC.—1. Will you kindly inform me if a fractional development can be recommended for Imperial plate, using the Imperial Standard developer? The above query is for portrait negative. 2. What formula is used for bleaching parts of bromide enlargements after being mounted? I am using ferricyanide and hypo, but that leaves a slight yellow mark.—H. TIMS.

1. We presume you mean "factorial." Certainly the system can be applied to any plate. 2. Add 10 minims 10 per cent. solution of iodine in potass iodide solution and 5 minims 10 per cent. potass cyanide solution to about 1 oz. of water. This forms a powerful and clean bleaching and reducing solution.

R.P.S.—I am desirous of becoming a member of the R.P.S. Will you kindly instruct me what steps I should have to take, or whom I should have to write to?—E. P. G.

Write to the Secretary, Mr. J. McIntosh, 56, Russell Square, London, W.C.

B. ELLIS.—We cannot find any trace of the prints sent anonymously.

PUBLICATION QUERY.—Would you kindly give me your opinion on the following facts? A short time ago I invited a customer of mine, who is rather popular as a sacred soloist) to give me a few sittings for postcards. He approved of the pictures, and we put them on sale. He told me he would want no fee, so I presented him with a dozen or two, but later, when he found they were selling rather well, wanted to know what terms I could give him. I offered him a sum, which he did not think enough. We heard nothing from him for a time, but last week he sent a note telling me to withdraw them from sale, and that any sold or exposed for sale after a date named would be illegal, and I should be liable. My opinion is that we have a right to sell if I wish, and that, as he was invited to sit and would accept no fee (which I can prove by a witness), he has no voice in the matter at all.—INQUIRER.

As the portrait was taken for the express purpose of publication, which the person distinctly understood at the time, and received a number of copies in return for the sitting, we do not see how he can now prevent you from selling the pictures. It seems to us that you have a perfect right to do so.

COPYRIGHT.—Will you kindly answer the following questions for me? A. is collecting materials for a local handbook or guide

and amongst the photographs is one of B. sent by B. for the purpose, the mount of which is marked "Copyright." Can A. have this reproduced without risk, supposing B. to have paid photographer for this particular photograph, and original sitting for same? 2. A lady has given me the copyright of a photograph, and has signed a paper to that effect. If I affix a sixpenny stamp now is that sufficient, or ought it to have been stamped before she signed?—COPYRIGHT.

1. If the photographer was paid for taking the portrait he has no copyright in it unless the sitter formally assigned it to him in writing. B. would know if he did that. 2. The agreement should have been stamped before the lady signed. If you affix a stamp now and get her to sign her name across it that will be sufficient.

RETOUCHING (Reply to Touché).—1. Too minute a touch for the subject, and the wrinkles not cleanly and brightly treated. 2. Same as No. 1, and the line from nostril is smeary, and looks much better in the unretouched—leave its depth in more. 3. Remarks made for Nos. 1 and 2 apply. 4. Not fine enough, and all too flat. Increase your high lights more in every negative you work. 5. Too dirty, and insufficiently fined up and modelled. Your retouching is weak, and you require finishing lessons. Combined with your operating and general experience, your work should secure you an average situation in a second-class firm. Impossible to state salary. You ought to be able to form some idea from the "Situations Vacant" columns of the JOURNAL.

CHARLES MARSHALL.—Our answer was correct. We recommended a lens which was not *chromatic*. The definition of the print you send is not good enough for a properly corrected lens—i.e., if the negative has good definition.

INSTRUCTION IN THREE-COLOUR.—I want to make negatives for the three-colour process. Will you please tell me (1) where I can learn the method; (2) or is there a book on the subject, giving practical details of the plates, dyes, light filters, etc., employed?—MARYPORT.

1. Bolt Court School of Photo-Engraving, Fleet Street, E.C.; Photographic School, Regent Street Polytechnic, Regent Street, W. 2. "Hübl's Three-Colour Photography" (Penrose and Co.).

PROCESS.—Will you please inform me who are the makers of apparatus required by a newspaper printer to reproduce photographs in his newspaper in Africa? Are there any books published giving instructions in the art?—G.G.B.

Presumably your inquiry relates to materials for process block making. Messrs. Penrose and Co., 109, Farringdon Street, E.C. A book on the subject is the "Half-Tone Process," by Verfasser (Iliffe).

COLLODION PAPER.—Will you kindly answer me the following questions in your JOURNAL? Whether C.C. matt prints toned in platinum bath are permanent or not? 2. I wash prints for half an hour between toning and fixing; is that right? 3. Also, how can I obtain sepia tones on same paper?—BLARNEY.

1. Yes, they will last for years if properly made. 2. Yes; all the better if the prints are transferred for a few minutes to a weak bath of soda carbonate after toning, and then washed for, say, a quarter of an hour. 3. Use a weaker platinum bath (more water), and arrest toning at an earlier stage.

FLASHLIGHT GROUP.—I have to take a group of about 150 or 200 performers in our opera-house here. It will be taken in the afternoon, but, owing to several of the windows being blocked out, there will be very little daylight available. I thought of using two flash lamps. What distance from group or stage

would you advise lamps placed? Would they have to be rear of camera? How much powder would you think necessary for each lamp?

With a large group like this the lamps should be placed at least twenty yards away to secure good modelling. They should also be well above the heads of the group—say, 20 ft. up, and, if possible, behind the camera. One light slightly to the left of the camera should be stronger than the other, which should be well to the right, or vice-versâ. Use about 2 oz. flash powder for main light, and 1 oz. for subsidiary light. Rapid plate and *f*/11.

PLATINUM RESIDUE.—I am informed that there are firms that take waste platinum prints, in order to obtain the platinum that is left unused in them. Would you kindly inform me whether you know the name of any firm that does so, as I have been unable to obtain the name of one?—A. B. C.

You will find the advertisements of several purchasers of photographic residues in our pages week by week.

LEARNING RETOUCHING.—What likelihood is there of a lady (never having had any photographic experience) learning "retouching" thoroughly? And, if there is no reason to prevent her, what course would you suggest? Briefly, I am prepared to go to a little trouble and expense if there is any chance of success. I am willing and anxious to learn, and am assiduous in anything I undertake. My husband's hobby is pictorial photography, chiefly portraiture, but neither he nor I have any knowledge whatever of retouching, and I wish to learn, if possible, not from any pecuniary motive, but simply as an adjunct to my husband's hobby. If you will give me your advice I shall be grateful.—A. E.

You should have no difficulty of learning retouching under instruction. If you are unable to obtain a teacher in your neighbourhood, you may put yourself under a well qualified instructor through the post; see our advertisement page 78. We cannot hold out much hope of your making satisfactory progress unaided.

PURCHASING SILVER.—As I require a quantity of metallic silver for experimental purposes, and as the second-hand metal purchased from jewellers, etc., varies so much in quality, while the price is always extremely high, would you kindly place favour me with the information—where, and in what quantities, the metal may be procured?—GEO. W. VENMORE.

You can buy pure silver metal from Merck, Jewry Street, London, E.C.

H. R. ROBERTSON.—Strictly speaking, your friend has no legal right to copy the photographs, but you need be under no apprehension as to using them in the limited and private way proposed. It would be a different matter if the slides were offered for sale.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

EDITED BY GEORGE E. BROWN, F.I.C.

THE forty-fifth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,612 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1906 will also consist of 25,000 copies.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1906 will be modified to make it more than ever the book of universal photographic reference. As in the past, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1906 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, the year's advances in theory and practice will be recorded, and wherever practicable new features of an informative nature will be added.

. IMPORTANT NOTICE.—Our publishers ask us to draw the attention of advertisers to the fact that the latest date for receiving orders and copy for advertisements in the "Almanac" is WEDNESDAY NEXT, OCTOBER 18.

EX CATHEDRA.

The British Journal Almanac, 1906.

The pages of the forthcoming "Almanac" are now in an advanced stage of preparation, and within the next two weeks will be completed for the press. We therefore ask contributors to place any MSS. they may have in preparation in our hands with as little delay as possible. The "Almanac" is booked to appear on December 1, and as the largeness of the edition makes it impossible for copy to be considered after October 18, it is hoped that we shall not be compelled to exclude articles or formulæ from the volume, not from a desire to do so, but from exigencies of time and the demand from our publishers and the public for prompt publication.

Advertising.

This is possibly one of the best opportunities the good business man has of showing his ability. To put himself and his productions in the most advantageous way before the greatest number of people is the aim of every man whose heart is in his business. At the same time, there is no way of frittering away money so quickly and to such little purpose as by misdirected advertisement. Circulars, newspaper paragraphs, and pages in bazaar programmes all have their uses; but the value varies according to local circumstances. We believe a good window display, attractively arranged and frequently changed, is of the utmost value in attracting business. We recall the case of a business in the home counties which the owner admits was largely made by the judicious use of an unusually extensive window display; but each display was changed regularly every week. Where the population is not a floating one, a business thoroughly established as the best studio in the district may do with a good deal less advertising or window show. In large towns it is necessary to keep one's work constantly displayed. Fresh people are continually coming and form their opinion on the work shown, and by comparison with other windows. One of the most effective methods of advertisement is the cultivation of a distinctive style of work. Some years ago a well-known and very artistic Scotsman commenced the production of very warm toned P.O.P. prints. They attracted customers, and very soon people got to say, directly a warm-toned print was shown them—"That's a portrait by so and so."

* * *

Preparing the Studio for the Winter.

With the first early signs of winter some difficulties may already have been experienced in preserving the tightness of the studio roof. During the summer months the putty dries and becomes brittle, cracks, and

in places leaves the glass, and, as a consequence, the water finds its way in. Of course, to remedy this evil the services of a glazier must be invoked; but a few hints as to how he should proceed may be useful.

Old-Fashioned Studio Roofs.

The most troublesome roofs to deal with are those constructed in the earlier days when it was erroneously considered that the more glass there was in the studio the shorter would be the exposure required. With the above idea the sash bars were frequently made so slight that they were scarcely strong enough to bear the weight of the glass they had to sustain without bending, and with a heavy wind they would give considerably. We have been in a studio of this description in a heavy gale and seen the roof bend in to an almost alarming extent. Under such conditions there need be little surprise that, after a hot summer the over dry and non-elastic putty should crack and separate from the glass. In such a case the first thing to do is to strengthen the sash bars, and render them rigid. This may be done by fixing inside and transversely a bar of T iron which is screwed to the sash bars; this by reason of the strength of the T-shaped bar will confer great rigidity. If the roof be large, two bars may be required. Having secured rigidity in the sash bars, we have a fair foundation to work upon. The old putty, wherever it is found to have cracked or separated from the glass should be hacked out and the parts painted, the paint being well worked in between the edges of the glass and the wood or iron as the case may be. When this is dry, or partially dry, new putty should be filled in, and the work receive a coat of good whitelead paint.

Maxims in Studio Repairs.

The putty used is of importance. It should be made of whiting and good linseed oil with a little whitelead, and not the putty of the oilshops. The addition of a little red-lead is sometimes recommended; it makes the putty dry quicker and harder; but it is a question if this is an advantage, inasmuch as it causes it, after a time, to become brittle and liable to crack if there happen to be any give in the sash bars. It is sometimes found—after the roof has been repaired—that water gets through it in places where it did not before, and often the workman is blamed for not doing his work properly. The fault is not, however, always his, for it may happen, owing to the slenderness of the sash bars, that his weight on the roof while finishing his work, causes the old putty, which it was not thought necessary to remove, to crack away from the glass, and so occasion fresh leakage. It has before now been recommended to tar the sash bars instead of painting them, and we have known cases where this has been done with good success. Tar does not become so brittle as paint, particularly bad paint. While the men are on the roof it is a good plan to get them to clean the glass thoroughly, for, as a rule, it is thickly coated with a yellow film of dirt from smoke. After the outside work has been completed it is well to give the inside of the roof sash bars a coat of paint. This will fill up any little points that may have escaped the outside treatment.

Heating the Studio.

After the studio roof has been made proof against rain, the next thing to be considered towards making the place comfortable for winter work is the heating arrangements. Some studios are painfully deficient in this respect, and a sitter, after having been shown from a none too warm dressing room into a cold and cheerless studio, is not by any means in the best

conditions for a pleasing portrait. If the studio is at a warm and genial temperature any little shabby appearance of the surroundings will probably escape attention, but if it be, as is too often the case, cold and cheerless, the total effect will be most depressing. Of course there are many ways of warming the studio. Undoubtedly the best is by means of hot-water pipes with the boiler outside the building. It is cleanly and economical, but somewhat costly to fit up. Yet if all the rooms are on one floor it is not unduly so, for one fire will suffice for all, and then this system will be found, on the whole, superior to any other. The drawbacks to this method of warming—and all systems have their drawbacks—are that the fire must be started some hour or two before the heat is necessary so as to get the water in circulation, and that the pipes are liable to be stopped, and possibly burst, by a hard frost. This may, however, be avoided by keeping a small fire going under the boiler during frosty weather. In a small hot-water installation gas may be employed as the fuel, and that is easily regulated.

Heating by Gas.

Gas as a means of heating is exceedingly convenient and easily under control. But it has its drawbacks. For example, if the stove has a flue to carry off the products of combustion to the outside, then much of the heat is lost, as, thus used, gas is not at all economical. Other gas stoves which do not require a flue, and yet give off no fumes, are unfortunately productive of very little heat. The most economical gas stoves are those in which the fumes from the burning gas escape in the apartment. The fumes are unpleasant and injurious to health if the stove is in an ill-ventilated apartment, but photographic studios, as a rule, cannot be classed as that, as the roof usually affords a fair ventilation, and if a vessel of water be placed on the stove, or beneath it, much of the unpleasant vapour will be absorbed. There are many forms of these stoves on the market at a moderate price, whilst most of the gas companies will let the stoves on hire at quite a nominal charge, and some even go so far as to fit them free of cost. Last winter we saw in a good-sized studio a so-called "Chancel" stove, supplied, if we mistake not, by Fletcher and Co. It is a flat stove and lies near the floor, and gives off a good heat with a moderate consumption of gas. Of course, all the products of combustion remain in the room, but there was a tin tray of water underneath it that absorbed a large proportion of them, so that the atmosphere of the place was not unduly unpleasant.

Pipe Stoves.

A very general way of heating the studio is by a pipe stove, an economical method particularly if there is a good length of pipe within the room. The best form of stove is one of the slow-combustion type. With these almost any fuel may be employed, even the cinders from ordinary grates. The rate of combustion is conveniently regulated by means of dampers. The stoves require but little attention; if they are filled up in the morning and the dampers not opened too widely, they will keep a studio at a comfortable temperature throughout the day without the addition of more fuel. If made up in the evening and the dampers nearly closed, they will keep alight all night. They are to be had of all sizes and all prices. Some of those encased with tiles are exceedingly ornamental, and not very costly. Small, plain iron ones are to be had for about a guinea, and these will suit admirably for a small studio. There are one or two disadvantages attending these stoves. One is that the combustion is so perfect that the fuel is con-

sumed to a fine ash, and when it is cleared out a good deal of dust is created. Another is that the insurance companies have an objection to pipe stoves, and will sometimes increase the premium where they are in use. In no case should a pipe stove be fitted without giving the insurance company notice, or the policy may be invalidated.

* * *

Blinds and Skylights.

The condition of blinds and glass in the studio roof requires attention about this time of year. Possibly the inner side of the glass has been covered with mineral paper through the summer, and this will have become more or less yellowed in the continuous strong light. Its light-stopping power will be much too great for even bright October days, and it should be removed entirely and at once, and the glass thoroughly cleaned both inside and out. If direct sunlight enters in any particular places new pieces of paper may be affixed by their edges, and will serve to diffuse the direct rays without lessening unduly the actinic power. Not only does the sunshine of July and August affect the temporary diffusing media, but it lessens the efficiency of blinds or curtains, bleaching to some extent dark blinds, and, in combination with dust, and rain leakages, darkening any light blinds which may be employed. Prompt attention to all these matters will not only make work much simpler and more certain, but will give the studio a bright and fresh appearance. In any event, roller blinds must be taken down and thoroughly wiped with a damp cloth, and, if the material is rotted, as is often the case, new blinds should be fitted. White blinds may be washed unless very badly stained.

* * *

Dark-Room Safe Lights.

If the developing-room is illuminated by daylight filtered through some orange or ruby material, the summer light will probably have lessened the efficiency of this medium. Particularly will this be the case if the medium employed is paper or one of the stained fabrics, though it must not be too readily assumed that continued strong light has no effect on coloured glass. We are often surprised to note the dodges resorted to by workers to enable them to develop with what they know to be a more or less unsafe light. As the cost of renewing the materials is so very slight, this can only be to save the trouble of doing the work. If the least doubt is entertained, the filtering media should be renewed at once and the new light carefully tested. This can be done by exposing one half of a plate of the brand in use for say two minutes, placing the dark slide in the spot usually occupied by the dish when developing. The slide must be loaded in darkness, and the plate developed for five minutes with a normal developer, keeping the dish covered the whole time. If, on fixation, no difference can be seen between the two halves of the plate, the light may be regarded as safe. It must be observed that, though a light may be perfectly safe when tested in this way, if the plates are held repeatedly and for unduly long periods close against the window, fogging may ensue with the safest of "safe lights." A plate may remain unfogged with the light two feet away; but may be very readily fogged when held within two inches, receiving as it would 144 times as much light. It is assumed that the dish will always be covered during development, and the time of the test exposure, viz., two minutes, is long enough to allow for one or two brief examinations for density towards the end of development. Assuming daylight to be the illuminant, the test should be made about noon on a bright day, so that the maximum light is known to be safe.

PRINTING PROCESSES.

XIV.—BROMIDE PAPER.

In the last article the question of suiting the exposure to the developer was considered; the production of good black tones on bromide papers depending on correct exposure, combined with normal development. If the correct exposure necessary to allow the light to penetrate the densest parts of the negative is departed from, the constitution of the developer has to be altered to compensate for this difference, and the colour of the developed image becomes altered also.

Of the modern developers for bromide papers amidol probably stands highest in favour. This is due, not only to the rich black colour obtainable with correct exposure, but also to the simplicity of the formula employed and the ease with which it is made up. No free alkali is necessary with this developer, and the only disadvantage in its use is that it loses its developing power entirely if kept for long as a stock solution. This developer, therefore, should be made up fresh for each batch of prints, and the most simple method of quickly preparing it is to keep a stock solution of sulphite of soda, and add the dry amidol as required.

A convenient form of keeping the sulphite of soda is in a 10 per cent. solution. Sufficient water is added to two ounces of sulphite to make twenty ounces, and twenty grains of potassium bromide added. To each ounce of this stock solution five grains of dry amidol are added just before use, and the developer is then diluted with an equal bulk of water. The amidol will dissolve readily, but care should be taken that no particles remain in the solution or black spots will be caused on the prints. Filtering the developer will obviate this.

If the stock solution of sulphite of soda is objected to, an alternative formula giving excellent results is:—

Water	20 oz.
Sulphite of soda	650 grs.
Potassium bromide	10 grs.
Amidol	50 grs.

This should be mixed in the order given and used within twenty-four hours.

The restraining effect of potassium bromide is not very marked with amidol developer; and its action appears to be confined to keeping the whites pure. The best restrainer for use with this developer—when one is needed,—will be found to be citric acid. A few drops of a 10 per cent. solution has a very marked restraining action.

Rodinal, in the concentrated form as purchased, can be regarded as an even simpler form of developer than amidol. Water and potassium bromide are the only additions necessary to make a reliable developer for bromide prints; but in many workers' hands it does not give such fine blacks as amidol. The correct procedure with rodinal is to develop with a dilute developer consisting of rodinal, 10 minims; potassium bromide 10 per cent., 3 drops; water, 3 ounces, or any larger quantity in the same proportions. If the paper has been correctly exposed, a weak, grey image will appear in about a minute. The developer should then be poured off and rodinal 25 minims, potassium bromide 5 minims added to it and well mixed. This is poured back on the print and development completed. A good black tone should result.

Both metol and hydroquinone have qualities of their own that commend them to the bromide-paper worker, notably cleanliness of working and the number of times they can be used before exhausted. Metol, however, has, unfortunately, an affinity for the cuticle of some workers, and its well-known effects debars its use. It is, neverthe-

less, used extensively by more than one trade enlarger, and professional bromide printers who employ it find it very rapid in action and certain in results. The rapidity of metol is somewhat against its universal adoption, although by following a certain procedure, as with rodinal, fine black tones are obtainable. It is in combination with the slow-acting hydroquinone that we get an almost ideal developer. Used either as a one, two, or three solution developer, metol-hydroquinone acts equally well. For general purposes the following one-solution formula will be found to give greatest satisfaction for correctly exposed bromide prints:—

Metol	16 grs.
Hydroquinone	60 grs.
Sulphite of soda	1½ oz.
Carbonate of soda	1½ oz.
10 per cent. potassium bromide solution	40 min.
Water	40 oz.

Ortol has also considerable claims for attention as a satisfactory developer for bromides, and unlike amidol, it is slow-acting. A certain amount of time is therefore necessary for the image to gain full strength, especially if the developer is used in a dilute form. It keeps well in solution, does not stain, and can be used several times before exhausted. A good formula is:—

A.—Water	20 oz.
Metabisulphite of soda.....	150 grs.
Ortol	½ oz.
B.—Water	20 oz.
Carbonate of soda	1 oz.

Equal parts of each are used for obtaining a good black colour, but it will be found that with increased exposure and the addition of potassium bromide pleasing warm tones are easily secured with this developer.

Edinol and adurol also lend themselves to the production of warm tones on bromide paper by increased exposure combined with dilute developer well restrained with bromide.

For the production of the finest warm tones on bromide paper by development one must employ pyrogallic acid as the agent. It is a mistake to imagine that "pyro" is more likely to produce stains than any other developer used with the same amount of sulphite. Used either with ammonia, soda, or potash as the accelerator, pyro will be found to prove a very good developer for bromide paper. The following formula will prove reliable:—

A.—Pyrogallic acid	½ oz.
Sulphite of soda.....	3 oz.
Citric acid	1 dr.
Ammonium bromide.....	1 dr.
Water up to	10 oz.

B.—Carbonate of potash	½ oz.
Sulphite of soda.....	½ oz.
Water up to	10 oz.

With normal exposure take 30 minims of A and 80 minims of B, and add one ounce of water. This will give a warm black image. Double the exposure, double the quantity of water, and add 10 minims of a 10 per cent. solution of potassium bromide and an agreeable warm tone is produced. Increase of exposure, coupled with further dilution of the developer and additions of bromide will, with this formula, give a range of colours from black to red.

WARM-TONED BROMIDE ENLARGEMENTS.

HAVING noted from time to time the inquiries for a reliable method of toning bromide prints, I beg to submit the enclosed method to readers of the B.J.P. I may say that the method here described has enabled me to considerably increase my business and to obtain a price half-way between that of ordinary bromides and carbon, and I find they give absolute satisfaction. I have had a print in full sunshine for the last two summers and it shows no sign of any change whatever up to now, which, I think, a very severe test.

First, select a good bromide paper—the ordinary smooth-surfaced variety is best, known to possess a heavy coating of emulsion. Make the enlargements in the ordinary way, taking care that there is a fair amount of contrast. The print should be very thoroughly soaked in alum, or formaline, or, better still, both, as the subsequent toning operations tend to blister and soften the film.

When the enlargement has been very thoroughly washed, it is placed in the following bleaching solution (which may be poured back into the bottle and used over and over again) until all trace of blackness has disappeared, and only a faint image remains visible. This takes from a few seconds to two minutes.

No. 1.—Potassium ferricyanide	1 ounce.
Ammonium bromide	1 drachm.
Water	20 ounces.

Rinse quickly in two changes of water and transfer to the following, which can only be used for one batch of prints and should then be thrown away.

No. 2.—Sodium sulphid. (sat. sol.)	1 drachm.
Water	5 ounces.

It is sometimes necessary to use this rather stronger, but the weaker it is the less chance there is of blistering. In this solution the print will gradually regain full vigour, and, if in the first instance at all too dark, may be taken out when the correct intensity is reached.

The prints will now have assumed a rich sepia-brown tone, which has not affected the original permanence, or in any way degraded the whites.

They should be washed for at least fifteen minutes and hung up to dry.

When quite dry, any surface may be produced by first soaking and then squeegeeing on to any of the following, which must, of course, be absolutely clean and prepared with French chalk, or any other preparation to prevent sticking, in the same way as for P.O.P. Rough ground glass can be used for broad effects; opal for medium surface, and fine ground glass, as used for focussing screens, for semi-matt surface. Ordinary temporary support, as used for carbon prints, well waxed, produces a surface similar to the ordinary carbon print. If a highly glossy surface is desired, the glossy paper may be used and squeegeed on to polished glass in the ordinary way. It is advisable to back prints while on the support, and mount by gluing the edges only. Enlargements treated in this way have the richness and depth of carbon prints, and, as far as exhaustive tests can prove, are practically permanent. W. SHENTON.

THE WEEK IN HISTORY.

The Ammonia Process of Emulsion-making.

It is just a year over the quarter of a century since the Monckhoven ammonia process of ripening an emulsion was published and came into use. Dr. Monckhoven's first paper appeared in the *BRITISH JOURNAL OF PHOTOGRAPHY* for October 17, and though it was not by any means the first communication on the use of ammonia in emulsions, credit is due to Monckhoven for his explanation of how the increase in the sensitiveness of the emulsion came about. Those who are interested in the literature of this single item in photographic progress should turn up a letter to the *BRITISH JOURNAL* from Mr. E. J. Wall on January 13 of the present year. Monckhoven added the ammonia at the last. "Its effect," he wrote, "is to render the ammonia ready to be used in a few minutes; or, if great sensitiveness be required, it can be obtained in a few hours instead of days, and thus decomposition of the gelatine is avoided."

This process is a combination of those of Mr. Bennett and Messrs. Wratten and Wainwright with this difference—that I add the ammonia in order to have the emulsion ready to work in a few hours instead of days."

The Invention of Pigment Printing.

The letter of Mr. Walter S. Corder passed on to me by the Editors, and printed this week on another page, raises certain points with which I will gladly deal, though I am not at all sure that I can add anything to what was written in previously referring to Ponton's work in the "Week in History" for May 12. Mr. Corder's queries may be collected under the title "The Invention of Pigment Printing" at the head of this paragraph, because without the fact of insolubilisation of gelatine, etc., by the bichromate in light there would be no printing in pigments any more than there would be photogravure and the other photo-mechanical processes. Mr. Corder asks in what manner the credit for the early work in these processes should be divided between Ponton, Talbot, and Poitevin. To answer his question first in a word or two, the evidence seems to be that:—

Ponton first applied the known fact of the sensitiveness of bichromates *plus* organic matter to light in the delineation of objects, i.e., copying engravings by contact.

Talbot was the first to observe the insolubility of gelatine produced on exposure to light with bichromate.

Poitevin applied this fact to preparing photographic pigment prints, taking advantage of the insoluble gelatine to fix the pigment.

Thus bichromates in photography are due to Ponton, photo-mechanical bichromate processes to Talbot, and pigment printing to Poitevin.

I cannot find that Ponton regarded his bichromate process as involving anything more than the production of an image produced by light from the substance. Certainly had he done so, Hunt in his "Researches in Light" (1854) would have added a note of the fact to his description of Ponton's work. He is the more certain to have done this, as he himself worked out a modification of Ponton's crude process which he named "chromatype." But beyond some observations Becquerel published in the "Comptes Rendus" for 1840, I cannot find any further perfection of Ponton's work until Talbot patented his photo-mechanical process in 1852. I shall refer to this process in the "Week in History" for October 27, so that perhaps Mr. Corder will allow me to leave it until then. Poitevin's English patent in which he announced a photo-mechanical process, which was practically collotype, appeared in 1855. It contains also the description of the pigment print which Talbot in his aims at a mechanical reproduction had overlooked. His invention stirred up interest in pigment processes, and led to the offer in 1856 of a prize by the Duc du Luynes for methods of making permanent photographic prints. One participator in the awards was Mr. Poncey, with a process substantially that of the present gum-bichromate.

HISTORICUS.

ON THE ORTHOCHROMATISM OF PLATES BY BATHING.

In the course of an article on bathed gelatine plates in "Photographische Korrespondenz," Dr. E. König reviews the present practice of orthochromatising ready-prepared plates. Bathed plates, in the case of dyes which strongly stain gelatine, are more strongly dyed on the surface than underneath. That fact, however, is not an explanation of the greater sensitiveness of the bathed plate, inasmuch as plates which are bathed until the dye penetrates completely through the film of emulsion show the same sensitiveness as those bathed for only a few minutes. Also plates containing pinachrom in the emulsion give, on being bathed in a pinachrom solution, the same sensitiveness as ordinary plates of the same mother emulsion treated in the same dye bath.

Sensitisers With and Without Ammonia.

It is customary to add ammonia to many dye baths, an addition which is absolutely necessary with many dyes, such as Wollschwarz and Benzolnitrolbraun, in order to obtain a notable degree of sensitiveness. Without ammonia, only those basic dyes are used, e.g., those of the acridine series, which are precipitated by ammonia.

Mr. Kieser has recently examined the sensitising properties of a new series of dyes produced by the action of cyanides of the halogens on pyridine and aniline. He found that in the case of these dyes the sensitising power is greatly raised by ammonia. As is already mentioned in the instructions for the use of the Höchst orthochrom and pinachrom, the ammonia can be left out of the

sensitiser. Many plates are not fitted for sensitising with the isocyanines, as they show fog thereby sooner or later; but this fog, as a large number of experiments has shown, occurs only in the case of sensitising baths which contain ammonia. Sensitised in neutral dye-baths, these same plates will keep for months in perfect condition. The sensitiveness of plates thus sensitised with orthochrom or pinachrom in neutral solution proves, in practical three-colour work to be about equal to that of the ammonia-sensitised plates, when both are exposed behind the green screen, and about four-fifths that of the ammonia plate behind the red screen. The following formula is recommended for orthochrom or pinachrom:—

The plate is bathed in the dark for two or three minutes in—
 Water 200 ccs.
 Dye solution 1:1000 3 to 4 ccs.

Washed for two minutes and dried. Specially rapid drying in a forced draught is not necessary. The plates work perfectly clearly when dried spontaneously in the air. A further advantage of the non-ammoniacal sensitiser is that ordinary tap-water can be used for the dilution of the dye solution. With ammonia in the bath, carbonate of lime is precipitated from the calcium bicarbonate in solution, and this action makes itself evident in markings on the film. Even when distilled water is used for the ammoniated bath, a precipitate of carbonate of lime is often produced when the plates are washed in tap-water.

How Washing Benefits the Bathed Plate.

It is often stated that the washing of bathed plates is useful by removing the excess of dye, and that the latter is the more easily washed out, the greater the solubility of the colouring matter. But this general rule does not hold good—at any rate, not for the cyanine dyes. There is little probability of producing dyes of such strong basic character as those of cyanine, which will be removable from the gelatine film by simple washing. To refer to facts, the experiments showed that equivalent solutions of nitrate sulphate, chloride, bromide, and iodide of orthochrom, i.e., substances of very different solubility in water, when employed to dye gelatine plates to the same depth, could none of them be totally removed by washing. Moreover, plates dyed in the very easily soluble sulphate or chloride was left just as strongly stained after five minutes washing as those immersed in the difficultly soluble iodide. Their behaviour in this respect does not stand alone, for other very soluble basic dyes, such as methyl violet, are not removable from water by simple washing in water.

The indisputably favourable effect of washing on bathed plates consists only in this: that the adhering dye which easily dries on the film in streaks and patches, is removed. This takes place on merely rinsing the plate, but the presence of alcohol in the dye-bath may render the action uneven. Washing should therefore be done only until the so-called "greasy" appearance of the surface of the plate disappears. It is perhaps not generally known that these "grease markings" occur very lightly, or not at all, if the dye is dissolved in methyl alcohol in place of the ordinary spirit (ethyl alcohol).

Ammonia Substitutes in the Sensitising Bath.

But it is possible to employ an alkali with a less injurious effect than ammonia in the sensitising bath. A solution of pinachrom containing 1 per cent. of potassium carbonate was found to give greater red-sensitiveness than a pure aqueous solution.

It is also worth while to note that a solution of cyanine or isocyanine prepared in water by means of completely neutral ammonium salts, such as the chloride or sulphate, is almost completely decolorised, but the colour returns in the presence of an alkali. If plates are bathed in a pinachrom solution to which 1 per cent. of ammonium chloride is added, somewhat greater colour-sensitiveness is obtained than with a pure aqueous solution. Sodium chloride acts in a similar way, but ammonium sulphate and sodium sulphate exhibit no sign of this action.

The user of sensitising baths will be well advised to add nothing to the solution, and to sensitise his plates on the lines suggested above. The action of ammonia is noteworthy in the case of Schleussner plates, which, on being sensitised in ammonia-pinachrom baths, fog, as a rule, but give excellent results, and keep for months when sensitised without ammonia. The new "special rapid plate" is specially suitable.

Cyanine and Cyanine.

Before closing these remarks on orthochromatic practice, a few words may be said as to cyanine itself. By this dye is usually understood the substance, lepidin-chinolin-amyli-cyanine-iodide, discovered by Williams and examined by A. W. Hofmann. Although this compound is perhaps the most unsuitable of all lepidin cyanines for photographic purposes, it appears to be almost always used. Williams' cyanine is insoluble in water, and very easily soluble in alcohol, and hence it is not very easy to obtain it in a perfectly pure state, and to separate it from the resinous and flocculent bodies occurring in the production of the cyanine. In fact, commercial cyanine is very often highly impure. For photographic purposes the lepidin-chinoline-ethyl-cyanine-iodide, which is less soluble in alcohol and more soluble in water, is far more suitable than the old Williams product.

As a colour-sensitiser of plates cyanine is in the bad books of emulsion makers. Plates sensitised with it show fog and markings, and the sensitiveness is reduced to one-fifth or one-tenth. The fog and markings cannot be laid at the doors of the slight solubility of the iodide salt of cyanine, since the easily soluble nitrate and chloride exhibit the same defects. Probably the depression of sensitiveness found by different observers is due to impurities in the dye. Carefully prepared dye (amyli cyanine) with or without addition of ammonia, produces plates which, according to the writer's tests in daylight without a filter, as well as by sensitometric measurements, are not appreciably less sensitive than the unbathed plates. Also, plates produced for some years by the Höchst Works with ethyl-cyanine exhibit greater sensitiveness than those made with amyli-cyanine. Compared with pinachrom, the sensitiveness of the ethyl-cyanine plates, as seen in spectrum exposures, reaches further into the red. The sensitiveness of the ethyl-cyanine plate, however, behind the red filter is somewhat less than that of the pinachrom plate. A spectrogram made by aid of a given dye gives by itself no useful indication of the value of the colouring matter for photographic purposes.

LETTERS TO A MIDDLE-CLASS PROFESSIONAL.

III.

DEAR J.,—In my last letter to you (see B.J.P. for August 18) I discussed the colour of mount advisable for your different needs, intimating that in the future I hoped to discuss other little matters which go to make a successful and pleasing mount. This is my fulfilment, and I shall treat briefly of outside size of board, thickness of board, bevels, position of space to surround print, type of border to enclose print, position for name and address.

All these may seem to be of no moment, and be left to the mount manufacturer, but, personally, I think that they should receive your best attention, for mounts, as a whole, are very similar, and only in small matters can individuality be shown. I think, and would mention right here, that half a day spent in designing and making full working drawings for mounts is time well spent, and that the man who takes a pride in every portion of his work should invariably provide the mount maker with these full instructions rather than accept the conventional and often badly-designed and proportioned mounts that will otherwise be supplied.

I trust that if I seem too positive and somewhat pedantic you will forgive me. Doubtless all my suggestions will not commend themselves to you, for taste is a personal factor and differs considerably. That which may be bad taste to some appears good to others, and vice versa; but in this letter I wish to point out the lines on which a mount should be made, so that it will suit the greatest number of people and prints.

The outside size of mount has, of recent years, tended to get larger and larger. Most of us can remember the time when any one size of mount was used for all cabinets, and all cabinets were not square. The mount was usually only one-eighth bigger than the print on three sides, with larger piece at bottom for name and address. In those days one only had to say 10,000 of so-and-so at 25s. a 1,000 and the matter was settled. The change is, from artistic reasons, excellent—from a monetary standpoint, perhaps, not so commendable; though, even if we must stock three or four colours in mounts, and square, cab, panel, oval, court oval, and circle shapes in most

sizes, our work is certainly enhanced, and the numerous shapes give greater freedom in composition. The mount order is certainly more complicated, and, as I want to drive into you, should receive your concentrated attention.

The small close-up mount may be left out of our calculations, and we will discuss the size and proportions of board, not forgetting that these depend greatly on individual circumstances, though, as a rule, a small board is nowadays poor economy. The public want all they can get for their money, and these large mounts enhance the importance of the print. Therefore I say spend a little more on your mount order and get good-sized mounts, they look good value, and, if the colour of board is well chosen, the print is improved and looks "swell."

The square cabinet is still, and deservedly, a favourite shape. The boards for this size vary, but 10 by 8 has been a favourite size; it suffers, however, in common with other shapes, by being too square. The newer 10 by 7 is preferable. This size, however, now mounts are getting so large, is just a trifle skimpy, and 11 by 8 is better. This size is a standard one, and cuts economically; 12 by 10 is a trifle large and square, though the usual size for paper mounts.

Taking things all round, the 11 by 8 is advisable. The longer proportions are more effective than the 10 by 8, and, as I hope to show you, a long mount is extremely useful. It has long been the custom of mount manufacturers to vary the size of board for the panel, oval, and circular shapes, making them much smaller than the square cabinet shape. This I think a mistake, for these sizes, to begin with, are smaller in area than the old-fashioned square, and when placed on a smaller board look insignificant compared with these, though the prints cost us as much to produce. The sale for these sizes is thus curtailed, and the primary aim of saving money

on the mounts almost defeated. Anyhow, the saving is only a few shillings a thousand, which the superior appearance of the larger mounts should repay. Moreover, by choosing a regular outside size for all cabinets, with suitable placing of the print, not only do the various shapes look of equal value, but many other things are simplified.

As you may not be quite "au fait" with the sizes of mount that cut most economically from makers' board, the following measurements may help you; there are others, but these are about the proportions for economy and effectiveness. The larger sizes do not require so much border as the cabinets. The carte, also, is somewhat small, this not at present being a selling size.

Size in inches:—For carte, $4\frac{1}{2}$ by 8 (this is a long, handsome shape); for whole-plate (Imperial), 14 by 11; for panel, 16 by $10\frac{1}{2}$; for 12 by 10, also 10 in. circle and 12 in. oval, 18 by $13\frac{3}{8}$. To recapitulate a remark made in my last, as it is important, "it is advisable to order a set of mounts in one lot, as you are then sure of getting all mounts of identical material and colour. This is of the utmost importance for dressing show-cases, as nothing looks worse than mounts that have gone off to various tints."

The thickness of board is not of so great importance as the size, though it is usual to vary the thickness according to the size. Until recently the thicker the mount the more appreciated it would be, ten and twelve sheet being generally used. Since the introduction of the flimsy mounts opinion tends more towards boards of thinner substance, say eight-sheet. A nearer approximation to the paper mounts, popular but difficult to mount on, is the six-sheet board. This is just thick enough for wet mounting without cockling, yet it feels and looks delicate, and is preferred by many patrons to the paper.

But I must break off at this point and conclude my letter in next week's JOURNAL. STUDIOSUS.

DISTORTION WITH THE FOCAL-PLANE SHUTTER.

The occurrence of distortion in the photography of rapidly moving objects by means of the focal-plane shutter has frequently been dis-

our issues of January 20 and 27, in which attention was drawn to the right and wrong ways of working a focal-plane shutter when

Fig. 1.

cussed and disputed, and contrary opinions expressed in regard to it. The question was touched on in two articles on the focal-plane shutter in

photographing objects moving in various directions. A general rule for practice is to hold the camera so that the line of movement of the

shutter is parallel to that of the object, not at right angles to it. Our own opinion is that, with precaution in regard to this point, it is difficult to obtain distorted photographs of objects, even in the most rapid motion. The subject is discussed in two recent articles by German writers, which we may present here, in a slightly abridged form, in further reference to the matter. Our first author is Herr Emil Bose, in the "Physikalische Zeitschrift."

It is pointed out, as regards the speed of a shutter, that if a narrow slit moves over, say, 1-20th of the width or height of a plate in 1-1000th second, the actual speed for the whole plate is twenty times this period, or 1-50th of a second. Hence any object which moves appreciably in this time may become distorted as photographed on the plate. Many so-called instantaneous subjects do not move rapidly enough to show this distortion, but others, such as rapidly moving trains, may exhibit the distortion most plainly. An example is the

Fig. 2.

Fig. 3

blurred photograph of a motor coach on the Marienfeld-Zossen line. The angling of the conducting masts on the roof, compared with the upright telegraph poles, shows that a period of time elapsed between the exposure of the top and the bottom of the masts. The car, moving about 200 kilometers per hour, this time would correspond to a movement of the car of .55 metres; the height of the mast being three metres. From this it follows that the interval between exposure of the top and the bottom of the mast is .045 seconds. Although the whole car, which occupies about one-half the height of the image, was taken in 1-50th of a second, its great rate of movement shows the step by step character of the exposure, the car appearing to lean forward in the direction of motion.

A more striking example is seen in Fig 2, a photograph of a motor car at full speed in the Gordon-Bennett race. Here there is no mistaking the shifting of the various horizontal planes, nor the tilting of the front of the motor, which should be at right angles to the frame. One may reckon that the slit was .09 seconds in passing over the whole

plate, the speed of the motor can be taken as 150 kilometres per hour.

In order to show the distortion which occurs when rotating bodies are photographed with a focal-plane shutter, the following diagrams have been made (Fig. 3). They show the visible distortion of equidistant spokes for four different speeds of revolution. During the time occupied by an infinitely thin slit in travelling the diameter of the wheel, the latter made revolutions as follows:—*a*, 0; *b*, 1-10; *c*, 2-10; *d*, 4-10. It is seen that the spokes close up together as the speed of rotation is increased, despite the unsharpness of the spokes in the upper part of the wheels, where the movement is most rapid. This phenomenon can be seen in the photograph on the left-hand side of the wheel.*

It remains to say how this chief defect of the slit shutter can be avoided. The solution of the difficulty is simple, and by no means novel. The shutter is placed in the narrowest portion of the optical

Fig. 4.

system, *i.e.*, in or near the lens or diaphragm. If the full aperture of the lens be opened for exactly the time which the slit would take to traverse its own width, the whole exposure is obtained at one operation, and we have—to return to our previous example—a true exposure of 1-1000th second, in comparison with the instance already quoted, in which the exposure of the whole was 1-50th second, and of the strips 1-1000th second.

It will thus be easily understood within what limits a shutter can be worked without giving distorted pictures. Whether there are shutters which can be worked at a speed equal to that of the focal-plane is a matter apart from the present considerations.

The second paper is by U. Behn and W. Heuse, in the "Zeitschrift für Wissenschaftliche Photographie." With a view of examining the distortion which occurs when photographing a horizontally moving object with a vertical slit (Figs. 1 and 2) they proceed as follows in order to obtain by photography distortion of the kind produced by

* We fear the reproduction does not show it.—Eds. B.J.P.

calculation in Fig. 3. The test object is a disc of card (Fig. 4) about 50 cm. (20 in.) in diameter, across one diameter of which a strip of white card, 1 cm. ($\frac{1}{2}$ inch) is fastened. The disc is rotated on its centre by a motor driving it at a constant speed. A 10 by 18 cm. camera is provided with a lens of 210 mm. ($8\frac{1}{2}$ inches) focus, the image of the white band being 10 cm. (4 inches) on the focussing screen, so that the slit was used over almost its whole effective portion. The number of revolutions per second could be varied between two and eight. The speed of the slit (9 mm. wide) was about 50 cm. per second.

On rotating the slit the vertical component of movement of the point A (Fig. 4) on the band near the edge of the screen is represented in diagram (Fig. 5) by a sinus curve *a*. The movements of the points B, C, D, E, and F, are shown by similar curves of smaller amplitude. Representing the movement of the slit in the same diagram we ob-

on the breadth of the slit. Fig. 7 is a specimen. Such curves, in which the slit running oppositely to both halves of the strip and meets it twice, are frequently obtained. As shown in Fig. 5, the conditions are favourable to its occurrence since the moment of emergence of the slit, can be varied within extremely wide limits.

The intersections of the lines, *gr* and *st*, with the sinus curve give a figure of special interest. In this case the slit meets the opposing half of the strip as it passes through the horizontal position, i.e., at the moment of greatest speed in the vertical direction. The image is practically without distortion. When moving with the slit the arm, the outer end of which is met three times, at *a*, *b*, and *c*, is subjected to a hammer-shaped distortion (Fig. 8b). Fig. 8 shows the image obtained by construction. This thrice-repeated coincidence and the image resulting from it can only be obtained when the speed of the

Fig. 5.

Fig. 6.

Fig. 7.

Fig. 8.

tain, in the case of constant speed and infinitely narrow slit, a straight line, the position of which is fixed by (1) The moment of emergence upon the field of vision, i.e., by the section on the axis of the co-ordinates; and (2) By the speed of the slit, i.e., by the angle this line makes with the axis. In the case of an accelerating movement this line is bent up, more so as the breadth of the slit is represented by a correspondingly broad band in the drawing. The points where this band intersects the sinus curve represent the coincidence of the slit with corresponding points of the image of the band. By means of these points the distorted image can be built up.

In Fig. 5 the lines *mn* and *op* represent the front and broader edge of the slit respectively. By constructing a distorted image from the intersections of these lines with the sinus curves, we obtain the curves *mnw* and *opv* in Fig. 6. The area enclosed by these two curves depends

slit is somewhat smaller than the maximum value of the vertical component of the movement of A. Only in this case is it possible for the slit to overtake the point, then to be overtaken by it, and finally as the vertical component of the slit again falls off to meet it once more.

Intermediate between these two characteristic types of distortion are figures 9 and 10. In the case of both, the arm moving with the slit is first met at its outer end, and the formation of the whole image then commences from the other end. Whilst, however, in Fig. 9 the parts lying near the periphery of the moving arm first overtake the slit and are then overtaken by it, these points in Fig. 10 occur only within the area of the slit and remain behind without having overtaken it. For this reason in Fig. 9 there is a luminous segment with a dark nucleus *kkk*, such as occurs also in Fig. 8b, this dark nucleus being missing in Fig. 10. These characteristics are obtained

analytically by taking the speeds of the rotating strip of the slit as constant according to the formula:—

$$r \sin \phi = a \phi + b,$$

where a is the ratio of the two speeds and b the phase-constant. The distortions of Figs. 7 to 9 can be very prettily demonstrated by running the image of a slit over a large rotating screen with a band across its diameter.

In considering how this defect of the focal-plane shutter is to be avoided, it is well to consider the various subjects in two groups. Either it is desired to obtain a representation of a moving object, say for photogrammetric purposes, in which absence of distortion is the first consideration, even at the expense of sharpness, *masumi*, as

sary. These rules have not been followed in at any rate the first of exposures shown in Figs. 1 and 2, and, therefore, the defects of the shutter are made out worse than they need be: a slight compression of the image of the car, when using a horizontally running slit, would scarcely be noticeable.

In conclusion, a further point in reference to the focal-plane shutter must be mentioned. The exposure reproduced above permits of an estimation of the total time of exposure, and also of the time of exposure of the separate parts.

If the slit ran with uniform speed, the time of exposure for separate parts of the image would be the same. But it can be calculated from Figs. 7 to 10 that this is not the case.

Fig. 8B.

Fig. 9

Fig. 10.

Fig. 11.

Fig. 12.

distortion will vitiate any measurement of the prints; or a negative is required of the utmost sharpness. The first consideration is generally that of scientific photography; the second that in commercial and amateur work.

In the first case, the suggestion of Herr Bose may be taken and the shutter placed in the diaphragm slot, but all the advantages of a shutter close to the plate are immediately lost, chiefly the employment of the full aperture of the lens. In the second case the slit travels close to the plate, and it should then be made a rule to have the slit moving in the direction of the quickest movement of the subject. Also the blind should be driven at its highest speed, *i.e.*, with the slit fully wound, and the slit narrowed as may be neces-

The following proved to be a more informative method of work:—An object hanging at rest vertically was photographed with a camera, moving at a constant speed on a vertical axis. In practice, silvered glass balls strung on a thread were strongly lighted whilst hanging in the vertical position. The camera, with its moment of inertia purposely increased, was rotated on a vertical axis with such slight friction that its speed did not fall off as much as 1 per cent. during a whole revolution, as it moved only through about 30 degrees during the exposure the error from variation of speed was less than 1 per cent. On photographing the series of luminous points in silvered balls, a curved series of short lines was obtained on the plate, as shown in Figs. 11 and 12. In the first is seen the images of luminous points,

photographed with the camera at rest. A slight alteration in the speed of the slit during the movement can be detected in two ways. First, the length of the short lines is different, and the curve of the whole series is more or less inclined, the band thus undergoing

compression. Both phenomena prove that in this case the speed of the slit has increased during the total course, in consequence of the mass and inertia of the roller and in spite of the falling-off in tension of the actuating spring.

THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

FOURTH NOTICE.

The Professional and Trade Sections.

THE display of general professional work in the South Room is one of the most interesting which has been made since this section of the exhibition was given a room to itself. In noticing the various pictures we frankly recognise that there are different styles and classes of work, and our remarks, whether critical or appreciative, are based on this. No greater mistake can be made from a commercial point of view than to offer the public something for which it is not ready, and if a professional finds P.O.P. or bromide preferred to carbon by his clients it is obviously unfair to him to find fault with his display on account of the method of printing employed. The aim of the professional section is to afford bread-and-butter photographers an opportunity of displaying bread-and-butter photography. At the same time, what is done should be well done, and our criticisms are on the way methods have been employed rather than on the methods themselves.

Taking the exhibits in the order given in the catalogue, we come to the display of Miss Stephanie Maud, of 16, Brook Street, Hanover Square, W. This lady shows some originality of idea in her posing and arrangement of accessories. An interesting portrait of a child opening a cupboard door, and peeping in shows that Miss Maud has some original, or at any rate individual, accessories to work with. It is of course open to the objection that the face is not seen, but it is sometimes possible to give an excellent likeness without showing the face. There is character about a well-caught pose. From a business point of view perhaps the experiment is risky. A black platinotype of a girl sitting reading a letter is pleasingly arranged, and delicate in production.

From his studio at 4, Onslow Place, South Kensington, S.W., Mr. W. H. Harrison sends a number of capital portraits, all of ladies or children, and we believe this photographer makes a specialty of this class of work. The centre picture (in the absence of numbers it is a little difficult to indicate with certainty which picture is being referred to) in an oval mount, is delicately tinted, the flesh being especially good; the expression in the eyes is well rendered, and the hair is nicely lighted, with a complete absence of wiriness or sharp rendering of individual hairs. The large head immediately below this is softly lighted, and there is a feeling of atmosphere, or space, round the head which is satisfactory. In the large head of a child in the centre at the top of the display Mr. Harrison has not been quite so successful, the reflections are too large, particularly that in the right eye, and should have been carefully reduced in size.

The display from her studio at St. Ives, in Cornwall, which Mrs. Bainsmith has sent up, is an ambitious one, but the work needs taking just a little further before several of the portraits could be termed really good. The most successful portrait photographers are those who study the work of others and gradually eliminate the defects they notice by comparison in their own work. It is one of the difficulties which workers in isolated places experience that they have such few opportunities for this comparison. The enlarged portrait of a gentleman, presumably Sir Charles Tupper, would have been more effective had the dark background extended right across the figure. At present the outline of the shoulder and arm is very insistent. The large panel portrait printed in red lacks any

point of interest. The face does not in any way dominate the picture, nor is the position of the figure particularly graceful. The colour used in finishing does not match the colour of the print, and gives to the flesh round the ear a dirty appearance.

Mr. James Clark, of Hanger Lane, Ealing, W., shows several pictures, the best of which is a portrait of a laughing boy which is framed in a circular wood frame. The expression in this, and in the portrait of a lady in a bonnet, which is hung close to it, is undoubtedly good, but these are almost the only exhibits in which the expression is satisfactory. The others, or most of them, convey the impression that more attention has been paid to technical points, the arrangement of accessories, dress, and other details, and that the sitter has to some extent wearied, and freshness and spontaneity have been lost. These points are not unimportant, but they should not be placed first. We believe in ninety-nine cases out of a hundred the sitter values expression most. The portrait of John H. Gear, Esq., is a trifle theatrical, perhaps, but is very characteristic. Of "To the Land of Nod" we have nothing good to say. The whole thing is quite unconvincing. We have yet to learn that it is usual for young ladies in baronial mansions to undress in the hall and light themselves upstairs attired in their nightgowns. If Mr. Clark had sat down in front of this picture and carefully thought it over, we feel sure he would not have exhibited it. Better still would it have been to think the print over before making so big an enlargement.

In the prints by Histed, 42, Baker Street, W., we note a rather curious effect of shadow on both sides of the face, the portion of the face nearest the camera being the best lighted. The effect may be satisfactory in certain instances, but carried to the extent seen in this display is apt to savour rather of an affectation. We have a bit of good modelling in the head of Forbes-Robertson, but unquestionably the best portrait of all is the head of Sir Henry Irving.

The portrait we like most in Lambert Weston and Sons' exhibit is one of a very little girl, in the centre of the bottom row. There is an absence of distracting accessories so painfully present in the portrait of an older child on the left-hand side, where, also, the pose is somewhat affected. One or two nice miniatures are shown, but another is spoilt from the colour scheme point of view by a red flower in the hair.

The work of Miss Lena Connell we regard as the best all-round example of conventional professional work, and it evidently attracts to her studio at 50, Grove End Road, St. John's Wood, a number of celebrities. There is here a very happy combination of good, sound commercial work, with just enough artistic feeling for the well-educated public. The remarkably even character of the portraits shown is notable; either Miss Connell always attains a high standard, or knows what to select and what to reject from her recent sittings for the purpose of display. The enlargements we like least. No. 17, Vera Marks, is a beautiful portrait of a beautiful child sitter, the soft brown eyes and gentle expression, with a certain suggestion of latent womanhood, and an entire absence of "pose" making an altogether charming picture. It is a long time since we saw a child portrait which pleased us so much. No. 14, "Who Are You?" is a pretty conceit, a child looking at a doll in

a chair. In an unnumbered print, a full-length portrait of a lady with the face turned to the camera, there is a rather strong light on the hip which somewhat distracts the eye, and which might have been slightly lowered by reduction on the negative.

Mr. William Crooke, of Edinburgh, fills the south wall with an imposing exhibit, quite in the style which he has associated with his studio. Work such as this is to an extent apart from criticism, for it cannot be judged by the conventional canons of commercial portraiture. In one or two instances we should have liked to have seen the shadows on the flesh a little less heavy, though it is possible the light on the pictures might be better. There is a fine portrait group which should be studied by those who want to keep accessories properly subordinated.

The most extensive display in the room is that of W. and D. Downey, of Ebury Street, S.W., and amongst the photographs are many of various members of the Royal Family. Nos. 20, 21, 22, and 23 are probably exhibited on account of the positions occupied by the sitters rather than because of any special excellence as photo-

graphic portraits. Frame 29 contains three portraits, presumably theatrical pictures, which are pleasing and entirely suited to this class of work. No. 27 is a good specimen of commercial coloured work, the colour scheme being quiet, and yet sufficient to raise the picture above a mere piece of tinting. The centre print in No. 7 is a good bit of work, and No. 11 gives some flesh tones, the values of which are as near right in relation to the light draperies as the general public will accept. No. 32 of the pigmies is more interesting than artistic, and has no doubt been included as being topical. No. 9 fairly successfully solves the problem of high lights on a court dress without heavy shadows or too dark flesh tones. The large case of miniatures and ceramic enameled contains some good specimens of these classes of portraiture.

Mr. Hollyer, of 9, Pembroke Square, W., shows three portraits and three reproductions of works of art. The reproductions are, we consider, the finer work. The portrait of the late G. F. Watts seems to show signs of enlargement, and, frankly, we do not like the fingers stretched across the arm of the chair.

THE TRADE SECTION.

Every available space in the Fountain Court is occupied by trade exhibitors this year. Messrs. Wellington and Ward, on the left hand of the entrance, have had Mr. George Walton design a sort of kiosk for them, and have thus obtained better means of displaying negatives on Wellington films and plates, and prints and enlargements on the various papers of their manufacture. Within the structure, at approximately hourly intervals, Mr. John H. Avery demonstrates the sepia toning of bromide prints by the "sulphide" process.

The stall of Kodak, Limited, on the other side of the entrance, displays, of course, the latest models of Kodak cameras and the Kodak tank developer. As these pieces of apparatus have been, or will be, reviewed in our pages, we need not enlarge on them here. A selection of enlargements from negatives made by H.M. Queen Alexandra is a notable feature at the Kodak exhibit, where also demonstrations of developing and printing are given at frequent intervals.

A tour of the Court from left to right brings the visitor first to J. H. Dallmeyer, Limited, whose exhibit represents their manufacture of substantial high-class tourists' cameras. The item of special interest, however, is a form of the "Adon" telephoto lens specially adapted for the No. 3 Folding Pocket Kodak. The back component of the No. 3 F.P.K. lens is a single unachromatic glass, but on substituting for the front lens a telephoto attachment designed by Mr. T. R. Dallmeyer, the whole combination is corrected, and gives sharp pictures up to a magnification of two. This result is obtained without greater extension of the camera. As the new "Adon" is only about the size of a Watkin's cylinder meter, and can be fitted to the lens in a few seconds, the attachment ought to be largely used.

Messrs. Sanger Shepherd show chiefly apparatus for three-colour and scientific photography, including an improved model of a half-plate camera for survey work. Messrs. Houghtons, Limited, make an enticing display of hand and stand cameras, chiefly of the Sanderson pattern; but perhaps one exhibit of theirs of special interest to the professional photographer is the "Phosys" file for the storage of negatives or prints on the card-filing system.

The firm of C. P. Goerz follows its own precedents for several years past in exhibiting enlargements from negatives taken with Goerz anastigmats, but the most striking of the present examples are those taken with the Goerz telephoto lens. Another novel exhibit is an apparatus for the photography of wild animals by flashlight, the exposure being made by the animals themselves. The apparatus has been made at the Goerz factory for the German explorer, Dr. Schilling, who has perfected the system of flashlight photography employed by Shiras in America, in which the act of exposing the plate is very

advisably left to the animal itself. The camera is a special form of the Goerz-Anschütz folding, and the focal-plane shutter is connected with an electric release, by which it is actuated at the same moment that a flash powder is fired. Both these events take place at the same moment, the causative factor in the case being the lion or tiger across whose homeward path the photographer has spread a cord from the apparatus.

Messrs. W. Watson and Sons exhibit a large selection of apparatus, including a new pattern of the Argus reflex camera, fitted with square reversing frame.

"Chess Brand" printing paper—P.O.P., bromide, and gaslight—occupy a tastefully arranged alcove, next to which is the stand of Sanders and Lrowhurst displaying latest models of the Birdland camera and the Southport enlarging easel.

The Platinotype Company's stand, as the scene of demonstration of this beautiful printing process, attracts, perhaps, more visitors than any other exhibit in the gallery, and this year the printing of a platinotype is carried through from first to last before the eyes of the onlooker. A battery of four mercury-vapour lamps fixed some 4 in. from a printing frame, is found to permit of a print being made from a good negative in about seven minutes, and the rest, as the company's demonstrators have the enviable task of proving, is soon over.

The Fountain in the entrance court is covered by the stand of Meister, Lucius and Brüning, whereat is demonstrated the new tricolour process of pinatype. Mr. Ernest H. Schol, of the firm's scientific chemical staff, gives demonstrations of the process, an account of which appeared in these columns a week or two ago, and is further explained this week in the report of a lecture by Mr. Schol before the Croydon Camera Club. A considerable number of specimens of the process are shown in the North Room, and include several good examples of trichromy. Others are far from satisfactory, and in acknowledging the candour which prompts the makers to exhibit them, it must be added in extenuation of their defects that the process is still very young, and the workers of it in Messrs. Meister's works do not profess to be experts in photography.

In the North Room, to the right of the entrance, the first display to attract notice is that of Ilford, Limited, who have essayed with considerable success the difficult task of composing an exhibit from a number of competition prints. There is a great deal of good photography in the numerous frames in this space, and the general scheme of decoration is harmonious and pleasing. With the temptation to put forward a more striking display of large work of the usual order,

Messrs. Ilford, Limited, pursue the wiser policy of showing the public the results obtained on their products by the amateur and professional user.

The exhibit of Photolinol, Limited, is divided between enlargements in oil, pastel, and water colour on "photolinol" as a base, and specimen prints on the new "Angelo" sepia platinum paper.

The Gem Dry Plate Company have a small, but striking, display of results on "Gem" plates and paper. Messrs. Rogers and Webster exhibit their "Multi-screen," an arrangement of hinged frames which fold back against the wall and can carry a number of prints, frames, etc., many times greater than that permitted by the same area of wall space. Quite a valuable accession in a photographer's show-room. The Ozotype Company keep their non-transfer pigment process in mind by the "Ozotype Album," next to which is the collection of the Paget Prize Plate Company, a remarkably fine exhibit of prints on the Paget gelatine and collodion papers. Of these, special mention must be made of the Collodion Cream Crayon P.O.P., an exquisite matt collodio paper eminently suited to all kinds of high-class professional work.

The last and largest exhibition in the room is that of the Autotype Company, divided into three sections—carbon reproductions of well-known paintings, "Autogravure" reproductions of portraits by A. S. Cope, A.R.A., and carbon enlargements from photographers' negatives. We would not exalt the interest of the last above that of the other two, for we would emphasise to photographers the opportunity offered in the Autotype Company's publications of imparting a handsome appearance to a show or reception room. There is no cast-iron law to the effect that the photographer's window or showcase should be occupied exclusively with specimens of the ordinary commercial kind. A handsome display of acknowledged works of art might very well supplant the conventional cabinet and enlargement on occasion, and there is no reason also why the sale of such reproductions could not be added to many photographers' businesses. The third section shows the admirable work the Autotype Company can produce from photographic negatives.

Photo-Mechanical Notes.

The "Enamel" Resist.

We have more inquiries relating to the resist for printing half-tones on metal than on any other process matter. Yet if the principle of the resist was grasped, nothing should be difficult about making the solution, nor should it easily go wrong. The essentials are fish glue, bichromate of ammonium, and water. If it is required to have the solution print quickly, as much bichromate should be added as possible, but not beyond the point where it begins to crystallise out when drying the film. The amount of water added will depend upon the thickness of coating required, and this again should depend upon the character of the negative and the kind of resist wanted. A large shadow point will stand more chance of printing small with a thick solution, while a thin solution is better for a negative with extremely minute shadow dots, as these, in a thick film, will tend to "bung up." If a rich chocolate-coloured enamel is required after burning in, then a thick solution must be used. If the bichromate is made up in saturated solution, this may be added to Le Page's clarified glue in equal quantities, and then water added until found to give the desired viscosity of solution. A drop or two of ammonia may be added to make sure that the solution is not acid. The addition of white of egg is not necessary, and it is questionable if the increase of sensitiveness gained by the addition of chromic acid is worth the risk run

of turning the solution more or less insoluble and causing "scummy" prints.

The Arc and Eyesight.

THE enclosed arc now in use in all photo-engraving studios should not be looked at with the naked eyes, as, although apparently less bright than the ordinary electric arc, the ultra-violet rays that give the value to this form of lamp are particularly damaging to the eyesight. The blue goggles sold by opticians are not much protection, as they probably let through most of the ultra-violet light, while smoked spectacles are generally too light for the purpose. However, deep neutral-tinted glass can be obtained from the glass merchant at the rate of about 2s. per square foot. A small circle or square should be bound round with lantern binding strip and carried by the operator in his waistcoat pocket for use whenever he requires to look at the lamps burning.

A Popular Account of Process.

No. 78 of the "Electrician" handbooks is devoted to the subject of "Photo-engraving," and treats in detail of line work, half-tone, and photogravure. Each process is briefly but lucidly described, and all necessary formulæ are given. There are some excellent half-tone blocks showing a negative and positive and various pieces of apparatus. The price of the pamphlet is threepence, and the writer is Mr. Donald Cameron Swan, of the Swan Electric Engraving Company—certainly a high authority on process matters.

The Reproduction of Pencil Drawings.

At the Manchester Municipal School of Art there is at present an exhibition of studies by the late Sir Edward Burne-Jones. The catalogue for this has been prepared by the Photographic and Printing Crafts Department of the Municipal School of Technology, and an excellent piece of bookwork it is throughout. To illustrate it, permission has been obtained to reproduce fifteen of the studies, and these are quite admirably done in half-tone. Though most of them have the half-tone tint running through the background, the device of printing the blocks on very white paper, and then trimming the print down and mounting on a very dark green cover paper, entirely masks any degradation of background, and makes the reproduction of the pencil work stand out most effectively.

At a meeting of the City of London Common Council on Wednesday, an amusing incident in the proceedings was the taking of a flash-light photograph of the members "in Court of Common Council assembled." The flash-light mixture created a tremendous "bang," while the Chamber was filled with smoke. At the same time, there was a fall of black particles, which descended in a shower upon the heads of the members. The photograph, it may be added, was taken for reproduction in a new publication about to be issued.

B. J. EDWARDS and Co.—Mr. Roland P. Stone asks us to announce that his connection with Messrs. B. J. Edwards and Co. has ceased, the business having been purchased by Messrs. Johnston Matthey and Co., Limited.

THE South London Photographic Society, following the plan adopted last year, extend an invitation to all unattached photographers to attend the elementary evenings held alternate Mondays at their headquarters, Collyer Hall, Peckham. Last session a considerable number attended these meetings and expressed themselves much pleased with the help so freely given, and some eventually joined the society. The next meeting will be held on October 23, the subject being "Developers and Developing." Intending visitors should write to the Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E., when a card of admission will be forwarded.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between September 25 and 30:—

PRINTING.—No. 19,446. Improved apparatus for use in photographic printing and retouching. Thomas Clegg, 38, Chancery Lane, London.

FOCAL-PLANE SHUTTERS.—No. 19,817. Improvements in focal-plane shutters and other roller-blind shutters. Arthur Lewis Adams, Birckbeck Bank Chambers, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

PROJECTION LANTERN.—No. 23,685, 1904. The invention relates to projecting lamps for use with Nernst filaments and resistances. To obviate the risk of breaking the filaments, each one is fixed together with its porcelain base on a non-conducting plug or disc, which also carries the resistance. The plug has a screw-thread on its periphery on to which two pieces of tube are screwed, one from each side; one of the pieces serves as a cap to protect the filament, and the other, which is preferably longer, encloses the resistance. This latter tube carries two projecting lugs having holes whereby the lamp is supported on the usual carrying pin. The outer end of this latter tube is conveniently covered with perforated sheet metal in order to provide thorough ventilation for the resistance. A hole is provided in the centre of the perforated metal to enable the connecting wires to be passed into the lamp. Leo Kamm, 27, Powell Street, Goswell Road, London, E.C.

The following specifications are open to public inspection before acceptance under the Patents Acts, 1901:—

TRIPOD STANDS.—No. 18,332. Tripod stands for cameras, etc. McLeod.

LIGHT FILTERS.—No. 19,202. Process for the manufacture of three-colour screens for use in colour photography. Krayn.

New Apparatus, &c.

The Bausch and Lomb "Automat" Shutter. Sold by A. E. Staley and Co., 19, Thavies Inn, London, E.C.

The 1906 model of this well-known shutter has been submitted to us by Messrs. Staley, and we find it "in form and moving" as convenient an instrument of this class as could be desired. The shutter, of course, is of the diaphragmatic type, and is threaded back and front for the reception of the components of an R.R. lens. It is provided with an iris diaphragm, the scale of which can be marked for any given focal length. The three movements of the shutter—instantaneous, bulb, and time—are obtained most simply by rotation of the central disc, which is marked for exposures of 1, $\frac{1}{2}$, 1-5th, 1-25th, 1-50th, and 1-100th of a second.

The "Rajar" Film Slide. Made and sold by Rajar, Limited, Moberley, Cheshire.

This piece of apparatus embodies a new system of daylight loading and changing for cut films. The changer itself is light and compact, being constructed of wood and no larger than an ordinary double dark-slide. It is made in the size to fit ordinary popular patterns of camera—and can be sent out ready for use on naming the camera—

or supplied with its edge ungrooved so that any cabinet-maker can cut the groove for a trifling sum. The film slide is loaded in daylight with separate cut films, which, after exposure, are collected up to the number of about a dozen in the film slide. Each film is supplied in a light-tight envelope, which is inserted in the slide. Here it encloses the film as shown in Fig. 1, the tag projecting from the top of the slide. On pulling the tag a short distance, the loop or "cap"

Fig. 1.

is drawn behind the envelope and the film is caught on its two extreme corners by two steel wire springs. The figures show the stages in the charging of the slide:—Fig. 2, film envelope inserted in front of shutter by passing through valve between the shutter and the body of the slide. Fig. 3, tag raised as far as it will come, to draw the "cap" behind the envelope. Fig. 4, envelope pushed back into the slide in front of "cap," and film caught by wire hooks. The

Fig. 2.

Fig. 3.

Fig. 4.

envelope and cap are now pulled right out of the film slide, and the film is left ready for exposure, as shown in Fig. 5; the shutter of the slide in this and other drawings being shown removed to disclose the stages of the process. After exposure, the film is transferred to the back part of the slide simply by withdrawing the slide. The price of the slide is 10s. 6d. in the quarter-plate size, and films of the same size, special rapid or ordinary, are 2s. per dozen. The apparatus

Fig. 5.

weighs only a few ounces and is absolutely free from mechanism. The manipulation of the envelopes is easily understood, and the new system should appeal strongly to the amateur tourist photographer who fights shy of dark-rooms, but yet wishes to carry with him the means of making an unlimited number of exposures. The lightness and flatness of the Rajar envelope-packages are two great points in their favour.

New Materials.

"Synoloids." Made by the "Synoloids" Company, 4, North St. David Street, Edinburgh.

When the development of faintly printed P.O.P. was suggested some years ago, it was thought that this new power, placed in the hands of the busy printer, would revolutionise the production of prints on gelatino-chloride paper. The process, however, although carefully worked out, and brought to a practical and reliable state, did not appear to "catch on" to any great extent, and from time to time new formulae and preparations for developing out an image on these papers have been advocated. The latest claimant for popularity in this direction is called "Synoloids." Synoloids take the form of little tablets, which are put up in convenient form in glass tubes. A pair of these tablets will, when dissolved in water and applied to P.O.P., on which only a slight impression of the image has been formed by light, develop the picture right out in less than a minute, and with a pleasing range of tones from warm chestnut brown to nearly black. No other chemicals, with the exception of hypo, are needed, and for the busy worker who has no time to fully print out his P.O.P., we can conceive no simpler method for the production of prints with all the attributes of the completely-finished and toned result. The depth to which the original printing has been carried affects the final tone. Very faintly printed prints develop a very dark tone, almost black, while those that have received a more prolonged exposure give warmer tones. Still blacker tones can be obtained by using a special Synoloid tablet. The developing process is conducted as follows:—Immediately before use a couple of the tablets are dissolved separately in two ounces of water. These two solutions are then mixed, and poured straight on to the dry print in a perfectly clean dish. In a few seconds the image will begin to strengthen and development will be complete in about half a minute. The print is then transferred to the fixing bath—hypo, three ounces; water, one pint; and a certain amount of loss of tone takes place—so the development must be carried further than appears necessary. We think, however, that an intermediate washing between development and fixing would be more conducive to permanency, as there would then be less chance of sulphurising action on the print. "Syno." P.O.P. (made by the Gem Plate Co., Ltd.) is specially recommended for this treatment, but it is applicable to any other variety. The tablets are not expensive, and full particulars will be sent free on application.

The Latest Colour-Photography.—A so-called "Mars-Star" process is announced, by which filters, etc., are dispensed with, and—to quote the circular — "amateur photographers can now sort out their favourite negatives and print from them a bromide print, and after immersing the print in the developing colour compounds, the bromide print is re-developed up in colours, the compounds having the power to produce the colours in re-development according to judgment." The price of an outfit is half a guinea for amateurs; special licensees, presumably at a price, are to be granted to professionals. We are afraid the company will not get along very fast on these lines.

We have been asked by the hon. secretary of the Hackney Photographic Society to remind our readers that entries for the Hackney Exhibition close on Saturday, October 21. Pictures will be collected from the R.P.S. and Salon free of charge. Full particulars will be sent by Walter Selfe, 70, Paragon Road, Hackney, N.E.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Oct.	Name of Society.	Subject.
13.....	Leicester Lit. and Philo. Society	"Factorial Development of Negatives." Demonstrated. The Chairman, "Trimmer and Trimming of Prints," "Use of Lanternscope." Members' Slides.
13.....	Colne Camera Club.....	"Barnet" Post Card Competition. Mr. J. K. Harvey.
14.....	R.P.S. Exhibition New Gallery	"A French Wonderland and the Devil's City." Mr. James A. Sinclair, F.R.P.S.
16.....	Dewsbury Photo. Society.....	"Gun Bichromate." Demonstrated. Messrs. Lyles and Dawson.
16.....	Widnes Photographic Society..	"Views of Norway." The late Mr. Paul Lange.
16.....	R.P.S. Exhibition New Gallery	"Some Unfamiliar Denizens of Rivers, Lakes and Ponds." J. Martin-Duncan.
16.....	Wandsworth Camera Club	"Amilaxion Lecture on "Landscape Photography."
16.....	Bowes Pk. and Dis. Ph. Soc.	"Ozotype." Mr. Thos. Manly.
16.....	South London Photo. Society ...	"Toning Bromide Papers." Rev. H. O. Fenton; and the <i>Amateur Photographer</i> 1905 Prize Slides.
16.....	Halifax Camera Club	"St. Alban to Lichfield." Mr. G. Birgley
16.....	Luton Camera Club	Exhibition of the <i>Amateur Photographer</i> Prize Slides.
16.....	Barrow Naturalists' Field Club	"To the Arctic Regions and Back in a Fortnight" (illus.) Mr. M. Stables.
16.....	Southampton Camera Club	"A Founder of Empire" (illus.) F. G. Ryder.
17.....	Thornton Heath Photo. Society	Demonstration of Rotograph and Rotox Gaslight Papers. By the Rotary Photographic Co., Ltd.
17.....	Barrow Naturalists' Field Club	Opening of Enlarging Lantern.
17.....	St. Helens Camera Club	"Platinotype." Mr. J. Collins.
17.....	Hackney Photographic Society	Excursion Prints Judged and Criticised. (Entries for Exhibition due.)
17.....	Jersey Photographic Society ...	"The Romantic in Landscape."
17.....	Bristol Photographic Society ...	Enlarging Demonstration by Mr. H. R. Harford.
17.....	Sunderland Camera Club	Half-yearly Meeting.
17.....	Nelson Photographic Society ...	Demonstration—Lantern Slides. Mr. W. Baldwin, Foulridge.
17.....	Birmingham Photo. Society.	Demonstration on "Oil Printing." Mr. James Gale.
17.....	Holmfirth Photographic Soc....	"Art." Mrs. G. L. Richardson.
17.....	Darlington Camera Club	"How to Make a Lantern Slide." Mr. H. L. Thomson.
18.....	Croydon Camera Club	"The Carbon Process." Lionel Kough.
18.....	Boro' Poly. Photo. Society	"A Week-End in Venice." Mr. A. E. Pain.
18.....	Cricklewood Photo. Society.....	Demonstration by Messrs. Kodak, Ltd.
18.....	Coventry Photographic Club	"Hand Camera Work." Mr. J. I. Bates.
18.....	North Middlesex Photo. Soc....	"Lantern Slide Making by the Carbon Process." Mr. Louis Dick.
18.....	G.E.R. Mechanics' Institution	"An Amateur on Colour Photography." Mr. G. U. Haslam.
18.....	Redhill and Dis. Camera Club.	"Homeward Across the World." Mr. A. H. Dunning.
19.....	Southport Photo. Society	"Rome and Southern Italy." Mr. T. E. Rice-Jones.
19.....	Sheffield Photographic Society	Demonstration "Bromide Enlarging." Mr. Geo. Tomlinson.
19.....	London and Prov. Photo. As....	"Through Dalmatia and Bosnia." Mr. C. Dalgarno.
19.....	Liverpool Amateur Ph. Assn....	"Making of Enlarged or Reduced Negatives, by Reflected Light from an Untoned P.O.P. Print." Mr. F. Rust.
19.....	Chelsea and Dist. Photo. Soc. ...	Demonstration "Page-Croft Pigment Paper." Mr. R. C. Gibbs.
19.....	Glasgow Eastern A.P.A.	"Artistic Mounting of Photographs." Mr. J. S. Melville.
19.....	Handsworth Photo. Society.....	Demonstration — "Toning Bromide Prints." Mr. J. A. Swift.
19.....	Wimbledon and Dis. Cam. Club	"Hampton Court Palace." Mr. J. Munro.
19.....	Hull Photographic Society	"Warwickshire, Gloucestershire, and the Wye Valley." Mr. Godfrey Bingley.
19.....	Balham Camera Club	Members' Night.
19.....	Rodley, Farsley & Calverley P.S.	"Steroscopic Work."

ROYAL PHOTOGRAPHIC SOCIETY.

The opening meeting of session 1905-6 was held in the New Gallery, Regent Street, on Tuesday last, October 10. Major-General Waterhouse delivered the presidential address, on "By-Paths of Photography." He instanced the many fields of photography which were yet unexplored, and went on to review the numerous and valuable services which the camera had rendered to the arts and sciences. On the proposition of Mr. J. C. S. Mummery, seconded by Mr. John Spiller, a vote of thanks to General Waterhouse was carried.

CROYDON CAMERA CLUB.

On October 4, "Pinatype," the new system of three-colour photography (described at length in the B.J. for September 22), was demonstrated before the members of this society by Mr. Ernest Scholl, representing Messrs. Meister, Lucius, and Brünig, of Hoechst-on-Main. In some respects it bears a certain family likeness to the system evolved some time ago by Messrs. Sanger, Shepherd and Co., but there are cardinal points of difference. In each case three negatives are obtained under well-known conditions, yellow, blue, and red positive images are obtained, transferred to paper, and superimposed. Messrs. Sanger-Shepherd, however, print direct from the original negatives on bichromated gelatine films, supported on thin celluloid, dissolve by hot water the parts least acted upon by light, dye the reliefs so formed, and transfer the dyes to a suitable prepared paper by contact. In Pinatype, three bichromated films on glass plates are exposed behind three positives obtained from the original negatives, either by contact or by enlargement, the bichromate is then removed by washing, and the films, which are left intact, are dyed as in the former process. The unhardened parts of the films—representing the deep shadows of the positives—take the dyes readily, the half-tones less so, and the highest lights little or none at all. A piece of gelatine paper is then squeegeed into contact with one of the dyed films, and a portion of the colour is transferred to it by absorption. The paper is next successively squeegeed into contact with the two remaining dyed films, correct registration being effected by looking through the glasses supporting them. After the demonstration the president (Mr. W. H. Smith), after a passing allusion to the magnitude of the Aniline Dye Works at Hoechst-on-Main, which employ 5,000 workmen, consume over 600 tons of coal per diem, and possess over forty-two kilometres of railway track and eighteen locomotives, drew attention to the fact that the bichromate films were in the nature of negatives; if these, and the intervening positions, could be dispensed with, and the original negatives, by any means, employed direct for transfer of the dyes to paper it would tend towards simplification. He thought he had heard some such idea advanced in the past. Mr. E. A. Salt was of opinion that few amateurs would care to orthochromatise plates by the bath method—which necessitated careful manipulation and a drying cupboard—or undertake the manufacture of three filters of definite ratio to each other; these might with advantage be supplied adjusted to English brands of plates. He inquired whether long or short washing after dyeing an ordinary plate affected its colour sensitiveness. Mr. C. E. Kenneth Mees, said that the length of after-washing did not seem to influence the colour sensitiveness; a certain amount to remove excess of dye was necessary. The dye appeared to enter into a definite chemical compound with the silver bromide, which, *per se*, was not affected by long washing. (See Dr. König's article on another page. Eds. B.J.P.) As to the adjustment of filters for various brands of ortho plates, in ordinary three-colour work these were very much alike, Lumière's filters excepted. For instance, plates dipped in orthochrome T would work well with Messrs. Sanger Shepherd's filters. He agreed that it was difficult to successfully bathe and dry plates without special appliances, but it should be remembered that a bathed plate was superior to the ordinary commercial panchromatic plate in the proportion of about 5 to 1. With reference to the President's suggestion, he also recollected something of the sort being advanced. It was true that with a strongly alkaline pyro developer, where the silver was most acted upon there the film was toughened most. This accounted for the relief frequently observed in negatives. He did not, however, think that this could be utilised in the direction proposed. The second half of the evening was devoted to an exposition on lantern-slide making by Mr. H. P. C. Harpur.

MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY.

Mr. Charles J. Harrison gave a lecture and demonstration on "Enlarged Negatives," in the Society's Rooms, Market Street. The lecturer expressed his conviction that the whole routine of enlarged negative making was simplicity itself, there seemed no possible pitfalls for anyone sufficiently advanced to make a fair technical negative by direct methods, and once obtained, the chances of getting a good result through the medium of a large negative was distinctly more favourable than the chance of getting a good bromide enlargement. Turning to the practical side of the question, he said the first operation was to make a transparency or positive from the negative to be enlarged. This was usually done by putting the negative into a printing frame and placing a dry plate in contact with it in the same way that one would put in a piece of bromide paper. It is then exposed to the light and developed. All the success of the operations depended upon this positive, and he was convinced that the best results were obtained from a positive low in contrasts. To describe the type, he would say that a positive which looked like a thin, washy lantern slide made the best large negative. Any attempt at brilliance or strong contrasts must be avoided or the large negative would suffer. He believed the carbon process gave the ideal positive. In the first place they knew that they had got a true positive, nothing had been sacrificed in development through over or under exposure, and, above all, these transparencies were comparatively soft and low in their scale of gradation. Some workers advocated the use of plates with lantern-slide emulsion, and others process plates for the production of the transparency; but, personally he always used a rapid plate, as there was less chance of getting a contrasty positive. In making the exposure on to the dry plate give full, but not over-exposure, and develop with a dilute developer—a normal developer with quite twice its bulk of added water. The transparency must develop a certain length of time, say not less than seven or eight minutes, or the gradations of the positive would not correspond with those of the negative. To enable them to form some sort of a prior judgment of the exposure to be given he pointed out that an ordinary slow plate was about three times the speed of rapid bromide paper, and a rapid plate about three times as fast as an ordinary. Another method of making transparencies was by projection either through one's own camera by daylight or through an ordinary enlarging lantern in the dark room. If the former is chosen, as it might be through the convenience of being able to do it at home, then it was necessary to fix up the negative either in a window so that the clear sky was transmitted through it, or else a reflector was so fitted that an even light was reflected through it. Then the camera was fixed up at the same angle and parallel to the negative, and a plate was exposed in it. When making transparencies in this way he had not found it necessary to exclude the light that came between the negative and the camera. If the transparency was made by artificial light through the enlarging lantern, then it was only necessary to proceed as if making a bromide print, except that for the piece of bromide paper a dry plate should be substituted. The focussing, of course, should also be done on an old dry plate. Mr. Harrison also described a method of printing in the clouds. First, make a transparency of the foreground. Wash and dry it, then roughly cover up on the glass side of the transparency, either with black paint or a paper mask, the whole of the foreground, leaving only the bare outlines showing. Then put the cloud negative in the enlarging lantern, focus it to the correct size, and fix on the screen a dry plate, in front of which place the transparency of the foreground, film to film, keeping it fixed there until the cloud exposure was made. Obviously the cloud must fit the foreground, and they only needed binding together in register. In conclusion, the lecturer advised the use of backed plates, both for the transparency and the final large negative.

PHOTOGRAPHIC CLUB.—Meeting held October 4, Mr. H. Snowden Ward in the chair. Mr. R. R. Beard read a paper on a "Cinematographs, Past and Present." He referred to Beale's chorentoscope as the predecessor of the film kinetograph: it contained the Geneva stop action present in the modern instruments. The patents of Friesse, Greene, and Evans in 1889 embodied the first practical methods of animated projection. The machine was capable of showing moving pictures at the rate of ten or more per second. In 1895 Lumière's instrument was shown in Paris, and in that year and the following the cinematograph boom might be said to have commenced. The machine of Birt Acres appeared about the same time as Lumière's. Mr. Beard illustrated the essential features of these and other machines, and explained the so-called "dog" motion used in the Bioscope and other instruments. He finally exhibited a working model of an improved projector of his own construction, in which the operator can bring a film into the correct position on the stage while the machine is running. A number of films taken by Mr. Martin Duncan were exhibited in the machine. On the motion of Mr. F. A. Bridge, a vote of thanks was passed to Mr. Beard.

ABERDEEN PHOTOGRAPHIC ASSOCIATION.—The annual general meeting of this association was held in the rooms, No. 54, St. Nicholas Street, on Friday last. The secretary's report was very satisfactory, and the treasurer's report showed that while still adding apparatus to the already extensive outfit, there was a balance on the right side. The election of office-bearers resulted as follows:—President, A. S. Anderson; vice-presidents, J. Main and G. Robertson; committee, W. Main, J. Milne, W. Milne, J. Milne, J. A. Masson, P. Wilkie, Bearsley, G. R. Ford, and G. H. Henderson; lanternist, W. T. Borthwick; treasurer, James Dunn; secretary, A. Gray, 18, South Mount Street; and correspondent, Mr. Deans, 204, King Street.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the White Swan, Tudor Street, E.C., on October 19, at 8 p.m., Mr. C. Dalgarno will give a lecture, "Through Dalmatia and Bosnia." Visitors are especially invited.

ROTTERHAM PHOTOGRAPHIC SOCIETY.—The annual meeting was held on Tuesday evening of last week at the Town Hall Assembly Rooms, Rotherham. The report of the year's work recorded progress, and the financial statement showed a balance in hand of £14. The officers for the coming year were elected as follows:—President, E. F. Hubbard; vice-presidents, J. Leadbeater, W. Firth, and J. W. Stamp; treasurer, F. Oldham; secretary, H. C. Hemingway; assistant secretary, C. E. Davis; auditor, W. B. Davison; curator, F. Sergeant; and an executive committee was appointed. A lecture on "Stereoscopic Photography" was afterwards delivered.

NORWICH PHOTOGRAPHIC SOCIETY.—At the annual meeting of this society, on October 2, the following were elected office-holders for the ensuing year:—President, A. E. Coe; vice-president and chairman, E. Peake; vice-chairman, B. Bullen; committee, H. Butcher, S. Taylor, A. Robinson, C. S. Tungate, W. Hume, and A. Brown; hon. treasurer, H. C. Laycock; hon. secretary, J. T. Tanner.

BRENTFORD PHOTOGRAPHIC SOCIETY.—The annual general meeting of this society was held on Tuesday evening last, October 3. A satisfactory report and balance-sheet were presented. The president, Rev. T. Eland, M.A., F.R.G.S., was again unanimously re-elected, and Mr. Hilton Grundy, who recently resigned the hon. secretaryship, was elected as chairman. Mr. Frank H. Read was elected as hon. secretary and treasurer, and will be glad to forward particulars of membership. An interesting syllabus has been arranged for the ensuing season, and meetings will be held on first and third Tuesday evenings in each month. The society now possess most comfortable headquarters at the Brentford Public Library, and a photographic library in connection with the society is in course of formation. The hon. secretary will be pleased to receive any publications of interest

in this direction. A record and survey section of the district is also being formed under the guidance of Mr. Fred Turner, F.R.Hist.Soc.

BOLTON AMATEUR PHOTOGRAPHIC SOCIETY.—The annual general meeting of this society was held on Thursday, 5th inst., at its headquarters, Corporation Chambers, Corporation Street, Bolton. From the reports of the secretary and treasurer it appeared that the last session had been on the whole very satisfactory. Amongst features of the coming season's syllabus to which special attention is to be devoted is the "open night" and short demonstrations to be given by some of the members themselves. The society extends an invitation to all photographically inclined who are not members to the meeting on Thursday, October 26, at 8 p.m., when, amongst other matters, several systems of storing and registering negatives will be under discussion. The secretary, Mr. T. W. Cross, of 27, Lytham Street, Bolton, will be pleased to answer any inquiries as to membership, etc.

The Wandsworth Camera Club opened their winter session on Monday evening, the 2nd inst., with a demonstration by a representative of the Autotype Company on "Carbon Tissue and Auto-Pastel." The lecturer's manipulation of auto-pastel came as a revelation to many present, especially the way in which the butt end of the brush was used to give the high-lights greater prominence.

The Chelsea and District Photographic Society held the opening of their third winter season at the South-Western Polytechnic on October 5. Some Swiss slides were shown by Mr. J. H. Grafton.

FIXTURE LISTS RECEIVED.

This week we have received from the following societies their programmes of fixtures for the winter session, and in each case we are pleased to note the variety of the fare provided for the members. These fixtures will be noted week by week in the list published on p. 815, and we hope that the hon. secs. or reporters of these societies will send us accounts of the lectures and demonstrations as suggested by our contributor "Hon. Sec." a few weeks ago.

New Book.

"Rezepte und Tabellen." By T. M. Eder. Halle a/S: Wilhelm Knapp. M 2.50.

The first edition of this work, published in 1889, formed the second section of "Eder's Jahrbuch," but with the growth of the latter it was published as a separate volume, and this one is the sixth edition. It is divided into two sections, the one containing formulae for practice, which are those employed in the Viennese school of which the author is the Director, and the other various physical, optical, and chemical tables of occasional usefulness. The work covers every branch of photography.

News and Notes.

LECTURES at the R.P.S. Exhibition.—The following lectures will be given at the New Gallery, Regent Street, during the ensuing week:—Saturday, October 14: "A French Wonderland and the Devil's City," by James A. Sinclair, F.R.P.S. Monday, October 16: "Some Unfamiliar Denizens of Rivers, Lakes, and Ponds," by J. Martin Duncan. Thursday, October 19: "A Mighty Marshland Minister," by E. W. Harper Piper.

MYSTERIOUS Photographs.—We reproduce herewith one of the mysterious photographs referred to in our issue of September 29. Mr.

J. Street, the photographer, can offer no explanation of it. He states that the plates used came out of a freshly-opened box, and the explanation of a double exposure appears to him an impossible one.

METROPOLITAN Photographic Federation.—At a meeting held in the club-room of the Forest Gate M.M. Camera Club, at which seven societies were represented (the chair being taken by Walter D. Welford, F.R.P.S., President of the South Essex C.C.) it was resolved to form this federation for the promotion of the social side of photographic society life and for mutual assistance. A committee was elected to draft out rules, etc. These will be sent for consideration to the societies interested in the movement, and to such other societies as may apply for them. The suggestions received from societies deciding to join the movement will be considered by the Committee, the final draft to be presented for confirmation to a later meeting of delegates. The Hon. Secretary (pro. tem.) is T. Michell. Hon. Sec. South Essex C.C., 180, Browning Road, Manor Park, E.

THE Recording Eye.—The old belief that the last optical impressions of a dying person were recorded indelibly on the coating of the

eyes has been revived by an amateur photographer, who has written to the "Daily Telegraph," and suggests that an impression of the murderer of Miss Money would have been found on her retinas. The suggestion is, however, completely scouted by Dr. Geo. Lindsay Johnson, who thoroughly elucidates the matter. He says:—"As this idea seems to be very widely prevalent, it might be as well if the real facts of the case were clearly stated. The trace of truth underlying the story is based upon some experiments made by the late Professor Kuelme, of Heidelberg, which were founded upon the previous discovery of Professor Boll, of Vienna. The latter discovered that the layer of pigment cells immediately behind the rods and cones of the retina secreted a pinkish purple colouring-matter which spread between the ends of the rods. He called this *Sehpurpur* (visual purple) and found that it became rapidly bleached by light. Kuelme succeeded in taking a photograph, or "optogram," as he called it, of a window showing the panes on a rabbit's eye, and fixing it in a solution of alum. The experiment is extremely difficult to perform, and requires the utmost care and precautions. To succeed in obtaining a portrait of anyone on the eye of a person suddenly killed, the following conditions are necessary, and the failure of any one would probably prevent any portrait being formed at all. The victim would have to be chloroformed and fixed immovably in a dentist's chair, the eyelids held apart by an instrument, and the pupil dilated with a mydriatic. The murderer, in the same way, would have to have his face kept immovable, at a distance previously agreed upon, during the whole of the ten minutes' exposure, while his face was brilliantly illuminated—all extraneous light being carefully excluded. It would also be necessary for the refraction of the victim's eye to have been previously ascertained, and such a spectacle lens placed in front of it as would sharply define the face of the murderer on the victim's retina. The moment the exposure was sufficient the eye would have to be smeared over with lamp black, at once removed from the body in a subdued red-on-actinic light, divided in half, and the back half placed in a solution of alum. If all these directions were implicitly followed the result might yield an image sufficiently distinct to be recognised as a human face, but, in any case, it would be ridiculously small. If, for example, the murderer's face were $9\frac{1}{2}$ in. long and at a distance of one yard from the victim's eye, the size of the face on the retina would be under four millimetres—i.e., a little over an eighth of an inch, nor could it be enlarged, as the light used for that purpose would cause the image to fade." We may, therefore, once dismiss the possibility of any such photographs being formed except in the laboratory and under the conditions above named.

THE SALON SMOKER.—The members of the Linked Ring were "at home" on Tuesday evening last at their Photographic Salon, 5a, Pall Mall East, and at 8.30 the programme of music, recitation, talk, and smoking, to say nothing of drinking, commenced with full house. The new home of the Salon is particularly adapted for a function of this description, and the well-known hospitality of the genial Links found full scope for expansion in their larger quarters. The programme of the evening is usually an artistic production, and this year was no exception. It succinctly states:—"At intervals in the talk, the following gentlemen will amuse and otherwise interest the audience with singing, with piano playing, by comic and tragic reciting, and by other performances. At judicious occasions there will be Scotch whisky and soda water, supported by sandwiches of varied contents." When it is said the "talent" included Mr. Walter Churcher, Mr. Reginald Groome, Mr. George Robins, Mr. Hermann Vezin, and others, to say nothing of "The Odell," the success of the evening can be understood. The gathering included a notable collection of celebrities in the photographic and art world, and needless to say the popular hon. secretary of the Salon, Mr. Reginald Craig, came in for his usual ovation at the termination of the proceedings.

A READER asks:—"Can you give me the address of the Automatic Photoscope and cost of same?" We cannot; but will forward any information to the querist.

THE Multiscope and Film Company, Burlington, Wisconsin, U.S.A., notify us that in addition to manufacturing the "Al. Vista" camera they are makers of the "Badger" plate cameras.

MESSRS. SANDS, HUNTER, AND CO., for many years in Cranbourne Street, Leicester Square, have transferred their business to larger premises at 37, Bedford Street, Strand, London, W.C. Their large stock of high-class second-hand apparatus is more conveniently housed in the new quarters, and the firm begs its customers—some of whom date back to the establishment of the business, more than thirty years ago—to note the new address. Messrs. Sands and Hunter will continue the sale and purchase of reputable second-hand apparatus as the staple features of their trading, but the new premises will give them the opportunity of serving their clients also in other ways.

THE death is announced of Mr. De Lan, Bridge End, Tweedmouth, Berwick-on-Tweed.

Commercial & Legal Intelligence

A DEFECTIVE ROOF.—A photographer named Walter Harry Cox, at the Cardiff County Court recently, sued the landlord of the premises he occupied for damage to his stock of negatives in consequence of the defective condition of the building. The evidence was that plaintiff took a house in Westbourne Crescent from Mr. J. J. Lewis on a seven years' lease. In the attic he stored a large number of negatives kept for repeat orders, and as a result of water entering the attic, 1,111 were destroyed or seriously damaged. He estimated that the value of his repeat orders for the last three years was £196. The defence was that plaintiff did not complain of the condition of the attic until February last, that there was contributory negligence, and that the value of the negatives was greatly exaggerated. Judgment was given for plaintiff for £60, with costs.

FRAUD BY A TRAVELLING PHOTOGRAPHER.—On Monday last at Stroud, Joshua William Humphreys, of Orchard Street, Blandford, Dorset, was charged with having, on August 22, obtained from Edward Shelton, a Stroud tradesman, £7 by false pretences. He was further charged with having, on August 23, obtained £2 from David Mason Lodge, bookseller, of Brinscombe, near Stroud, by a similar false pretence. Prisoner solicited orders for picture postcards, but in neither case had orders or part been executed. He carried a photographic apparatus with him, and offered to take photographs of the district and supply the picture postcards at £7 odd for 4,000. Mr. Shelton said he was induced to part with the cheque which he gave prisoner in view of the extraordinary value of the cards and what he said about his business. Superintendent Biggs said he visited prisoner's house, a small cottage, and there was no sign indicating that any business was carried on there. There were nine other cases against prisoner, the total money obtained by him being £28. Prisoner admitted that he had not supplied any of the orders for which money had been drawn. He pleaded "guilty under extenuating circumstances," and was sentenced to four months' hard labour.

THEFT OF CAMERAS.—Ebenezer James Faulkner, of Green Street, Whalley Range, Manchester, was charged, on remand, at the Guildhall with stealing a number of hand cameras, tripods, microscopic slides and lenses, camera slides and parts, etc., value about £44, from R. J. Beck and Co. (Limited), Cornhill. The prisoner was sentenced to six months' in the second division.

THE INVENTION OF PIGMENT PRINTING.

To the Editors.

Gentlemen,—Being deeply interested in the early history of photography, I have followed closely the weekly notes by "Historicus" in the B.J.P., and am greatly indebted for many points of importance, told, too, with just that personal touch that one misses in the ordinary text-book.

I will be very grateful if you can give me any further information (or references to details already in print) with regard to the following point, which has long puzzled me:—

I gather that when Ponton discovered the method of printing on bichromatised paper he got no further than proving that light darkened the salt. Had he no conception that even in his paper prints the reaction was probably more complex than the darkening of the bichromate? And is it literally the case that no investigations were made—i.e., which were recorded—of the infinitely more important results of light on bichromate when mixed with colloids until Fox Talbot took the matter in hand?

I had always looked upon Ponton as the founder (unconscious, perhaps) of photo-mechanical work, but unless Fox Talbot was directly induced to try the result of mixing bichromate and gelatine, by what he knew of Ponton's work it certainly seems that Talbot is fully entitled to all the credit in this branch of photography.

Talbot was doubtless at work on the problem between 1839, and his first publication of his photogravure process. Is there any evidence as to when and for what reason he came to take it up?

And did he certainly hit on the insolubilisation of bichromatised gelatine before Poitevin, in which case, I suppose, one may fairly look upon the latter's work as lineally descended from Talbot's?

I am ashamed to ask your contributor so many questions on a point which, it may be, I ought to be able to work out for myself from the books that are available, but I had far rather have the deliberate opinion of a careful observer with an unusually good memory, than the statements (too often perfunctorily copied from other books) of the ordinary text-book writer.—Yours truly,

WALTER S. CORDER.

4, Rosella Place, North Shields, October 2, 1905.

[Our correspondent's enquiries are dealt with by "Historicus" on another page.—Eds., B.J.P.]

THE TITLE OF A PICTURE.

To the Editors.

Gentlemen,—I am writing to ask if you would assist me to correct the title of my study, now hung in the "Royal." I sent in two pictures—one "Bereaved" and the other "Betrayed." The authorities have hung "Betrayed" and called it "Bereaved," and, of course, the title does not fit the picture; consequently I did not get a good criticism in your journal. It has been reproduced in the "Illustrated London News" as "Bereaved," and they have taken the title from the catalogue—hence another mistake. The secretary has written expressing regret. I have had several letters from friends asking why I had spoilt my study by giving it an inappropriate title.—Apologising for thus troubling you, and thanking you in anticipation, I am, sir, yours faithfully,

EDWIN H. HAZELL.

Linden Road Studios, Clevedon, October 7, 1905.

Answers to Correspondents.

- *.* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- *.* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *.* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- *.* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- E. F. Bostock, 24, Moorgate Street, Nottingham. *Photograph of Mr. and Mrs. Rodkinson.*
- W. C. Silence, 7, Bank Buildings, Weybridge, Surrey. *Photograph of the Saxon Curfew Bell from the Abbey, Chertsey.*
- J. B. Mumford, 22, Victoria Road, New Brighton. *Three Photographs of Rough Sea at New Brighton.*
- G. A. Dean, 14, High Street, Rugby. *Photograph of Child with "Daily Mail."*
- H. Johnstone, Rockstone Place, Castle-Douglas, Scotland. *Photograph of the Castle-Douglas Bowling Club, 1905.*
- S. H. Greenway, Abington Street, Northampton. *Photograph of the New Zealand and Northampton Rugby Football Teams.*
- H. V. Southgate, 2, Station Road, Maidenhead, Berks. *Photograph of Mary Isabel Horsfield Feeding Parrot, entitled "Pretty Poll."*
- Rev. J. Hill, Holy Rood Rectory, George Street, Barnsley. *Two Photographs of Ceremony of Opening the New Church of the Holy Rood, Barnsley.*
- Miss C. Osborne, 454, Stratford Road, Sparkhill, Birmingham. *Photograph of Child Partially Dressed, Supporting Itself by both Arms on Cushion, Head held up, Baby Laughing.*
- A. Webster, Barnack, Stamford. *Two Photographs of Deeping St. James.*

BOOK ON RETOUCHING.—I shall be much obliged to you if you will mention in your valuable journal: (1) the best book of retouching negatives with knife; (2) where to procure same.—M. BARNARTT.

As good as any is "Retouching," by Arthur Whiting. (Dawbarn and Ward, Limited.) 1s.

C. H. LAWS.—There are lamps on the market serving the same purpose, but we should think there is a certain business to be done, though not a very large one. We should say it would be worth your while to take out provisional protection.

TRADE NAME.—Will you kindly give me an answer to the following? I am about to start a portrait supply, and wish to name it as follows: "G— Fine Art Society." Have I to register it in any way? There is no one in the business but myself; I class myself as manager. But, having it named under a society, I thought I should have to do so. Would "Fine Art Association" come under the same rules.—FINE ART.

You will not have to register the name. Do not you think naming the affair a "society" is a mistake? Would it not be better to call it a company, with yourself as manager, if you do not wish it to be thought the business is your own?

COPYRIGHT.—I shall be greatly obliged if you will inform me whether the enclosed photograph is copyright or not. It is of William Morris, poet and author, who died 1896.—ENQUIRER.

The only way for you to ascertain is by search at Stationers' Hall, London, E.C., but we should say the copyright in the photograph has been registered, in all probability.

H. J. H. asks:—Will you please oblige us with the address of the Executors or the gentleman who has taken over the photographic business of the late Mr. W. King, photographer, of Goldhawk Road, Shepherd's Bush? We wish to obtain some of his negatives.

You probably refer to Mr. Horatio Nelson King. Unless we are mistaken, a letter addressed to his son will bring you the information.

PRIMULINE PROCESS.—In the "Almanac" published by you for 1904,

on page 691, is described a process for printing on woven fabric having for its basis "primuline." May I ask your assistance in letting me know what this primuline is, or where it can be obtained? I should like to try the process, but the local photographic material people can give me no information about the material.

PARTICK.

Primuline is a diazo dye. If you write to Merck, Jewell Street, London, E.C., you will be able to obtain it.

A QUESTION OF RIGHT.—I am anxious to obtain photographs of new Roman Catholic Church that faces up to the public street both interior and exterior, the opening of which takes place on Sunday next. I am asked to photograph the church and give donation to the fund in return for full copyright powers of same from the priest in charge, otherwise he will prohibit my selling same on the grounds that the church does not belong to the State but a private community. I shall be glad to know if the priest has any power to prevent me from selling photographs of the exterior, if taken without his permission?

AN ENGLISHMAN.

You have the right to do anything you like with the photographs.

"WANT TO KNOW," AND OTHERS.—In our next.

TONING BROMIDES.—1. What is the best toning bath for bromide for obtaining a rich brown-sepia colour? 2. I have been using a sulphide bath, bleaching with potass. bichromate and hydrochloric acid (carefully washing out all stain caused by bichromate, but generally tones have a yellowish tinge. Is this caused by metol-hydroquinone developer, and would ortol be an improvement? 3. Is potass. ferricyanide and amm. bromide of any use? If so, please give formula.—BROMIDE TONER.

1. The ferricyanide-bromide formula is about the best, and certainly the most convenient for commercial work. 2. We think the developer has little to do with the stain. Bichromate needs a weak bath of metabisulphite after it to discharge the stain. 3. Yes. See article on another page of this issue.

KINO.—Walter Carson and Sons, Grove Works, Lombard Road, Battersea, S.W.

CERAMIC PHOTOGRAPHY.—I should be glad if you could enlighten me as to the method of producing ceramic enamels, and if the carbon process is used in same, and, if so, how the transfer is effected on to the copper, as it seems to me the firing would dissolve the tissue. Is there any book issued on the process?—H. O. K.

Ceramic photographs have been done by the carbon process, but a special tissue is necessary, and it is not a commercial article. The process almost universally employed for ceramic photography is the powder process. A book on the subject by W. Ethelbert Henry and H. Snowden Ward is published by Dawbarn and Ward, Farringdon Avenue, at 1s. 6d.

. NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

EDITED BY GEORGE E. BROWN, F.I.C.

THE forty-fifth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,612 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1906 will also consist of 25,000 copies.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1906 will be modified to make it more than ever the book of universal photographic reference. The editorial article will deal very completely with the important subject of

PHOTOGRAPHIC COPYRIGHT,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The ALMANAC for 1906 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and wherever practicable new features of an informative nature will be added.

The text and advertisement pages of the ALMANAC are now in the printers' hands, and our publishers ask us to state that proofs of all matter are being despatched day by day, and should be returned with all convenient rapidity.

EX CATHEDRA.

Developed Prints on P.O.P.

The enfeebled light of the past few weeks has been sufficient to remind those who produce prints by any of the direct printing methods that still worse must be expected as the winter advances. A goodly number of photographers do not seem to be aware that P.O.P. prints which have had but a brief exposure in the printing-frame can be developed and, by this means, many times the number of pictures can be produced in a given time than would be the case if they were printed fully out in the first instance. The paper by Dr. Blacklock on another page describes a method of working which may be adopted for trial by those taking up the process, but we may add one or two comments suggested by his contribution. Of course, this method will not compete with bromide printing when time alone is the chief consideration. But there is a characteristic about a direct print on glossy paper that is not possessed by a developed bromide, and which a certain section of the public decidedly prefer. If this same character can be secured in a P.O.P. that has been but partially printed, and subsequently developed, it should be a great aid to professional photographers during the winter months. That the system is not very generally followed will be readily admitted, but there is no reason why it should not be, provided more attention were given to it than has hitherto been the case. It is really little, if any, more trouble than working in the ordinary way, as it is not absolutely necessary that the prints be toned. Certain agreeable colours are obtained by development alone, the precise "tone" being governed by the exposure the print receives in the printing. The more deeply the paper is printed, the warmer will be the tones; and, conversely the slighter the exposure to light the darker will be the tones, because more silver will be reduced upon the image by the longer development. It is scarcely necessary to say that the principle involved in the development of a P.O.P. print is entirely different from that of a bromide one. In the latter there is no free nitrate of silver present, in the former there is, and therefore an alkaline developer cannot be used for it; an acid one must be employed or universal blackening will result. Practically, the development of a P.O.P. is analogous to that of a collodion negative—the free nitrate of silver is reduced to the metallic state, and deposits on the parts acted on by light.

* * *

A Formula for P.O.P. Developer.

It is not our intention to recommend any particular brand of paper, or any particular developer for the work. Different papers behave differently, and so, in a marked manner, do

different developers so far as the tones are concerned at different stages, but we may say that with all the papers and different developers we have experimented with we have got satisfactory results, although the tones may have differed. Here is a typical developer that has answered well in our hands:—

Metol	5 grains.
Pyrogallol acid	5 grains.
Glacial acetic acid	2 drachms.
Water	10 ounces.

In place of the acetic acid citric may be used, and yields, with most papers, a colder tone. The prints must not be washed before development, as to do so would remove the free silver necessary to form, or rather strengthen, the image. In some of the directions for the development of P.O.P. prints it is recommended that the prints be transferred direct from the developer into the fixing bath, without previously washing them. This we look upon as being a mistake, as then the pictures will go into the hyposulphite in a strongly acid condition, and sulphur will be liberated in the paper. The reason why this method is advised is that the developing action would go on in the washing water, and the prints would turn out darker than was intended. But if the prints be put into a solution of salt and water all developing action is at once arrested, and the washing can be done at leisure when the batch has been developed. The fixing and washing of developed P.O.P. prints is precisely the same as if they had been fully printed in the ordinary way.

* * *

A Showcase Dispute.

A case of some little interest to photographers came before the Judge of the Wigan County Court one day last week, in which a photographer sued his superior landlord for £5, as damages for the alleged illegal removal of his show-cases from the entrance to the premises. It appears that the plaintiff took the business from another who had a lease of the premises, or such portion of them as was used for photography. In the lease there was no clause allowing show-cases to be put out, but the landlord gave verbal permission for that to be done. This permission seems to have been withdrawn from the plaintiff, who appears to be the tenant of the one who sold the business—the original lessee, and not the actual owner of the building. In the end judgment was given for the defendant, with costs. This case illustrates the necessity of persons, when taking premises, or taking over a business, to look carefully into the terms of the original lease when a sub-lease is granted, or an agreement made based upon it. In this case there was nothing mentioned about show-cases at the entrance in the original lease, only a verbal permission being given. In cases where show-cases are desired, they and their position and sizes should be specified in the lease; then there can be no disputes about rights. Such a clause usually exists in all leases where the tenant does not rent the whole of the premises.

* * *

Prices for Special Work.

We are frequently asked by photographers whose business experience is presumably limited to certain classes of work, what should be charged for some special or unusual work which has been placed in their hands. This question is always a difficult one to answer, as we can hardly ever be in possession of all the facts. The points, among others, requiring consideration are, how far will the work upset the general routine of business? What special expense must be incurred to do it properly? what is the

financial position of the client, and will he pay cheerfully, or will he complain if even a modest charge is made? As a rule, unless one specialises very distinctly it is not good business to decline a commission, but if there is plenty of the ordinary portrait work about, a price may be asked which if accepted, will pay the worker well. If the work is unusual or specially difficult there are other aspects. It may detrimentally affect one's business to decline a special commission under ordinary circumstances, for the inquirer will be likely to lessen his estimate of the photographer's ability; but, on the other hand, to accept and then indifferently execute such a commission has a very bad effect. There is, and can be no "usual charge," just as there is no uniform practice among surgeons to always ask the same fee for the same operation.

* * *

Preparing for Winter Business.

The dealers are now busy in introducing new designs for Christmas and New Year greeting cards to their customers, and very excellent some, indeed most, of them are. It not infrequently happens that photographers delay ordering their stock until the dealers have sold out the best designs. Those who intend to make a feature of these cards this winter will do well to secure what they require without delay. In this connection it is a little surprising that photographers rely so much upon the mount makers for the designs they use. Why do they not make original designs for their own pictures and print them with the portraits? The matter would be very simple to anyone with taste and a little skill as a draughtsman. The designs and lettering, ornamental or otherwise, could be made on cardboard, and then negatives taken of suitable size from them and used for double printing. The double printing, it is true, involves a little extra trouble, though not much, and the finished picture would be a departure from the "usual thing," and command a higher price. Will the portrait picture postcard, which has had such a run during the present year, and is being done at such a ridiculously low price, affect the Christmas portrait card business, and the prices obtained for them? We fear it will, to some extent, unless something in the shape of distinct novelty is forthcoming. An ornamental border got up by the photographer himself on the lines indicated would be a step in that direction, and no doubt prove a means of getting enhanced prices for the pictures, instead of only five or six shillings a dozen. The hint may be of service to some of our professional readers.

* * *

Children as Sitters.

The old order changeth. Twenty-five years ago the poor little mortal who was taken to the photographers was fixed in a chair of weird construction, and an iron head-rest pushed against his head, while many stern instructions as to keeping still and not spoiling plates were dealt out. Small wonder that the expression usually registered on the plate was such as may be seen in most family albums. How differently is the child handled now in some of the sumptuous palaces of photography. Yet we think the point is one of importance hardly sufficiently grasped by very many workers. Some photographers are, of course, quite unfitted by temperament for sympathetically handling children, and as a consequence do not get many to handle. Others have such a distinctive perception of the special methods necessary in any case, that children are always at their ease in the studio, and good portraits almost invariably result. The photographer needs to bear in mind several points as a basis of successful work. The modern child is usually more sensitive and highly strung, an inheritance largely the result of the greater tension required

in life nowadays. Rough treatment may be effective in keeping such children quiet, but the expression will inevitably indicate the treatment used. Then children of to-day have much more latitude allowed them. Three decades ago the rising generation were taught that they were to be seen and not heard; now, having brought up their parents better, they must earlier take a place in the table talk and the councils of the family. This undoubtedly produces a feeling of independence which must be reckoned with. Another most important point is to estimate the mental power of the little sitter. No one is more ready to resent an insult to the intelligence. Special care should be taken to guard against undue familiarity of treatment, a rather dignified courtesy, if kindly, being much more effective than anything in the nature of "gush."

* * *

Disputes as to Payment.

The recent case heard at the Westminster County Court, in which Mr. Kubelik's manager was sued by a poster artist for £25, the value of a poster design—the amount claimed was awarded to the plaintiff—is an interesting one for photographers. While we should strongly advise meeting clients as far as possible, professional photographers undoubtedly find a number of people whom nobody can satisfy, and who will, on the slightest pretext, refuse payment. We make no comment whatever on the Kubelik case, but the decision of the jury, who were, no doubt, instructed in the various points of law involved, and who applied ordinary business common-sense to the case, clearly goes to show that where an order for artistic work is given, payment in due course must be made, whether the result is considered perfection or not. If it can be shown that the artist, whether photographic or other, has reasonably carried out the expressed wishes of his client, the contract will usually be regarded as fulfilled. It is manifestly impossible to submit an exact sample in cases where an original artistic work is being produced in the same way that a sample of a manufactured article may be shown. The purchaser exercises his discretion in selecting the man to whom he goes. In the case referred to the question of likeness was raised, and here, of course, uncertainty often arises. It is a matter of every-day experience that portraits are produced which some of the sitter's friends think excellent likenesses, while others equally intimate with the sitter regard them as poor. Another point—where a photographer advertises "satisfaction guaranteed" he has little or no claim to his money in case of dispute, and it will, we think, be found that where these words occur in circulars or price lists, "cash at time of sitting" is a fairly rigid rule, thus making it necessary for the initiative in any County Court proceedings to be taken by the dissatisfied customer.

* * *

Temperature of the Dark-room.

In our last issue various methods of heating the studio were referred to, but an equally important point, during the winter months, is the warming of the dark-room. Unless its temperature is maintained the comfort of working, and the results obtained, will suffer. If the temperature of the room falls much below 50 deg. F. the negatives will develop slowly, much as if they had received but insufficient exposure, and there may be a difficulty in obtaining sufficient density or vigour in them. It is true that the solutions, as well as the dishes, may be warmed, but that is only a partial relief, inasmuch as they quickly cool down again when used in an abnormally cold place. Therefore it is best to have the means of artificially warming the

dark-room during the winter months, alike by day and by night. Dark-rooms being usually by no means large, a very small amount of heat will suffice to keep them at a proper working temperature. A small gas stove would suffice, if it were furnished with a flue to carry the products of combustion outside, for to allow them to escape inside would be very injurious to the health of the worker, and further, as we said last week in reference to heating the studio with gas, much of the heat is wasted.

* * *

Paraffin Stoves for the Dark-room.

On the whole, perhaps, the best and most economical method of warming the dark-room is by means of paraffin stoves. They cost but three or four shillings, and one with a three to four and a half inch wick will serve to keep an ordinary dark-room at a suitable heat throughout the day, provided the door is not left open more than is necessary. If placed on the floor the light from it should cause no inconvenience, and the heat will be pretty equally diffused throughout the apartment. A common paraffin lamp, with a three-quarter or an inch wick, left burning, will suffice to preserve the room and its contents warm throughout the night, and prevent water in the taps from freezing. It is surprising to those who are not aware of the fact that a small source of heat is required to keep a small room warm when the door is kept continually shut. An objection may be raised to paraffin as a source of heat on account of smell. But there need be little, or no, smell from paraffin stoves, or lamps, if the parts be kept clean and the wicks properly trimmed. If these points be neglected, the lamp is liable to give off unpleasant fumes, but unpleasant as they may be, they are unlike the emanations from burning gas in their injurious effect on health or photographic operations.

THE CAPABILITIES OF MODERN LENSES.

PHOTOGRAPHERS who have a good deal of landscape, group, and architectural work to do in addition to the usual portrait sittings in the studio are now buying the modern type of anastigmatic lens for the purpose, and in several cases which have recently come under our notice have expressed disappointment after a few trials with the instrument. In every case this has arisen from a failure to appreciate the special points wherein the anastigmatic lens with a flat field differs from its forerunner, the rectilinear, or symmetrical. To put the whole matter in a nutshell, speed is the only point gained by using the modern lens. A good symmetrical or even a cheap French R.R., costing, say, a sovereign for a whole-plate size, will give a picture with critical definition if it is stopped down to perhaps $f/22$ or $f/32$. The anastigmat will give equal sharpness at its open aperture of $f/6$ for all objects situated in the one plane. Suppose a photograph is required of a bill-poster's hoarding. The camera is set up exactly opposite and the image focussed with an R.R. lens at $f/8$. The image on the centre of the focussing screen can be got sharp, but the original image will be more or less blurred owing to astigmatism and curvature of field. To secure sharpness the lens is stopped down, the diaphragm correcting the blurring, but only by reducing it, and of course at the expense of speed in exposure. If the R.R. be now replaced by an anastigmat and focussing is performed at the open aperture, it will be

found that the whole of the image of the hoarding is sharp both in the centre and on the margins of the plate, and no stopping down will be necessary. The flat hoarding constitutes an object all in one plane. In group work we have a close approximation to the same thing, the figures being all nearly the same distance from the camera. Here the flat-field lens will often enable an exposure of a quarter-second at $f/8$ to be given instead of the two seconds required by an R.R. stopped down to $f/22$ to secure sharpness of the outside figures. All photographers who do much group-photography will at once recognise that this constitutes a great advantage. So in architectural work, the main portion of the view may be a building which alone is the important object. Other more distant objects are not essential, and the effect will be better if they are diffused in the photograph instead of being sharply defined. An R.R. must be stopped down until marginal definition of the main object is secured (for exactly the same reasons as in the case of the hoarding), and then it frequently happens that this stopping down gives the distance sharper than is desired. The anastigmat may perhaps need the second stop to give enough depth of field to include the main object from its nearest to its furthest point, but at that aperture the more distant objects will generally remain softly defined.

Turning now to the cause of dissatisfaction, let us assume a landscape with objects as near the camera as 30 ft. and as distant as half a mile, all of which are required quite or approximately sharp. Let us further assume that the images of both the near and the distant

object fall about the centre of the ground glass. Focus the near object, with the R.R. lens, at an aperture of $f/8$, and it can be got sharp. So also, by racking the lens a little nearer to the ground glass, the image of the distant object can be obtained sharp. But in no position of the focussing screen will both objects be really sharp at one and the same time. Replace the R.R. lens by an anastigmat of equal focal length, and precisely the same result will be noticed. In this respect there is absolutely no difference between the one and the other. If near and distant objects are required sharp at the same time the lens must be stopped down, and the greater the focal length the smaller must be the relative aperture used for such subjects as the one we have just assumed. It is ignorance on this point which leads to so many complaints as to the performance of magnificent lenses, and probably to a good deal of the dissatisfaction which is expressed.

It should be noted that, although we have said that no lens will sharply define objects 30 ft. and half a mile distant from the camera at the same time, in actual practice small lenses of, say, 4 in. focal length would give images so nearly sharp as to be considered sharp enough for all practical purposes. In hand-cameras provided with lenses of 4-in. or $4\frac{1}{2}$ -in. focus it is possible to secure negatives with all objects beyond about 20 ft. sufficiently sharp. In the case of lenses of greater length of focus the difference in definition is very apparent, as the worker soon finds out when commencing to use a 15 by 12 camera after being accustomed to a quarter-plate or half-plate instrument.

THE WEEK IN HISTORY

Daguerre and Niepce.

THE partnership between Niepce and Daguerre was approaching actuality in October 1829. It came to pass on December 14 of that year, but we get a glimpse of the preliminary state of things from a letter of Niepce to Lemaitre dated October 25. It shows his first disposition to part with his knowledge to Daguerre, and proves also his reversion from a photo-engraving to a photographic process, using these terms in their modern significance.

"You are under the impression that my plate is engraved. It is not. It is only blackened, without using acid, by a process, my own unskilfulness in the use of which has given me little success, the black depositing on the least pronounced parts of the print. Hence I have been obliged to remove it as well as I could with very soft linen. My object was to obtain all the gradations of black and white on this silver plate, and I think that with greater care and skill I shall be able to make good use of this process. You were right in attributing one of its striking defects to its long exposure. Unfortunately, it is impossible to avoid this. . . . In order to obtain success the exposure must be short, i.e., the image must be sharp and brilliant. For this a camera as perfect as M. Daguerre's is necessary, and without it I fear that I shall be only partly successful.

I am, therefore, anxious to reply to his proposals, and to invite him to co-operate with me in the perfection of my heliographic processes, and to share in the benefits which will spring from our complete success. I have told him that by making the same offer to yourself I should like to find an additional guarantee of success in the utilisation of your "good talents."

To this Lemaitre replied that Daguerre had greatly improved the camera and mode of using it, and that no one could better co-operate with him in the development of heliography. Daguerre,

he said, did not favour the idea of working for an engraving process, but was anxious for Niepce to devote himself to the perfection of the process apart from this.

The First Negative Albumen Process on Glass.

One of the classics in the early history of photography is the paper by Niepce de St. Victor, read before the Paris Academy of Sciences exactly 58 years ago. On October 25, 1847, he described the process by which he applied the sensitising processes of Talbot to glass plates by the aid of a film of albumen. He was a follower of Sir John Herschel in the matter of using a rigid glass plate instead of paper as a support of the sensitive film, but he modified Talbot's procedures in giving effect to his ideas. His albumen process on glass marks the divergence of the stream of progress into a new channel. From that time forth the current of work was towards glass as a support for the negative, although it must not therefore be assumed that then or in any period of the history of photography the sworn adherents of paper or other flexible negatives have been non-existent.

Niepce de St. Victor prepared his sensitive film by beating up albumen with potassium iodide, potassium bromide, and common salt. This mixture he poured on his glass plate, which he heated until the albumen hardened and became insoluble. He then sensitised the plate in silver nitrate, and exposed it either wet or dry. Development followed in a solution of gallic acid. The process was in general practice in England up till 1850, and perhaps the fine architectural work done by Ross and Thomson of Edinburgh may be within the knowledge of some of my readers. In fact, I believe Levy, of Paris, the successor of Ferrier, still employs a modified form of it for his exquisite lantern transparencies.

HISTORICUS.

PHOTOGRAPHIC SOCIETIES AND EXHIBITIONS.

SOME NOTES ON THEIR PRESENT POSITION AND MANAGEMENT.

VI.

Members' Lantern Evenings.

In the last article (page 786) mention was made of the lantern shows that figure so prominently in the winter programmes of most societies. In many instances these lantern nights are nothing more or less than what have been described as "peep-shows." Series of slides are projected on to the screen—sometimes accompanied by brief remarks and sometimes in silence broken only by the whispered comments of the assembled members. This type of evening should be abolished. No good purpose is served, especially when only the titles of the slides are read out, and the proceedings are generally very tame and uninteresting. They should be made both interesting and instructive, and this can be achieved by announcing that criticism both from the artistic and technical standpoint will accompany each slide. This criticism should be supplied by the members themselves or at least by a few who are qualified to criticise. Technical data concerning the method of a slide will probably interest a much greater portion of the members at this time of year than a long description of the place portrayed. Particulars of exposure, development, toning, etc., should always be given when available, and this can easily be obtained if the slides are by members. A discussion regarding the merits and faults in composition or technique, and suggestions for remedies, while the slide on the screen will prove of great advantage to everybody concerned, and, moreover, can be more easily accomplished than criticising a print which only one or two can inspect at a time. Lantern evenings of this description should therefore, whenever possible, take the place of the lantern show where the slides are simply jerked through the lantern with little or no comment, and will amply repay any extra trouble taken in organising them.

Lantern Lectures.

A certain amount of preparation is always necessary to make a lantern evening a success apart from the subject of the lecture and the personality of the lecturer. Nothing is more disconcerting to the average lecturer, no matter whether he is a member of the society or a visitor, than to arrive on the scene and find a goodly audience, but no preparations made for his comfort. The capable secretary should ascertain beforehand if the lecturer requires any special appliances, and in addition should always have ready a reading desk and shaded lamp, which may sometimes be necessary when the lecturer has notes. A reliable method of signalling between lanternist and lecturer should also be arranged, as nothing is more irritating to an audience than a knock on the table or floor or other noisy signal to change the slide. A small clicking instrument sold for the purpose is better, and an electric communication with muffled gong is best. Failing this, however, a signal by means of a small red light in the back of the reading-lamp, placed so that it can be easily seen by the lanternist, is satisfactory and silent. Every society should, nevertheless, if many lantern lectures are to be included in the programme, invest in one of the electric signals. They are not expensive, and their utility is unquestionable. The lantern, too, should always be in readiness, and a slide focussed before the advent of the audience. Matters will go much more smoothly if this precaution is seen to. The arrangement of the chairs on visitors' nights, when a lantern lecture is on, is a duty that devolves on the "stewards" previously mentioned. It is a small matter, but one that receives very little attention as a rule. The front chairs should not be placed too near the screen, especially if a large picture is projected, as such close proximity is not good for the comfort of those in the front row, or for the enlarged

slide, which will not appear to best advantage under such conditions. A central gangway should always be kept, and the lantern itself should be isolated; and lastly, when arranging a lantern lecture, see that it is not too long, or the audience will become wearied, no matter how good the material may be.

Interchange of Lectures

When it is found that a member is capable of giving a good lecture or demonstration, his consent should be obtained, and the secretary should endeavour to arrange an exchange of lectures with other societies who may also have "show men." This is one of the chief attractions of the various federations and unions in different parts of the country, and is, of course, also one of the principal features of the R.P.S. Affiliation. In addition to sending out "ready-made" lectures, the Affiliation publishes a list of society members who are willing to lecture at other affiliated societies in exchange for lectures for their own club. This interchange of lectures should therefore be worked as much as possible, as it not only brings in new and interesting lectures and lecturers, but also indirectly serves as an advertisement for the society.

The Portfolio Section.

Every go-ahead society should have a portfolio section. This should be conducted on the lines of the well-known postal camera clubs. Every member who is capable of producing a print, and takes any interest in the progress of photography and the society, should be inveigled into joining the section and circulating his pictures. The mistake is frequently made in large societies of having a "beginners'" and an advanced portfolio. This should not be so, as the beginner is the very individual who should be encouraged, and who is most likely to profit by seeing the work and having the criticisms of the more advanced members. True, the advanced member may possibly object to having his work criticised by the beginner, which is very likely to happen, but even then, a wrinkle is occasionally gleaned from some such outspoken remark, and, moreover, the member who thinks his efforts too "big" to be included in a mere society portfolio is far better out of it. Care should be taken, however, by the secretary—or portfolio secretary—to watch the criticisms and at once suppress any tendency to personalities. This form of comment has killed more than one promising endeavour of the kind. The example of good criticism by a strong worker in the club will "set the pace," and do much to indicate the lines on which the criticism should be given. A note-book is also a useful part of the circulating portfolio, and in it photographic matters of technique can be discussed, or a subject for discussion can be started for each round. The members' opinions can thus often be sounded better than at the open meetings. It may be argued that in societies with a large membership—of which more than, say, thirty, will participate in the circulation of the portfolio—the matter becomes unwieldy on account of its size. Each member will want to keep the book at least a couple of days to observe and criticise the prints before sending on to the next member, and this means, with thirty members, a space of three months before a contributor will see the remarks made on his work. This difficulty can be met by having several portfolios running concurrently, each with a membership of, say, twenty, and each in charge of an advanced worker. If these circulate with regularity—and punctuality is essential for the success of the scheme—as many as a dozen folios can be circulating at one time, and each member can depend on seeing at least one a week. The interest is thus not allowed to flag, and if, in addition, the books are brought by the members to every meeting where there is a

possibility of displaying them, a lot of healthy rivalry will be engendered and better work result.

Survey and Record Sections.

Apart from the pictorial and technical members of a society, there are usually to be found a few who are interested in survey and record work. The secretary should endeavour, if he can excite the interest and enthusiasm of these few, to form a section devoted to this speciality. A sub-committee should be formed to map out a district to be systematically photographed and the photographs preserved. The curator of the local museum will probably afford much useful information, and every item of archaeological interest in the district or locality decided upon should be carefully marked down for attention.

The neighbourhood can be either divided into sections, and each member who is willing allotted a section, or each member can be asked to undertake certain subjects—such as the churches, landmarks, old houses, local customs, etc. At all events, the formation of a survey section will afford many members of the society an object to work for, and as the undertaking will usually never be entirely completed, the interest can be sustained indefinitely. If arrangements are made to exhibit the record and survey photographs, permanently display them in the local museum, or hand them over to the National Record Association for storing in the British Museum, a good and educational purpose is being achieved, and a lasting advertisement made for the society.

"HON. SEC."

RAPID PRINTING AND DEVELOPMENT OF P.O.P.

[The following paper, read before the Gateshead Camera Club, on Wednesday in last week, touches a branch of work which usually obtains prominence at this season of the year. Though the method of developing faintly printed P.O.P. is by no means new, satisfactory formulæ are not numerous, and judging from the prints sent to us by the author of the present communication, Dr. Woolsey Blacklock, the process recommended by him should repay a serious trial.—Eds., B.J.P.]

GELATINO-CHLORIDE paper, commonly known as P.O.P., is probably used by more workers, and in greater quantity than all the other photographic printing papers put together. The makers would be justified in adding another P. to the name, making it P.P.O.P., or popular printing-out paper. It is the easiest to use, and the easiest to fail with, and though its price is low, the average cost of each finished print is high. This is due partly to the use of gold in toning, but principally to the large percentage of prints that are wasted in the practice of the ordinary amateur. Over-printing, under-printing, over-toning, under-toning, double-toning, and high-lights that are bright yellow, pink, or brown, instead of being white, are some of the many causes that lead to the filling of the waste-paper basket with spoiled prints, each of which has cost as much for time, trouble, and material as the most successful prize-winner of the lot. The process I am about to describe is free from most of these difficulties. The time of exposure is considerably reduced, and the question of over-exposure or under-exposure rendered unimportant; no gold is used, therefore the cost of that expensive metal is saved, and the numerous evils that accompany its use are thus avoided. The principal advantage of this process is that it enables the worker to produce a series of uniform prints with rapidity, certainty, and the minimum of waste.

The saving in time is very great, one-sixtieth of the usual exposure being quite sufficient. This is shown by exposing strips of P.O.P. to light for gradually lengthening periods, and comparing the results before and after development. The experiment may be described thus:—A piece of P.O.P. $4\frac{1}{4}$ in. by $3\frac{1}{4}$ in., is taken from the packet, and a strip $\frac{1}{2}$ in. wide at one end of it is covered with a piece of card, and the remainder exposed to daylight for 30 sec. Another $\frac{1}{2}$ in. is then covered, and the rest is again exposed for 30 sec. A third $\frac{1}{2}$ in. is covered, and another exposure of 1 min. given; then a fourth $\frac{1}{2}$ in. is covered, and the remainder exposed for 2 min. A fifth $\frac{1}{2}$ in. is covered, and an exposure of 4 min. given. Then, after covering the sixth $\frac{1}{2}$ in. an exposure of 8 min. is given, and lastly, the seventh $\frac{1}{2}$ in. is shielded and an exposure of 16 min. given to the eighth. The first $\frac{1}{2}$ in. has not been exposed to light, while the others have received exposures of 30 sec., 1 min., 2 min., 4 min., 8 min., 16 min., and 32 min. respectively. The sheet is then cut in halves lengthways, and one half developed and fixed. On comparing them it will be found that the second space on the developed half, which had been exposed for 30 sec., is as dark as the last strip on the other, which had been exposed for 32 min. This gives a proportion of 1 to 64, and shows the saving in time resulting from using the developer. This increase in sensitiveness

involves scrupulous care not to expose the paper to light when placing it in or removing it from the printing-frame, or when examining it to ascertain the depth to which it has been printed; any error in this respect will be shown by a corresponding darkening under the influence of the developer. Therefore it is better to develop by artificial light, such as ordinary gaslight; a yellow screen is not necessary.

The developer is made in two solutions:—

A.

Pyrogallie acid	32 grains.
Tartaric acid	32 grains.
Water	16 ounces.

This solution will keep for three or four weeks.

B.

Potass bichromate	1-16 grains.
Water	16 ounces.

This solution will keep for several months. The easiest way of making it is to make a stock solution, 1 gr. to 1 oz., and add $\frac{1}{2}$ drachm of it to 16 oz. of water.

Equal parts of A and B are mixed immediately before use, and will develop two or three prints in succession before becoming discoloured.

The prints are immersed dry, just as they come from the printing-frame, care being taken to see that the surface is uniformly wetted, and that there are no air-bubbles. Development begins in about a minute, and is allowed to continue until the print is about as dark as the finished print is wished to be. It is then removed, washed quickly in water and placed in the fixing bath. No time must be wasted in doing this, as the print darkens with increasing rapidity. Fixing bath: Hypo, 1 ounce; acetate of lead, 60 grains; water, 6 ounces. The prints lose very little in this bath, and are of a fine sepia tint. The depth to which they should be printed in the frame may vary within wide limits. A faint image, showing only the deepest shadows, is sufficient, as the developer will bring out the rest of the picture. If printing is carried farther there is less for the developer to do. It has appeared to me that the printed part of the picture loses more in fixing than the developed part, therefore I prefer a faint print to start with. Bichromate of potassium was mentioned as an accelerator in "The British Journal Photographic Almanac" about ten or fifteen years ago, but the solution recommended discoloured very rapidly, and stained the prints. Acetic acid prevented this, but made the gelatine too soft. Tartaric acid was found to be more suitable.

A. WOOLSEY BLACKLOCK.

LETTERS TO A MIDDLE-CLASS PROFESSIONAL.

IV.

OBVIOUSLY, an absolutely plain board is not calculated to make a pleasing mount, so the next item on the programme is the description and surrounding for the print—whether it is to be plate mark, and, if so, of what description; a paste-down tint, and, if so, of what colour; a litho'd border from block, decorated or otherwise; or a ruling in colour. In spite of all that has been said against the plate mark (slavish imitation, etc.), I believe strongly in it, for certainly it is the least obtrusive and most generally useful surround, for if we introduce paste-down tints, coloured borders, etc., to mounts we are further curtailing the adaptability of that mount to varying circumstances. Moreover, one of the greatest booms of the plate mark appears to be overlooked, for, when well sunk, the raised border protects the sunk print from scrubs and scratches of other prints placed upon it.

The paste-down centre appears to have outlived its previous popularity, though I should not be surprised if it once more comes into vogue, since it strongly resembles the multiple paper mount. A general rule for the tints of paste-down can hardly be given, though, perhaps, it may be taken that either the mount or paste-down should harmonise with the print, or the paste-down centre with the mount. These centres in the past have usually been applied to white mounts. The latter being practically neutral, the centre should follow the general rules of harmony or contrast laid down in my last—we use grey on white for plats, and brown on white for warmed-toned prints. These mounts, you will observe, have all the defects of a plain white mount without their adaptability for numerous coloured photographs; for this reason I do not advise you to use them.

Plain rulings round the print are very good, especially if care be exercised in the choice of inks. Of course, I do not advise the old red ruling of the Oxford mounts, but for grey mounts a single or double line, either in black or white, is very effective. Not many makers have the blocks, but if you wish to get away from the old plate mark, and plate marks are not good on dark mounts, it would be worth while to get them specially made. A set for four cabinet shapes in brass costs about £2. To deviate a little, the name and address should be in black when using the black rule, and in white when using the white line; the edges in the latter case should be white, and in the former white, or same grey as mount, or black. For plate mark it is usually advisable to have the lettering blind blocked (plain stamped), and the edges same tone as mount.

The position for the print on the mount must now be considered. Very few prints look well when placed in dead centre, a dropped appearance being apparent, as if the print was below centre of mount. It is therefore advisable invariably to have the print well above the centre. In the case of 11 by 8 board with ordinary cabinet centre, an inch more margin at bottom than top will not be too much. About the same measurement will do for the other shapes, allowing even more at bottom for the circular cabinet. It is better, however, to keep the margin at sides equal, though not necessarily

equal to space above print. In very few cases do prints look better with more space at one side, and it is certainly not worth while stocking for them. Of course, with this greater space at foot of mount, for horizontal or "view" pictures another mount is necessary. The mount is usually also "view" way, and the rule for space at bottom again holds good. Some of the newer mounts, however, have the plate mark view way, but retain the upright type of mount. There is a great deal of space at bottom, less at top, and little at the sides. This gives an individual, but not an eccentric mount.

As I said above, the exact place for plate mark or other centre is important, and working drawings of your idea should be supplied.

I have already touched lightly on the name and address, which may be in the various types or in signature form from a block. I strongly advise you to stick to a signature form of name, and use it on all memos, letter heads, mounts, and ads. It gets known, and is distinctive. To quote a case you probably know well is to speak of the enormous use made by Boots, the chemists, of their signature. An alternative method is to have the name lithographed. When this is done the name and address are usually placed at foot of the plate mark or paste-down centre. For grey prints have black ink, for warm tones brown, or, in case of veillums, red may be used. Blind blocking is, however, the most useful method of attaching the name, and cannot help but be suitable, except, perhaps, with the line 'mounts mentioned above.

The position for the signature block when used should be decided with care. Never place dead in the centre of mount. Either to right or left hand side. The right is the more usual place for signing a picture. When there is much space below the print the signature serves to break it up, and is useful for balancing the whole.

We at length come to the last item, the edges—whether plain cut, plain bevelled, or colour bevelled. All this is a matter of taste. For white mounts either of the first two methods are indicated, and not the last. Plain cut is cheapest, and the only method necessary or desirable if the mount is to go in a folder. Cream mounts seldom want the edges colouring. Dark mounts may either be coloured same tint as board or of a colour to suit the name stamping on centre surround of print.

To conclude this letter, my latest thing is a six-sheet cream or white board, plain plate-marked, plain blocked, and plain cut edges, placed either in a grey or, in the case of cream mounts, a brown folder (same colour as prints). These folders have the name stamped in ink of the same colour, but of a lighter tint than themselves.

The great convenience of a universal outside size is greatly felt, and much time hitherto spent in finding right size folder is now saved.

I would mention that I purchase my folder covers and mounts separately, slipping in myself, not being dependent on the ready-made folders that are generally supplied.—Yours, STUDIOSUS.

FOREIGN NOTES AND NEWS.

A Word of Acknowledgment.

EDER's "Jahrbuch," reviewed recently, is the source from which the notes on this page are quoted, with the exception of the last paragraph, which appears in several Continental journals.

New Focussing Rules for Hand-Camera Work.

Prof. Pfundler, after treating of the subject from a mathematical point of view, gives the following two simple rules for focussing, which may be useful to hand-camera workers:—1. (Applicable when

the background is not very distant) Focus on a distance equal to twice the product of the greatest and shortest distance, divided by their sum. Example.—Suppose the subject to be a street scene, with a house front twenty yards away and a man five yards away, and that both are required sharp, then $(5 \times 20) \div (5 + 20) \times 2 = 8$ yards, the required point to focus on. 2. (Applicable when the background is infinity) Focus on a point just double the distance of the nearest point. Example.—Again assuming that the nearest

point is five yards, then $2 \times 5 = 10$ yards the point to focus on. To find what stops must be used to give an error of confusion not exceeding 1-250th of an inch, the rule is: Multiply the allowable error by the focus and divide by the distance focussed on minus the focus, all measurements to be in inches.

Rapid Chloride Emulsion.

Lüppo-Cramer has endeavoured to obtain silver chloride emulsions as rapid as bromide. Finding that the usual method with ammonia caused fog, he used the following formula:—

Gelatine	10 gms.
Salt	7 gms.
Hydrochloric acid (sp. gr. 1.9)	10 c.cs.
Water	160 c.cs.

Heat to 176 deg. F., and add

Silver nitrate	10 gms.
Water	100 c.cs.

also heated to the same temperature. The emulsion was boiled for a quarter of an hour, and then treated as usual. A homogeneous emulsion of fairly fine grain was obtained, and the speed was about three times that of the commercial chloro-bromide emulsions.

More About the New Cyanines.

Von Hübl has examined the absorption and sensitising spectra of the old and new cyanines, and comes to the following conclusions:—
1. Aqueous and alcoholic solutions of the cyanines contain the dyes in a different form. They can be distinguished by their colour, for the aqueous solutions are always more reddish than the alcoholic, and, further, aqueous solutions will run almost colourless through a filter. The different colour of the solutions is not due to difference in dispersion of the solvent, for both solutions show the same absorption bands in exactly the same places, but their intensities are different. The difference is noticeable when the dyes are in solid media, and it is possible to distinguish whether they have been precipitated from aqueous or alcoholic solution.
2. The sensitising powers of the cyanines correspond to their absorption spectra in the solid state. As in gelatine plates, the β -band predominates, the minimum between this and the individual sensitiveness of the plate is smaller than with collodion. The displacement of the two bands by about 100 Angstrom's units can be explained either by screening action, or one must assume that the dye reacts chemically with the silver bromide, and that a coloured substance with another absorption spectrum is formed.
3. The disappearance or lag in sensitiveness corresponding to the α -band appears to be connected with the absorption spectrum of the dye adhering to the silver bromide. With reference to the "bands" mentioned above, it is as well to point out that von Hübl finds that in aqueous solution the cyanines

show absorption bands, the strongest of which lies about λ 560. This he calls the β band, whilst in alcohol the strongest absorption lies nearer the red by a few wave lengths, and this he calls the α band.

Dicyanine.

Von Hübl has examined a new dye, just prepared by Meister Lucius and Bruning, which presents some distinctly new features. It has hitherto always been assumed that chinoline was necessary to form cyanine, but this new dye possesses no chinoline ring, but two lepidine rings, and has been named as above by Dr. König on this account. In alcohol the dye gives a dirty-blue solution, in water a dirty-red solution. The absorption in alcohol shows two bands— A_1 maximum at λ 600, A_2 maximum at λ 560 and in water one band with the maximum at λ 520. The sensitising of this dye extends from F right beyond α in the infra red of the spectrum. This is the most energetic red sensitiser yet known.

The Action of Bichromates on Gelatine.

Since the classic researches of Eder on the action of the chromates on colloid matters in the presence of light, practically no work has been done on this subject, but the subject has recently been taken up by MM. Lumière and Seyewetz. A paper by them was read at the International Congress of Photography, held at Liège from July 19-24, but has only, at this belated hour, made its appearance. It is unnecessary to follow the experiments throughout, but the conclusions come to are as follows:—
1. Bichromated gelatine rendered insoluble by the action of light contains chromium sesquioxide ($Cr_2 O_3$) and caustic potash. The latter forms, with the excess of bichromate, the less sensitive neutral chromate.
2. This gelatine differs considerably in its composition from that which is tanned by the chromium oxide salts. The oxide of chromium, which it contains, appears to consist of two portions—the one portion is constant, and corresponds to 3.5 per cent. of the chromated gelatine. It is comparable with the oxide, which the gelatine, rendered insoluble by the chromium oxide salts, retains. The other portion varies with the duration of the exposure, and is produced by the reduction of the bichromate by the organic substance in light.
3. The quantity of the chromium oxide, which is retained by the insoluble gelatine, increases with the duration of exposure, but not in proportion. This increase becomes weaker and weaker in proportion as the quantity of the neutral chromate increases.
4. The decomposition of the excess of bichromate by the chromium sesquioxide appears to be only partial, as stated by Eder. On account of the instability of this substance, an analysis can give no accurate conclusion as to its composition.

HOW A STUDIO WAS ADVERTISED.

[The following article, describing the scheme of management of a New York portrait studio, whereby prices were doubled and business raised to large proportions, appears in a recent issue of our advertising contemporary, "Printers' Ink." In reprinting it, we may recommend a careful perusal of the lines on which the Benedict studio was brought before the public. The booklet method which was employed is a form of advertisement which cannot be indiscriminately applied to any and every business, but there are some other suggestions in the article which may be of profit to professional photographers in this country. We shall take the liberty of reprinting in an early issue the article by which the organisers of the Benedict business were led to speak of their methods.—EDS., B.J.P.]

FOR a number of years the Siegel-Cooper store, New York City, has had a photograph gallery upon its top floor, but until three years ago it had always been conducted on the bargain principle. The average price of cabinet pictures was \$1.50. Three years ago a change of management was made and the gallery put in charge of James L. Acker, who had been with Frederick and Dupont, well-known New York photographic portraitists. Mr. Acker set to work to raise the character of the gallery's patronage, and in a few months by means of advertising and a general bettering of standards, had increased the average price of its product to \$3 per dozen,

while portraits costing as much as \$10 are now made in what was formerly a department store adjunct.

In "Printer's Ink" for May 24 appeared an article on "Advertising for the Photographer," containing general principles so sound, in Mr. Acker's opinion, that he submitted specimens of his own advertising and consented to tell something about his methods in a field that has heretofore been singularly dormant in publicity.

The Advertisement Which Costs Nothing.

"A" photographer has one great advertising medium that costs him nothing at all," he began; "that is the privilege of putting his

name and address on every picture he makes. A dozen photographs will ordinarily be distributed among at least eleven families. They will be preserved for years, and when their possessor wants photographs a common proceeding is to examine the pictures in his collection and take the address of the man whose work is most impressive. To use this advertising medium to the best advantage the photographer must do good work, first, and after that endeavour to attract the best class of trade, so his work and name will be known among the people who have the most money to spend.

"This gallery was formerly known as the Siegel-Cooper gallery, and the store's imprint appeared on all work. We adopted the name 'The Benedict Studios,' giving the gallery an independent standing. It is entirely separated from the store proper. A cheap class of work had formerly been sought, and this we set about to change also.

Avoid Cheapness as an Inducement.

"It is a strange tendency that leads photographers into price competition when they advertise. Nothing could be more unfortunate than price competition in this business. For years and years the crayon enlargement man has travelled from door to door lowering the artistic tone of photographic portraiture. Frequently his function has been assumed by the downright swindler who collects a nominal advance payment from unsuspecting persons and disappears with a valued photograph. Competition has always been the advertising resort of cheap photographers. A favourite method is that of distributing coupons which entitle the possessor to a discount on a dozen portraits, or to a large portrait free. Methods of this character have lowered photographic advertising to a level where out prices or the price appeal stand for cheap work. So the thing to avoid first of all is the bargain argument.

The Wording of a Booklet.

"I wanted to reach a good class of people in advertising the Benedict Studios. I knew that artistic portraits could be made at \$3 a dozen. Newspaper advertising in New York City covers too wide a field for my purpose, so the mailing list was adopted. Our first piece of literature was a booklet on 'Photography as a Fine Art.' This gave half-tone examples of good portraiture and dealt with the personal equation in photography. This excerpt gives an inkling of its style:—

"In portrait photography it is, of course, highly necessary that all conditions be favourable—modern cameras, properly arranged skylights, and ample studios, and all the other various photographic paraphernalia play an important part in the final result. Yet, behind and above all this, is the skill of the artist. The artistic value of a photograph, its power to portray a likeness, to make you see, not only requires all the modern mechanical means, the greatest skill and experience, but those subtle, intangible qualities that lie down deep in a man's make-up and which we conveniently term the "artistic sense."

"Many folks look upon the camera as a mechanical device which is simply to be "snapped" and that will always produce the same sort of picture. But how different will be two portraits made by the same camera but by different operators? One merely a picture—cold, flat, lifeless; the other glowing with a personality, suggestive in pose, or with possibly some pleasing and familiar emphasis of feature—a masterly use of light and shadow; in short, such a true "characterisation" of the individual that under the recognition of your friendly eye it seems fairly to take life. And this is photography—photography as a fine art."

"Views of the gallery, reception and dressing rooms were also printed, with something about enlargements and harmonious frames. Fifteen thousand copies were mailed to names taken from the Elite Directory and telephone book. In the former I selected names of people who would not be likely to patronise the more expensive

famous galleries in New York, and in the telephone book those of people living in the suburbs. The returns were excellent. People came and brought children to be photographed, and when they were once in the gallery we made portraits of the mothers and all the children, depending on artistic work to sell several times the number of pictures that were wanted. This is where the value of advertising lies in the photographic field, for the photographer's chief difficulty is to get people into his gallery. Once under the skylight, with a skilled, tactful operator, it is easy to secure orders for several dozen portraits—provided, of course, the bargain-hunting element has been eliminated. Last week, for example, a mother brought a baby in to have a single picture made to be sent to Europe. One of our operators photographed two older children while the mother was in the dressing-room, then photographed the baby and herself. The result was an order for five dozen pictures. The advertising photographer should never limit the number of exposures if he knows his business.

Children are the Photographer's Business Bringers.

"Children are the key to the whole family in photographic advertising. Get a child into the gallery and the family follows. For this reason our second booklet was entitled 'Photographs of Childhood.' It gave examples of portraiture in this branch of work, and dealt almost wholly with the elements of personality, sympathy with the little sitters and the need for portraits at a time of life when children are growing and changing. Here are some selections:—

"It might be said that the successful photographer of children, like the poet, must be born. Certain it is that no amount of technical training can take the place of that natural sympathy that must exist between the man and the child, if the highest ideals of portraiture are to be realised. Children act by impulse and intuition, and are alike quick to repel and respond to the influence of the photographer. A child knows intuitively those who like him, and to them only will he be himself.

"The aim of the photographer should be first to make a portrait. And a portrait may be defined as a picture which portrays those fleeting and subtle qualities of expression, gesture, and pose so true to life—that you forget the picture and see, instead, the real child.

"The twinkle of the eye, the wistful shyness, wholly of babyland, the droll pucker of the mouth, the smile, the thoughtful brow, the sweet gravity—such as no other child shows in just the same way—one or all, call out instant recognition of the heart as well as the eye.

"Children's photographs are really a record of their lives. The years go fleeting away so fast that even a mother cannot carry in her memory the changes that take place in her boys or girls. What a joy to feel that one may look upon them in after years as they were in babyhood or boyhood."

"Ten thousand of these booklets have been sent out this summer to names similar to those on the first mailing list. It was designed partly to stimulate business in the quieter summer months, but chiefly to bring fall and winter work. Results have already become noticeable, though the mailing was finished only three weeks ago.

A Portrait Exhibition.

"Another valuable bit of advertising was our portrait exhibition, held last September. I sent to about fifty famous photographers in this country and Europe, asking for specimens of their work for exhibition. Some fine portraits were loaned by American and Canadian photographers, while in London, Paris, Rome, Berlin, and other Continental cities pictures were purchased outright. We made a specialty of portraits of famous persons, such as the King and Queen of England, the Kaiser, Emperor of Austria, Madame Bernhardt, Ellen Terry, President Loubet, Queen Wilhelmina and others. With this work were exhibited about as many portraits of

our own. There were five hundred altogether. Invitations were mailed and the exhibition lasted two weeks. Concerts were given in the gallery daily, and the show brought us a number of good notices from New York dailies. Perhaps nothing that we have done has been so effective in giving the Benedict Studios an artistic standing, demonstrating that good work could be done in a department store gallery, and at reasonable prices.

The Advertising Value of an Exhibition.

"The exhibition attracted the attention of a photographer in Scranton, Pa., and he asked for the loan of our pictures. Those by European men were sent, and he secured other portraits from American photographers. His exhibition, he told me, was perhaps even more successful than ours, because he does business in a smaller community. I can readily see how such a show would make a more permanent impression in a smaller city. But even in New York, with its endless distractions, the effect was by no means temporary. Visitors remembered it, and we trace work to the exhibition every day. This invitation will be useful to anyone who gets up something similar:—

An International Exhibit of Portrait Photography.

"You are cordially invited to attend the International Exhibition of Portrait Photography, which will be open at the Benedict Studios (7th floor Siegel-Cooper Building), Monday, September 26th, and continue for two weeks. At this novel and interesting exhibition will be shown the best examples of camera portraiture, by the leading photographers of Europe and America. Not only will an opportunity be afforded to view the work of celebrated photographers from nearly every part of the world, but the collection of portraits, in themselves, will be noteworthy. More than four hundred portraits of famous people will be exhibited, including members of the Royal families, as well as distinguished Americans.

"Music daily."

"On inside pages of this invitation were given lists of exhibitors and portraits of famous people." I believe that an exhibition confined to one's own work is as effective, and even better advertising, though the work of the best men in the photographic world has a drawing power that is very desirable. Then, when a photographer is not afraid to let his own work stand side by side with the best product of America and Europe, he assures his own artistic standing.

The Woman Operator.

"One mistake common to photographers is that of having barn-like operating and dressing rooms. The average operating-room is seldom carpeted, though carpeting in green or red is essential to give warmth and cheeriness and a homelike atmosphere that puts the sitter at ease. Another valuable form of indirect advertising is the woman operator for children and women sitters. Dozens of persons come to our studios and ask for Mrs. Bundy, our operator, who is not only a specialist in children's portraits, but has also been very successful in photographing men. Women have a certain confidence in the woman operator, especially where children are to be photographed, because children yield themselves to a sympathetic woman and better portraits result.

"Men might as well be left out of the photographer's advertising plans altogether. A man visits the gallery in charge of his wife, or because he was sent by her. If your advertising brings the mother and children the father will follow in course of time. I hope it is not necessary to add that by far the greater proportion of our booklets and invitations to exhibitions go to women.

Do Your Best for a Select Clientele.

"Newspaper advertising might be handled on the lines of our booklets—that is, educative talks about artistic portraiture. It would pay in smaller cities, I think. Here in New York I have

always thought that newspaper advertising would necessitate special prices, and have not gone into that medium. The booklets bring us all the work we can handle comfortably. One important point for the advertising photographer is to limit his business, so that his studio will never be crowded. The aim should be to attract the best class of patronage and always have leisure for each sitter."

JAS. H. COLLINS.

Photo-Mechanical Notes.

A New Red Sensitiser.

DR. KONIG, the introducer of Pinachrome and Orthochrome T, has recently invented two new dyes, one of which is particularly interesting to the photo-mechanical worker, as it specially sensitises for the red. Hitherto the best dye I have been able to obtain to sensitise for the red was ethyl violet. While this is difficult to use for dry plates, it is very satisfactory for collodion emulsion, and is now practically universally used for the red exposure in three-colour work with collodion emulsion. I therefore tested a sample of the new dye, "Pinacyanol," that Dr. Konig was good enough to give me, in collodion emulsion, and the result has proved it to be very much better even than ethyl violet used under the same conditions. The solid dye was made up in 1 in 1000 solution in 90 per cent. alcohol, and 4 c.c. of this solution added to 100 c.c. of Albert's emulsion, and with this a photograph of the spectrum of the arc light was taken, which is shown herewith:

From this it will be seen that the sensibility extends easily to wave length 6,800 A.U., whereas under the same conditions the ethyl violet-sensitised emulsion had nothing at all beyond 6,400, and up to there the density was not nearly so great, although exactly the same raw emulsion was used, the same developer, and time of development. In practical work this means that emulsion sensitised with "Pinacyanol" is much faster than ethyl violet emulsion under the normal red filter, and that it will record deep reds that would never be recorded by the ordinary red-sensitive plate, unless a much deeper red filter was used, and correspondingly long exposure given. The insensibility to green, which is shown by the black gap in the middle of the spectrum photograph, is an advantage, because it enables plates to be worked in great comfort with a green light in the dark-room, and in fact there was no fog when developing in copious green light, but there was instantaneous blackening on the slightest exposure to a very "safe" red light. If the dye be as suitable for dry plates as it is for emulsion, it will meet a need that has been felt for some time in three-colour work.

A. J. NEWTON.

Albumen in Fish-glue Resist.

APROPOS of the note on the enamel resist in last week's B.J., albumen is given in the majority of fish-glue formulae, without any reason whatever being stated as to why it is necessary or even desirable. However, a writer in the "Process Review" for February, 1904, stated that a solution containing albumen adhered better to zinc, than one without it. This has been tested by Mr. Gill, the teacher of the enamel class at the Bolt Court School, who, after repeated experiment, finds that a resist made from a fish-glue solution containing albumen

invariably gives way in the acid bath before the resist which does not contain the egg-white, all other conditions being exactly the same.

Masking for Air-brush Work.

In retouching prints with the air-brush, for the purposes of catalogue illustration, it is usual to cut paper masks to cover over the part of the work that does not require the colour sprayed on, otherwise it would be impossible to keep a sharp outline with this useful tool. Paper masks, however, in the case of intricate outlines are very difficult to cut and to adjust, and, as even the thinnest paper has a perceptible thickness, the colour tends to heap itself up against the paper, sometimes enough even to cast a slight shadow when the mask is removed. A better method is to take celluloid varnish and add to it a little coloured pigment (such as Venetian red), in order to make it easily visible, and then apply this paint over all the work which does not require air-brushing. When the varnish is dry, the colour may be sprayed on freely all over the print. This is then allowed to dry, and then a wad of cotton wool is taken, wetted with amyl acetate and rubbed over the print. This removes the celluloid varnish, carrying with it the unnecessary colour, while it does not touch work which was unvarnished. It will be seen that this affords a rapid and easy method of masking the most intricate work, work which it would occasionally be impossible to do in the usual way. The method serves on all kinds of surfaced photographic prints, but will not do on plain papers or Bristol boards (unless they are first sized), because the varnish soaks in. The odour of celluloid varnish or amyl acetate (which is like "pear-drop" sweets) is rather pungent, but it is probable that other materials could be adapted to the same method, perhaps, for example, plain collodion for the varnish, and mixed ether and alcohol to remove, only this would not serve for collodion printing-out papers.

Spitzertype.

In the current number of the "Photographische Korrespondenz," a somewhat indefinite note appears on a new process which has been discovered by Emanuel Spitzer, a well-known humorous painter of Munich. Any ordinary negative is used, without any crossed line, or irregular grain screen or asphalt dust. It is printed on to a metal plate and sensitised with bichromated gelatine, and then etched. The etching fluid is not stated, though it is said to be the same as in photogravure. The image is broken up in the etching bath by a kind of disintegration of the film. Several good examples are given, which were printed in the usual way with the text, and on examination with a glass the structure has a very similar appearance to a photogravure asphalt grain.

Etching Solution for Aluminium Plates.

F. W. Plews, writing in "Process Work," gives the following directions for preparations for (1) adding new work, and (2) giving aluminium a cleaning etch:—A good preparation for the plates when new work is to be added is the following: Acetic acid, 3 oz.; nitric acid, 1½ oz.; water, 100 oz. Apply with a brush and allow it to remain on the plate for about three minutes, then wash off and dry the plate, which is then in a condition for additions or touching up, etc., or a weak solution of oxalic acid may be used. For an etching solution to be applied before the work is rolled up, the following can be used: Gum solution 25 per cent., 8 parts; phosphoric acid 20 per cent., 1 part. Apply the phosphoric acid and gum to the plate and allow it to act for about 20 seconds, then wash off and gum up with a thin solution of pure gum, which must not be acid, but quite neutral, fan dry, and we may then proceed to roll up in the usual way.

The Adjustment of the Screen in Process Cameras.

A system of moving the line screen by a rack and toothed wheel and lever, is the subject of a recent patent (No. 24,036, 1904)

taken out by Edgar S. Hunter, Poppins Court, Fleet Street, London, and W. E. Hanchard, 57, British Street, Bow, London. The frame carrying the line screen moves on rigid bars situated within the camera itself. The rack is fixed at one end to the centre line of the frame carrying the line screen, and is rigidly guided in a frame placed outside the camera. The upper portion of the rack frame is provided with a slot and finely graduated scale, and the rack carries at its outer end an indicator which moves along the slot and over or by the scale when the rack is moved. For effecting fine adjustment a screw is arranged to come against the outer end of the rack shaft and slightly displace this latter when fine adjustment is being made, after which the screw is locked by means of a nut.

The construction of the camera will be understood from the accompanying figure:—

A is the frame or inner body carrying the line or other screen which is adapted to move on rigid guide bars B situated within the camera itself and provided with bearings. The frame A carrying the screen is moved by means of a rack C and toothed wheel D and lever E. The rack C is fixed at one end to the centre line of the frame carrying the screen and is rigidly guided in any suitable manner in a frame F located at the exterior of the camera. G is a slot provided at the upper part of the frame F, and H is a finely graduated scale located at the side of the slot G. I is an indicator carried by the outer end of the rack C and adapted to move along the slot G and over or by the scale H when the rack is moved. J is a finely threaded screw which engages with a corresponding screw provided in the frame F, and comes against the rack C, or a part upon which the rack is mounted, and displaces same for the purpose of finely and accurately adjusting the position of the screen with respect to the sensitive plate. L is a nut for locking the screw J in its adjusted position.

By the use of the above described actuating, adjusting, and indicating mechanisms the screen frame can be rapidly moved and fine adjustment rapidly effected whilst movement is imparted in a direct manner to the adjustable parts of the camera.

INTERNATIONAL EXHIBIT OF PHOTO-ENGRAVING.—From Jean Van Overstraeten, secretary, comes the announcement that in February, 1906, there will be held in Brussels an exhibition specially devoted to the photo-engraving processes, with special reference to their application to book illustration and bookbinding. By November 1, 1905, applications for space should be addressed to the President, Brussels Society for Typographical Studies, 51, Marché-au-Charbon, Brussels, Belgium.

Patent News.

Process patents—applications and specifications—are treated in 'Photo-Mechanical Notes.'

The following applications for patents were made between October 2 and 7:—

SELF-TONING PAPER.—No. 19,850.—Improvements in self-toning papers. Carl Soufus Poulsen, 65, Chancery Lane, London, W.C.

DEVELOPMENT.—No. 19,985. Improvements in developing and fixing photographic negatives and positives. William Fraser Claughton Kelly and John Arthur Bentham, 7, Southampton Buildings, Chancery Lane, London.

STORING NEGATIVES.—No. 19,933. Improved cabinet for storing photographic negatives, etc. Houghtons, Limited, and Alfred Sydney Pratt, 88, High Holborn, London.

EXPOSURE METER.—No. 19,962. An improved photographic exposure meter. Ilford, Limited, and Rowland Samuel Potter, 88, Quality Court, Chancery Lane, London.

APPLYING GELATINE EMULSION.—No. 20,148.—Improvements in applying coatings of gelatine, gelatine emulsion, varnish, or other substances, to strips or bands of celluloid, paper, or other material and in apparatus therefor. Henry Rheinlander, St. Leonards, Rodney Road, New Malden, Surrey.

A SEPARATING CASE.—No. 20,204.—A separating case for photographic papers during printing and development and the like. Charles Edward Dodsley, 47, Shrewsbury Road, Birkenhead.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

REFLEX CAMERA.—No. 22,698, 1904. The patent is for a movement of the mirror in a reflector camera, by which the mirror recedes from the lens as it moves into the horizontal position. The camera can thus be made shorter and a lens of shorter focal length employed. Within the body or case of the camera is a framework hinged at the base so as to be capable of rocking about a horizontal axis at right angles to the axis to the lens, and to the upper edge of this rocking frame or box is hinged one edge of the mirror so that it also can rock about an axis parallel to the axis upon which the box itself is capable of rocking. The box has sides, but is otherwise open from front to back, and the mirror, along with an auxiliary hinged lower flap, forms a closure for the front of the rocking box when the mirror is in its inclined position. The mirror is operated by engaging pins, which project centrally and laterally from its frame. These pins work in curved slots, the movements being governed by balanced springs, in such manner that when released the mirror automatically moves from its inclined to its horizontal position, and during this movement turns about its hinge on the rocking box. The rocking box allows of the forward and retrograde motion of the mirror, so that the latter in moving from its angular position during its upward movement, recedes away from the lens and again advances as it assumes its horizontal position. Abraham Kershaw, Dorrington Street, Leeds.

A WASHER FOR PLATES AND FILMS.—No. 2,083, 1905.—The apparatus consists of a frame A, formed with the arms *a* from which racks B are suspended and with a bearing *a*¹ adapted to engage a pivot *c* mounted on a base plate C. The racks B are furnished with

corrugated strips *b* for the reception of the plates or films; the strips being preferably perforated and so arranged as to permit the free passage of water between the plates. For washing the plates the apparatus is placed in a tank D furnished with an inlet *d* and an outlet *d*¹, the overflow of the latter being so placed as to maintain a constant level of water in the tank. The inlet *d* is arranged in the tank so that as the water enters it circulates

round the tank and imparts rotation to the frame with the effect that the plates are thoroughly washed. After the plates have been washed the apparatus is removed from the tank and the plates rapidly dried by mechanically rotating the frame A on its pivot; the frame being furnished with a pulley *a*² for this purpose. James Hazell and Albert James Chapman, 107, Mansfield Street, Kingsland Road, London, N.E.

PHONOGRAPH-CINEMATOGRAPH.—No. 413, 1905. The patent claims for the working of a phonograph and cinematograph in conjunction as well as methods of producing this effect. One is a signalling method:—A toothed wheel *c* (fig. 1) meshes with the

Fig. 1.

Fig. 2.

operating gear of a phonograph, which by means of a cog-wheel *d* and a contact *f*, *g*, effects the closing of a circuit at each revolution so that an electric bell *h* arranged in the circuit is made to sound at regular intervals. The operator of the cinematograph can turn the handle uniformly by observing the signals,

so that the phonograph and the cinematograph work together. Another method is, apply a brake to the cinematograph from the motor of the phonograph. In fig. 2 *i* denotes the operating shaft for the cinematograph, *k* a pulley, which is operated by a motor through the belt *l*, and *m* a brake disc, *n* is a brake lever rotatively fitted to *o*, the fore end of which lever carries an armature for the electro-magnet *q*. The winding of this magnet, similarly to the electric bell *h* of the previously described device, is situated (fig. 2) in the circuit controlled by the phonograph. By each closing of the circuit by the contact *f g* (fig. 1) the brake lever is moved by the electro-magnet towards the pulley *k* which rotates somewhat too fast. From time to time any "irregularities" are thus approximately corrected and both apparatus caused to turn approximately synchronously. Should there, however, arise too great a difference in the relative speeds the braking is augmented by hand. Oskar Meester, 18, Schiffbauher Avenue, Berlin, N.W.

New Materials.

The "Wellington" Christmas Greeting Postcards. Made by Messrs. Wellington and Ward, Elstree, Herts.

We have received from Messrs. Wellington and Ward samples of their P.O.P., bromide, and S.C.P. (gaslight) postcards. These, needless to say, exhibit all the good qualities possessed by the firm's other productions, and in addition are suitably inscribed to serve the purpose of Christmas cards. Dainty little designs, embodying expressions of goodwill, fill the place on the front of the card usually occupied by the message, and the backs are sensitised with either the well-known P.O.P., bromide, or S.C.P. emulsions. These cards are supplied in 6d. packets, containing six, with full instructions. Messrs. Wellington and Ward have also sent us a box of their lantern plates, and one trial of them has strengthened the good opinion we expressed when reviewing them earlier in the year. The pyro-ammonia formula given with these plates produces a particularly fine warm black tone, that appears suitable for nearly all subjects.

"Chic" Series of Christmas Card Mounts. Made by Kodak, Ltd., Clerkenwell Road, E.C.

This well-known series of Christmas card mounts do not belie their name of "Chic." "Chic" is the word that describes them exactly, and the aesthetic-minded photographer, be he professional or amateur, can desire nothing better wherewith to display the daintiest products of his camera. It is specially claimed for these cards, which are supplied in many varieties, sizes, colours, and styles, that they are British made. This should prove an extra inducement to the patriotic pictorial photographer to at least write Messrs. Kodak for their price list. To this, we can add, from personal inspection, that these charming Christmas card mounts show a most careful selection of suitable tints and designs, and offer ample scope for the choice of mounts to suit every kind of photograph, from "gaslight" to "gum." They range from plain to unobtrusive, yet still artistic, to elaborate colours and designs. Book-form mounts, as well as pretty calendars, with embossed wording, figure in the list at prices ranging from 9d. to 6s. per dozen. Particulars will be sent gladly on application.

Paget Self-toning Paper and Cards. Made by the Paget Prize Plate Company, Limited, Watford.

The Paget Self-toning Papers have long been well known as reliable productions, and their simplicity in working has rendered them among the most popular of modern printing processes. To the previous varieties cream crayon paper and card have been added, and these

should appeal very largely to the photographer who desires to secure an artistic method of producing his prints. The cream crayon surface adds considerably to the beauty of almost every print, and for large work no better vehicle, short of carbon, can be suggested. In fact, many of the specimens we have seen on Paget cream crayon paper would easily pass for first-class carbon prints. In use the paper requires the same treatment necessary for the older varieties. The print is carried a little further than required in the finished picture, and after washing for five minutes is simply fixed in hypo 3 oz., water one pint, for ten minutes. This gives warm brown tones. If colder tones are desired, the prints are placed in a solution of common salt (two ounces to the pint) for five minutes prior to fixing. A final washing is necessary, and that completes the process. To suggest toning a self-toning paper of the quality of the Paget is like painting the lily, but when we find recommended a platinum bath, giving fine olive black tones, and have visual evidence of the beauty of the results, we unhesitatingly recommend it. The toning bath suggested is: Potassium chloroplatinite, 15 grains; sodium chloride, 150 grains; citric acid, 150 grains; water to make 7½ ounces. For use, take one part of this solution and ten parts of water. The prints must first be put into a bath of common salt one ounce, water ten ounces, for five minutes, washed, and then placed in the platinum bath. In five or ten minutes, when all trace of red has disappeared from the prints when looked through, they are washed for five minutes and fixed in hypo three ounces, water one pint. Platinum toning tablets are supplied by the company, ready for use, by simply dissolving in water. The richness and fine qualities of this method of toning are sufficient to make every photographer give it a trial.

Fallowfield's Christmas Mounts. Made by Jonathan Fallowfield, 146, Charing Cross Road, London, W.

Each year as this season approaches we look forward to seeing the selection of dainty Christmas and New Year mounts which Mr. Jonathan Fallowfield has made a feature of his winter trade. The Christmas card, plus a photographic inset, appears never more popular than at the present time, and the selection now sent us by this firm amply proves that the best talent in design and printing has been requisitioned in their production. Slip-in cards, cards for pasting down, folders, motto cards, cards with embossed designs, and expressions of unctuous civility and affection crowd one another in the list, that will be sent free on application. The dealer or photographer will be very hard indeed to please who does not find something to his taste in its pages.

Lantern Slides. Made by Graystone Bird, 38, Milsom Street, Bath.

Mr. Bird's slides have long compelled our admiration for their pictorial quality, as well as for their technical excellence. In recent additions to his series which we have before us we find both these characteristics maintained at a high standard. The "life model" slide, a number of which are included in the selection, is not usually associated with pictorial aims, and probably it serves its professed purpose—the delectation of the Sunday school class—none the worse for that. But Mr. Bird's productions of this class go far to rid the life model slide of reproach, for they are excellent in themselves, apart from the story they illustrate. The supplemental catalogue for the current season will be sent on application.

The "Ensign" Developing Camsters. Made by Houghtons, Ltd., 88 and 89, High Holborn, W.C.

Developers made up to standard formulæ are always popular when put on the market in a way calculated to give the amateur photographer a minimum of trouble. Messrs. Houghtons' improved developing camsters are therefore likely to meet with a cordial reception by not only this class of photographer, but also by the worker who desires to know what he is putting into his developer. The contents of these

tins are constituted according to the formulæ published by the Imperial Dry Plate Company, and there are four kinds—pyro-metol, pyro soda, hydroquinone, and metol-hydroquinone. The chemicals are contained in the canisters in bulk, and only require dissolving in water for use. The trouble and bother of weighing out exact amounts are thus saved, yet at the same time there can be no doubt that the developer is rightly made up. In addition to this, the fact should be noted that the price of these tins is now 1s., as against 1s. 3d. when they were first introduced.

New Books.

"Nicola Perscheid's Photographie in Natürlichen Farben," by Herman Scheidemann. Leipzig: E. Haberland. M.5.

We were somewhat at a loss how to approach this work, because it has been practically repudiated by Perscheid in the German journals. After carefully reading it our attitude is definite.

What the author thinks is also obvious when he says: "In future no one will be satisfied, either in professional studios, or whenever colour is required, without gum printing. It is scarcely possible that within a reasonable time another process of colour photography can be discovered which shall give such successful results as the chromo-gun process worked out by Perscheid, inspired by Lumière's theory. This alone enables one to make an actual paper print in natural colours." Yet but a few pages before this passage he says: "When Perscheid wondered at Lumière's brilliantly-coloured diagrams (The italics are ours.—Eds. B.J.P.) at the Paris Exhibition of 1900, etc." Again, the author says: "Everything which has appeared in book form, in the journals, or in pamphlets, except Hübl's, is useless for the solution of the problem." The work of Du Hauron, Ives, Abney, Vidal, Lumière, etc., is useless! He tells us that Perscheid's process is absolutely original, and that such things as Lumière's transparencies cannot be considered as positive colour pictures. Forty-seven pages of this work are devoted to the theory of three-colour photography and polemic statements, such as we have quoted above. Fourteen pages are assigned to the necessary apparatus, and we learn that Perscheid's filters pass very narrow spectrum bands (which can hardly be said to be in accord with the latest ideas); that he has invented a special shutter (because the ordinary pneumatic shutter is useless), a clockwork arrangement which gives absolutely correct exposures, and a sliding back. The last, of course, has been in use in England for years. Then we come to the printing. Notwithstanding the forty-seven pages of trichromatic theory and polemics, we find it is not a three-colour but a four-colour, or, rather, a four-printing process, or more if you like. It is gum bichromate, and all the materials, which are kept secret, may be obtained from a particular firm. Naturally, the pictorial side of photography is not omitted, and the author ranges from D. O. Hill and H. P. Robinson to Hinton and Steichen. There is a three-colour half-tone frontispiece, after a nature study by Perscheid, that is poor; and, at the end of the book, there are some full-page illustrations from the trade catalogue of the firm supplying the necessary apparatus and materials.

"I Go a-Walking through the Country Lanes" is the title of Part I. of an exquisitely illustrated and printed series of books on nature subjects published by T. N. Foulis, 3, Frederick Street, Edinburgh. This part deals with our feathered friends, and is compiled from "British Birds and Their Haunts," by Rev. C. A. Jones, B.A., F.L.S. The pictures, which are triumphs of the type of work made popular by the Keartons, Oliver G. Pike, and others, are by Charles Reid, of Wishaw. Six parts are promised, and the cost is 6d. each.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Oct.	Name of Society.	Subject.
20	Blackburn Camera Club	"Gun Bichromate Process." Dr. Ivatt.
20	Colne Camera Club	"An Evening with the Phonograph." Mr. A. E. Wilkinson.
21	R.P.S. Exhibition New Gallery	Selections from the St. Louis Exhibition; Slides with Notes by Mr. T. B. Freshwater, F.R.M.S.
23	Dewsbury Photo. Society	"Taste and Selection." Mr. Percy Sheard.
23	Southampton Camera Club	"Lantern Slide Making." Demonstrated. Mr. V. E. Morris.
23	Halifax Camera Club	"Zigo and Carbon" (by permission) Demonstrated. T. Hillingworth & Co., Ltd.
23	Heaton & Dis. Camera Club	"How to Make Enlargements." Mr. Geo. C. Urwin.
23	Cripplegate Photo. Society	"The Camera Process of Photography." Mr. Alex. Mackie.
23	Luton Camera Club	Exhibition of Direct Prints.
23	Barrow Naturalists' Field Club	"Ecclesiastical Architecture." Illustrated. Mr. E. M. Young.
23	R.P.S. Exhibition New Gallery	"Here and there with a Camera for the Press." Mr. S. J. Beckett, F.R.P.S.
23	Oxford Camera Club	"In the Spanish Wilds." Col. Willoughby Verner.
24	St. Helens Camera Club	"Experiences of a Beginner." Mr. J. T. Elliott.
24	Hackney Photographic Society	Amateur Photographer Prize Slides.
24	Bristol Photographic Club	Annual General Meeting.
24	Nelson Photographic Society	Goetz Lecture—"What Can Be Done with a Hand Camera."
24	Darlington Camera Club	"Enlarging Apparatus and Exhibition of Enlargements." Demonstrated.
24	Birmingham Photo. Society	"Tabloid" Photographic Chemicals Demonstrated. Messrs. Burroughes, Wellcome, & Co.
24	Thornton Heath Photo. Society	Lantern Night.
24	Otley & Dis. Cam. & Art. Soc.	"Engelberg and the Bernese Oberland." Mr. G. Middleton.
24	Leeds Photographic Society	"Stratford-on-Avon." Mr. Harold Baker.
24	Gateshead Camera Club	Lecture by Messrs. Ilford, Ltd.
25	Leeds Camera Club	"Development." Demonstrated. Mr. John T. Garbutt.
25	Wallasey Amat. Photo. Soc.	Lantern Lecture with Wednesday Evening Society at Manor Road.
25	North Middlesex Photo. Soc.	Technical Meeting.
25	South Essex Camera Club	"Ozotype." Mr. T. Manley.
25	Edinburgh Photo. Society	"The Camera; and the Optics of Photography." Mr. H. Stewart Wallace, W.S.
25	G.E.R. Mechanics' Institution	"Selection of Subject and the Elements of Composition." Demonstrated. Mr. H. W. Bennett, F.R.P.S.
25	Boro' Poly. Photo. Society	"The Carbon Process." Demonstrated. Mr. Lafosse.
25	Coventry Photo. Club	"Iso Plates and Screens." Mr. E. H. Cooke.
25	Cricklewood Photo. Society	"Toning Bromides." Mr. F. Carter.
25	Croydon Camera Club	"Bromide Paper and Enlarging." Demonstrated. Mr. J. W. Eadie.
25	Tring Camera Club	"Bi-monthly Competition. Subjects: 1, 'Summer Landscape'; 2, 'Seascape'."
25	Huddersfield Nat. and Ph. So.	"Bromide Enlarging, Exposing, Developing, Fixing, Toning, and Mounting." Demonstrated. Mr. H. Crossley, Henderson Award.
26	London and Prov. Photo. Assn.	"Retouching." Demonstrated. Mr. John Way.
26	Harrogate Camera Club	"Focus." Slides, Stories Without Words.
26	Hull Photographic Society	"Toning Gelatino-chloride Prints with Platinum." Demonstrated. Mr. C. P. Proctor.
26	Handsforth Photo. Society	"Carbon Printing." Mr. D. Dunlop.
26	Glasgow Eastern A.P.A.	Last Night for receiving Prints for Federation Portfolio.
26	Balham Camera Club	"Some Slides and their Faults." Mr. J. H. Willie, R.P.S. Members.
26	Darwen Photo. Association	Lantern Night.
26	Liverpool Amateur Ph. Assn.	"Platinotype Printing." Mr. T. Longworth Cooper.
26	Leek and District Photo. Soc.	"Art in Photography, with Special Reference to Figure Studies." Rev. Henry W. Dick.
26		"Making of Lantern Slides. Messrs. Nibsdale, Prince, and Sutton."

WINTER programmes and fixture lists have been received from the Edmonton and District Photographic Society, the Otley and District Camera and Art Society, the Holmfirth Photographic Society, the Harrogate Camera Club, the Wallasey Amateur Photographic Society, and the Darwen Photographic Association.

At the Hove Camera Club, a useful innovation is announced for the winter season. This takes the form of four practical lecture-demonstrations by Mr. J. H. Gear, at the Club Rooms, 55, Western Parade, Hove. Mr. Gear's ability as a lecturer is too well known to need comment, and the Hove Society is to be congratulated on this step in the right direction.

DERBY PHOTOGRAPHIC SOCIETY.—Sir William Abney, K.C.B., F.R.S., and Ald. G. Herbert Strutt, J.P., have been re-elected patrons of this society for the ensuing year, together with Dr. E. Collier Green as president, and Mr. S. T. Lee and Mr. W. R. Bland as vice-presidents.

CROYDON CAMERA CLUB.—In a demonstration on "Transparencies for Enlarged Negatives," by Mr. F. W. Hicks, on October 10, the case of carbon versus dry plates was fully considered. With the former, Mr. Hicks said, a much truer scale throughout no doubt was obtained, and if the negative to be printed from was of a really plucky variety, its employment was almost compulsory. On the other hand, the manipulation of dry plates was familiar to all, and, by adjustment of exposure and development, one could very widely vary results. Printing in skies with the latter was also a comparatively simple operation compared to carbon, and if an error was made, it could quickly and easily be rectified by exposing another plate. He preferred metol as a developer, as having a minimum tendency to block the shadows, and an "ordinary" plate to process or lantern, which generally gave too brilliant positives. In the discussion which followed, Mr. H. P. C. Harpur raised a point concerning the enlarged negative which, he said, might very easily be overlooked. If a trial exposure on a small plate was made, and a standard time for development fixed therefrom, then the same proportionate amount of developer, should be employed for the small test negative as for the large ultimate one. Assuming a proportionate smaller quantity of solution was used for the latter, then a relative greater amount of bromine would be liberated by development per unit volume of solution, and would consequently alter the gradation of the enlarged negative. In actual practice he had found this was so by comparing the two negatives. Mr. E. A. Salt, whilst acknowledging Mr. Harpur had undoubtedly "an eye for the beautiful," denied its capacity for comparing minute differences in plate densities. No doubt a difference would exist in the case stated, but in connection with this, a large plate always appeared to have a different printing value from a small one. The President (Mr. W. H. Smith) confirmed the latter remark, and added that, as a matter of fact, the most experienced printer could never gauge accurately how any particular negative would turn out. What might seem a perfect negative would, on trial, frequently yield an unsatisfactory print, and to some extent vice versa.

ULSTER AMATEUR PHOTOGRAPHIC SOCIETY.—The opening meeting of the twenty-first session of this society was held in the club rooms, the Museum, College Square North, on Monday, October 9. Mr. David Elliott, B.A., T.C.D., presided, and a lecture by Ellis Kelsey on "Night Photography" was delivered.

BRIERLEY HILL CAMERA CLUB.—The annual meeting of this club was held on Wednesday of last week at the Technical Institute. Mr. O. Gibbons was re-elected president, Mr. J. Thomas secretary, and Mr. W. C. Jones treasurer.

The Hull Photographic Society opened its winter session on October 5 with a social evening.

CROOK CAMERA CLUB.—W. Sadler, representing Messrs. J. J. Griffin and Sons, Ltd., gave a demonstration on Velox paper printing, developing, and toning, etc, before the members of this club on October 11.

HARROGATE CAMERA CLUB.—The opening lecture of the session was delivered by Mr. Godfrey Bingley, President of the Yorkshire Photo-

graphic Union, on Friday, October 6. His subject was "Warwickshire, Gloucestershire, and the Wye Valley—Illustrated." On Thursday, October 12, a demonstration on "Enlarged Negatives" was given by F. Rust, of Leeds.

SOUTHAMPTON CAMERA CLUB.—On October 9, Mr. Harvey Piper (Hon. M.S.A.) appeared before this society to deliver the first of his two lectures upon Westminster Abbey.

WANDSWORTH CAMERA CLUB.—At a meeting held on Monday, 16th inst., at the Club-room, 106, High Street, Wandsworth, a lecture by G. T. Harris, F.R.P.S., on landscape photography, illustrated with lantern slides, was read by the hon. sec. It was remarked how little care is bestowed on the important process of fixing. The majority of workers shot an unknown quantity of hypo into an unknown quantity of water, and then worked the bath until saturated with silver. The writer recommended a bath made up of: hypo, 4 oz.; sodium bisulphite, $\frac{1}{2}$ oz.; water, 20 oz.; and a second bath half the above strength. After the plate has been immersed in the first bath until the unconverted bromide in the film has been removed, it is placed in the second bath for ten minutes.

CATALOGUES AND TRADE NOTICES.

"ENLARGING ON Kodak Bromide Papers" is the title of a new Kodak Handbook. It is really an entirely new edition of No. 1 of the series, and is full of interesting and instructive information on bromide paper work and enlarging. The price is 1d. only, and it can be obtained from most dealers, or direct from 57-61, Clerkenwell Road, E.C.

MESSRS. W. BUTCHER AND SONS, Camera House, St. Bride Street, E.C., have now ready a series of catalogues for winter goods, chiefly of lanterns and lantern sundries. A large lantern list is a convenient reference volume for dealers, to whom only it will be sent.

"THE Telephoto Lens" is the subject of a most handsome booklet produced by the firm of C. P. Goerz, 4 and 5, Holborn Circus, London, E.C. It is an elementary treatise on telephotography in reference to the use of the Goerz negative attachment, and is most convincingly illustrated with a large number of reproductions, showing what can be accomplished. The series of photographs is as powerful an argument as can be had in favour of the telephoto principle, and includes examples of landscape, architectural and natural history photography on the telephoto principle. The very handsome book will be sent free.

It may not be generally known that the late Colonel Frank Rhodes was an enthusiastic amateur photographer. Whether he took a hand camera with him when acting as war correspondent our Cape Town informant cannot say, but at the Groote Schuur homestead he manipulated a whole plate outfit. When the Cape-town Photographic Club visited the famous grounds, Miss Rhodes, the sister, told the members to go where they liked, in the house and out of it until refreshments were ready. When Colonel Frank Rhodes received a large body of the Mountain Club, he also photographed them, sending several dozen copies to the secretary for distribution amongst those portrayed.

MESSRS. J. J. GRIFFIN AND SONS, LTD., have arranged to hold a Velox Exhibition at the Chamber of Commerce Rooms, 44, Mosley Street, Manchester, on October 26, 27, and 28. A lecture will be given each evening by Mr. Harry Wade, of Manchester, entitled "Velox and Some New Applications." In addition to this, practical demonstrations on the working of Velox paper will be given. Bona-fide amateur photographers can, however, obtain admission to the exhibition on presentation of visiting card.

News and Notes.

PHOTOGRAPHS for the Press.—The London Studio, of 20-22, St. Bride Street, Ludgate Circus, London, E.C., announces that it has opened a special department for the sale of photographs for the illustrated press. The advantages to a photographer of thus dealing through such an agent are that his picture can be offered to a number of papers, that the most likely papers can be approached, and that the engraver-agent is already in touch with the newspapers through his own business of supplying blocks. It may also happen that a photograph, which would otherwise be declined, will be accepted if the block can be guaranteed in time; such "rushed" work being a special feature of the London Studio business. Further, the London Studio hopes shortly to be able to arrange with a number of papers to let photographers on its lists "cover" all suitable events for the papers. It invites correspondence from photographers as to the districts which they can thus undertake.

MR. RUDOLF EICKEMEYER, JUN., who has for some years been manager of the "Campbell Studio," at 564, Fifth Avenue, New York, and who has won a world-wide reputation for artistic and beautiful work, has purchased a half interest in the studio of Davis and Sandford, and on December 1 the name will be changed to Davis and Eickemeyer. Mr. Sandford's interest in the business ceased nearly four years ago, Mr. Davis becoming sole owner. Mr. Davis and Mr. Eickemeyer, we understand, will both give their personal attention to all patrons.

MONEY in Postcards.—We have often commented on the business openings which the picture postcard craze has created for the photographer, and we have been glad to hear of many cases in which the cultivation of this branch of trade has brought good results. One great factor in postcard publishing being promptitude of issue, we are interested in quoting from a letter from the London Studio, of St. Bride Street, Ludgate Circus, with whom rapid production of postcards has been made a specialty. "Floods occurring at Bray, near Dublin, we received, at 11 o'clock one morning from Mr. Killick, the very well-known photographer there, two capital photographs, with an order for 1,000 postcards from each, and a request to hurry up. We made the blocks, printed and interleaved the postcards, cut up and despatched by 3 o'clock the same day. We enclose you a copy of one of the cards [The specimen is a very good half-tone.—EDS. B.J.P.] to show you what the quality was like, and when we mention that we also got half-a-guinea each for Mr. Killick for use of the photographs in the 'Daily Mirror' and 'Daily Graphic,' you will see that we can claim some little credit for looking after our customers' interests."

PLATINOTYPE as it is Worked.—Overheard at the Platinotype stall at the R.P.S. Exhibition:—Visitor to Demonstrator: "I like your process, but the paper rots so." Demonstrator: "Rots! I don't understand." V.: "Yes, rots all to pieces, although I work exactly according to your instructions." D.: "What method of development do you use?" V.: "The hot bath." D.: "And then?" V.: "Then I place it in the three hot acid baths." D.: "Hot acid baths? But our instructions don't say you should heat the acid baths." V.: "Well, they don't say you *shouldn't*. And I read in all the text books that all solutions should be of approximately the same temperature when developing in order to avoid blisters." Demonstrator collapses for a moment, and then goes on politely to explain why blisters need not be feared with platinotype.

A SELECTION of current postcards in black and colours reaches us from the British Photo-Engraving Company, Coventry, one of the earliest firms to go into the business of supplying photographers with

postcards. The company is able to show some extremely attractive work, and we are glad to hear from them that photographers have done good business, not only in postcards of local views and events, but in those from negatives or photographs of their own customers.

A PHOTOGRAPHIC exhibition is announced for May 15 to 17 in connection with the Clevedon Art Classes. The hon. secretary is the Rev. E. A. Sandford, 18, Hallam Road, Clevedon.

A PHOTOGRAPHIC Society for North London.—As a result of the recent successful exhibition at Highbury, a preliminary meeting will be held on Thursday next, the 26th inst., at 8 p.m., at Highbury Vale Mission Hall, Myrtle Street, Blackstock Road, N., to discuss the formation of a photographic society for the Highbury and Finsbury Park districts. All North London photographers are invited to attend.

THE death is announced of Mr. Richard Hedges. The deceased had retired from business as proprietor of the London and Coventry Photographic Company, Jesson Street, some time ago, and his death took place at Croydon, where he had gone to reside.

THE Edinburgh Photographic Society's annual exhibition will be held at the Society's Hall, 38, Castle Street, Edinburgh, from Saturday, February 24, to Saturday, March 10, 1906. The judges are J. Craig Annan, W. S. MacGeorge, A.R.S.A., and Arch. Cochran. Handsome plaques are offered in the open class, and full particulars will be supplied by the Hon. Secretary, J. S. McCulloch, 3a, North Street, David Street, Edinburgh. Entry forms are now ready.

THE Leeds Camera Club Syllabus and Exposure Note Book is a bulky publication, and does credit to the secretary, Mr. F. G. Issott, who so ably managed the last Northern Exhibition at Leeds. Members passes, notes on exposure and other useful information is included in addition to spaces for exposure notes and formulae.

A PHOTOGRAPHIC union for Lancashire and Cheshire was formed on October 9. Delegates from the Lancashire and Cheshire Societies attended the first meeting at the rooms of the Liverpool Amateur Photographic Society, 9, Eberle Street, Liverpool. Dr. Thurston Holland, of the Liverpool A.P.S., and Mr. W. Tansley, 22, Chapel Place, Liverpool, of the Everton Camera Club, were appointed chairman and secretary respectively (pro tem). A meeting will be held for election of officers, etc., as soon as a return is to hand of delegates appointed by the societies joining.

POPULAR ASTRONOMY.—At the Great Queen Street Theatre an entertainment of a novel character has been given during the week. Aided by a series of astronomical photographs, a large number of them being well-known Lick and Weinek photographs, Professor Gerhart Heltman discusses in a popular manner many of the most interesting astronomical problems. In presenting a series of photographs of the Martian Canals, he discussed the views of Mr. Percival Lowell on the question of the character of the canals, and the inferences which he draws respecting a hypothetical population of Mars.

CLOSING DAYS OF R.P.S. EXHIBITION AND SALON.—Our readers are reminded that the exhibition of the R.P.S. at the New Gallery, Regent Street, closes on Saturday, October 28. Miss Acland will repeat her lecture entitled "A Visit to Gibraltar" in the evening. The Photographic Salon at 5a, Pall Mall East, S.W., will close on Saturday, October 21, at 6 p.m.

THE TELL-TALE FLASHLIGHT.—We read in a morning paper that on the occasion of a recent "first night" at a West-End theatre a flashlight photograph of the audience was taken between the acts. Permission was first asked of the audience by the leading actor, and then the camera was produced and the flashlight made. We read, however, that the most curious part of the proceedings

was supplied by the audience as soon as the announcement was made. Ladies promptly produced small mirrors and arranged their hair and flowers in their dresses, etc., but the commotion caused by members of the audience who did not want their photographs taken at all gives most occasion for thought. Our contemporary suggests these individuals were probably guilty young men and certain husbands, who had gone to the theatre under conditions they did not desire to be known to all the world. The invitation "not to move" by the photographer was passed unheeded. Fans were put up in front of certain feminine faces, and some of the men made grimaces analogous to those made by the clients of M. Bertillon when he levels the anthropometric engines on them.

LECTURES AT THE R.P.S. EXHIBITION.—The following lectures will be given at the New Gallery, Regent Street, during the ensuing week: Saturday, October 21, Selections from the St. Louis Exhibition; slides with notes by T. E. Freshwater, F.R.M.S. Monday, October 23, Here and there with a Camera for the Press, by S. J. Beckett, F.R.P.S. Thursday, October 26, Daily Life in Japan, by Satori Kato, illustrated with slides made and coloured by Japanese artists. Saturday, October 28, "A Visit to Gibraltar," by Miss Adland, F.R.P.S.

The Annual Traill Taylor Memorial Lecture will be given on October 24, at the meeting of the Royal Photographic Society, in the New Gallery, 121, Regent Street, W., at 8 p.m., by Mr. Chapman Jones, F.I.C., F.C.S. Subject: "Photography the Servant of Science." Admission by tickets, available on application to the Secretary of the Royal Photographic Society, 66, Russell Square, London, W.C.

The members of the Photographic Club have arranged to hold their "Second Sumptuous Social Supper" in their club room (Red Cross Hotel, Paternoster Square), on Wednesday evening, November 15, for members and friends.

The entry form and prospectus of the third annual Scottish National Salon have been sent us. This year the Salon promoted by the Scottish Photographic Federation will be held at the Victoria Art Galleries, Dundee, opening on Saturday, January 13, 1906, and closing Saturday, February 3. There are no awards and no entry fees, and the pictures submitted will pass a board of selection. Entries close December 30, and all communications should be addressed to the hon. sec., V. C. Baird, Broughty Ferry.

PARTICULARS of the Hove Camera Club's tenth annual exhibition have been sent us, and, as previously announced, this forms one of the trio of societies that have for the past few years identified themselves with photographic activities in the south of England. In addition to a special plaque awarded by each of the three societies (Southampton, Hove, and Southsea), a special joint award is offered every year to the exhibitor at all three exhibitions whose collective exhibits shall be judged to be of the highest merit. This year it takes the form of a handsome bronze salver measuring 11½ inches in diameter. It is a copy (by Messrs. Elkington and Co.) of a silver salver in Rosenberg (Castle, Copenhagen). The Hove plaque is also worthy of mention. It is a miniature in bronze of "L'Angelus," by G. Dupré, and fourteen copies are offered in the open classes. The judges will be Messrs. C. Job, J. C. S. Mummery, and J. H. Sussex Hall, and the last day for entries is November 21. Entry forms and full particulars can now be obtained from the hon. secretary, A. R. Sargeant, 55, The Drive, Hove.

A PHOTOGRAPHIC section of the Plymouth Exhibition is announced. Special awards are offered, and there are no less than fourteen open classes with medals for each. The judges are H. Snowden Ward and H. S. Hill. Entry forms are obtainable from the secretary, A. D. Breeze, Great Western Chambers, 41, Union Street, Plymouth.

Commercial & Legal Intelligence

R. PERRY AND SON, LIMITED.—This company has been registered with a capital of £1,000 in £1 shares. Object, to acquire the business of a chemist and druggist lately carried on by H. N. Perry, at 73, High Street, Gravesend, as R. Perry and Son, to adopt an agreement between Miss Mary W. Perry and Miss Agatha A. C. Perry, and to carry on the above business and that of dealers in photographic apparatus and accessories, etc. No initial public issue. The first directors (to number not less than three nor more than four) are Miss Mary W. Perry, Miss Agatha A. C. Perry, G. E. Clay (chairman), and G. Curry. Qualification, £10. Remuneration, £2 per annum, divisible. Registered office, 73, High Street, Gravesend.

UP-TO-DATE ARTS AND INVENTIONS, LIMITED (86,104).—Registered Oct. 10. Capital £3,000 in £1 shares. Object, to carry on the business of photographers, photo and general engravers and printers, dealers in photographic apparatus and materials. D. C. Dallas is permanent managing director, with £182 per annum, and A. B. Snell is assistant-manager and assistant-superintendent of the art department. Registered office: 8, Theobald's Road, W.C.

ALLEGED BOGUS CANVASSEER.—Ernest Hopper, 28, described as a traveller, living at 79, Limerston Street, Chelsea, was charged on a warrant at the West London Police Court, before Mr. Lane, K.C., on Monday, with obtaining 7s. 6d. by false pretences from Miss Jean Williams, a young lady living at 40, Kensington Park Gardens. Miss Williams stated that on September 29, the prisoner, who gave his name as Davies, called at the house and showed her and her sister some photographs. He wanted to know if they would give him an order. Witness said she did not want to be photographed, but she handed him a group, and told him to make an enlargement of one of the figures in the group. He said he was canvasser for a Mr. Mallia, a photographer, of Oxford Street, and he promised to get the enlargement done. She paid him 7s. 6d. and he gave her a receipt for 8s. telling her he was allowing her 6d. as discount. He went away and she never saw him again, nor did she receive the enlarged photograph or the group she had lent him. John Mallia, photographer, of 285, Oxford Street, said he did not know the prisoner. He believed he saw him once in July, when he came to try and get a camera by pretending that he came from a friend of his (Mallia's). Witness had never given him any orders nor received any orders for execution. A man named Davies used to be in his employment, but he never saw the prisoner. Prisoner: I was engaged by Davies to get orders, and I sent him a number. "I always signed for the payments in the name of Davies. I have not seen Davies for some time, and I suppose he has been carrying on systematic frauds and dragged me into them. Mr. Mallia said he had received many complaints about these frauds, and, after Miss Williams' letter to him, he communicated with the police. Det.-Sergt. Burnie stated that he arrested the prisoner in New King's Road. When the warrant was read to him he said, "Yes, I left the group on an omnibus and lost it." In answer to the magistrate the officer said he believed there was a real Davies, and the warrant was made out against Davies; as the prisoner called himself Davies witness arrested him. A remand was granted.

RE JOHN WILLIAM CALVERT, photographer, 58, Stonefall Avenue, Starbeck, and Chapel Street, Harrogate.—The first meeting of the creditors interested under this failure was held at the offices of the Official Receiver for the York district. The summary of accounts showed liabilities expected to rank for dividend amounting

to £104 16s. 10d., and assets estimated to produce £13 14s. 7d., thus showing a deficiency of £91 12s. 3d. The causes of failure were stated to be heavy rents and rates, falling off in trade, and bad debts.

At the Wigan County Court on Tuesday in last week, before his Honour Judge Bradbury, Alphonsus J. Smith, trading as A. J. Smith and Co., photographer, Moot Hall Chambers, Wigan, claimed £5 from Mr. Jas. Marsden, J.P., as damages for illegal removal of two show cases. Plaintiff conducted his own case, Mr. A. Ellis (Messrs. Peace and Ellis) appearing for the defendant. Plaintiff said that he took the business over from Messrs. A. G. Taylor and Co. Mr. Marsden's agent, Mr. Cook, had agreed with Mr. Taylor that two show cases should be exhibited at the entrance to the chambers, as was usual with a photographer's business. That was in 1903. He took the business over on March 9 this year, and wrote a letter to Mr. Crook, and also saw Mr. Marsden. Mr. Ellis remarked that the plaintiff was not their tenant. They had a lease with Mr. Taylor. There was no clause in the lease allowing him to put show cases out, but Mr. Marsden gave him verbal permission to put two show cases on the bottom floor. On August 10 that permission was withdrawn for certain reasons, and he produced the letter withdrawing it. They then took down the show cases and placed them in plaintiff's studio. They were put up again and taken down again, and, altogether, that happened three times. When they found that plaintiff would not take them back they took the show cases to defendant's warehouse, and wrote to him informing him that he could have them if he applied for them. If the plaintiff claimed to be tenant he must be a trespasser. He had no right at all. Plaintiff said he notified them that he was going there, and Mr. Crook came up on several occasions during the three months and said nothing at all to him. He naturally concluded, knowing his references were satisfactory, that he was the tenant. Mr. Ellis: Have you paid rent to Mr. Marsden?—To Mr. Taylor, by arrangement. Mr. Ellis: Did Mr. Crook tell you to pay the rent to Mr. Taylor?—They told me to get Mr. Taylor's solicitor to transfer the lease to me. On August 10 did Mr. Crook come to you and show you a letter he was sending to Mr. Taylor?—He showed me a letter addressed to Mr. Geo. Taylor, but as I was not Mr. George Taylor I told him to send it on to him, and anything he had to say to me, to say it. Mr. Ellis read the letter: "I hereby give you notice that I withdraw the verbal consent given to the exhibition of two show cases at the entrance to Moot Hall Buildings, and request you not to hang them at the entrance any more after this date." His Honour: Plaintiff has no case, because you admit you were told after the first removal that the show cases would not be allowed to be there. You were told they would not be allowed to be there, but after that you chose to put them up again. They removed them, and they have them in their possession. If you wanted to obtain them you could have had them. You have no right, and Mr. Taylor cannot give you any right to put them there except you got permission from defendant. Therefore there is judgment for defendant, with the usual costs.

ANOTHER case in which Messrs. A. J. Smith and Co. were the defendants also came before the Wigan Court. Action was brought by Messrs. Prescott and Bold, architects, occupying premises in Moot Hall Buildings, below those of Messrs. Smith, for compensation in respect of damage done to drawings through the negligence of the defendants. The plaintiffs' case was that a tap in the defendant's room had been left running one night, and that the water had done the damage. For the defence it was stated that the sink had been choked up through a caretaker throwing dirty water down it. Verdict for the plaintiffs for £16 10s. and costs.

Correspondence.

FRATERNITY IN PRACTICE.

To the Editors.

Gentlemen,—Perhaps the view of an onlooker may be of some interest when it is on a matter which forces itself upon his notice. Of course my experience with the British professional is limited, but my visit to England this summer re-impressed me with the feeling that there are comparatively few close intimacies—at any rate they are not so apparent as many we have in the States. For example, Strauss of St. Louis, Stein of Milwaukee, Rinehart of Omaha, Benjamin of Cincinnati, Steffens of Chicago, and Clark of Detroit, make a business of meeting every two months at the studio of one or the other of the set for a couple of days' communion. They ransack the place from cellar to attic, they discover whatever is unusual and good in the man's methods and procedure, and when they get home they apply it to their establishments, and if the man has a faulty method, they correct it then and there and get the new scheme into working order before they leave—whether it be in the skylight or dark-room, or printing shop.

The business department is gone over minutely, and in the same way is commented upon and criticised; the ways of interesting new customers, of re-interesting old ones, advertising, handling of accounts, etc., etc., are each taken up with a generosity and wholesomely frank feeling that makes for the good of the visitors and the man visited. When you consider that the distance from Omaha to Detroit is greater than from Land's End to the uttermost part of Caithness, you can understand that they must consider these intimacies of real value.

"But," you say, "we in Britain are so much closer geographically that to invite intimacies of this kind would be dangerous; we are none of us so far apart but that we are competitors." I would add that not a month passes but that some committee of the Metropolitan Section of the Professional Photographers' Society of New York holds a meeting for one purpose or another in some of the New York studios, and the good that each man gets is balanced by the good he gives. Pictures are brought out and shown—not hidden—and often result in a couple of hours hearty discussion. Truly, I think this feeling is one of the strengths of the professional in the "States."

PRIE MACDONALD.

141, Broadway, New York,
October 3, 1905.

LEAKY ROOFS.

To the Editors.

Gentlemen.—The following experience may be of some use to our fellow professionals re leaking roofs. I was greatly bothered with the same, though my studio is a new one. We tried everything—white lead by the cwt.—but with no avail. After much thought, I hit upon a plan which has acted like a charm. I got a cabinet-maker to run down each side of the sash beams in the roof cabinet-makers' moulding, first coating the beams and the moulding thickly with white lead. The moulding acts as a gutter under all the top glass, and carries all the water and moisture from the glass out under the eaves. I got the whole job done for some 20s., and am not now at all bothered with leaking roofs.

I trust this explanation is intelligible, but should anyone like to

see my studio roof, or wish for further particulars, I shall be happy to do all I can to help them in this most serious difficulty.—Yours faithfully,

JAMES CLARK.

October 13, 1905.

A REPLY TO CRITICISM.

To the Editors.

Gentlemen,—With reference to your notice re the Land of Nod, it is easy enough to act the critic without knowing particulars. May I point out, in self justification, that we unfortunate professional photographers have frequently to give in to the ideas of children's parents? The picture I do not in the least defend, but I may add it is an order for ten 24 by 18 carbons at £5 each, on the understanding it is exhibited.—Yours truly,

JAMES CLARK.

October 13, 1905.

WARMING THE STUDIO.

To the Editors.

Gentlemen,—Anent your remarks in to-day's B.J.P. re heating of studio by pipe stoves and the objection caused by the dust from the fine ash produced by these, may I mention a system I have adopted which obviates this difficulty, and has some other merits? Under my studio is an apartment of similar size used for toning, washing, mounting, etc., in which I have a close stove, enclosed on three sides by 4½ in. brickwork to the ceiling. On the other side is a hinged sheet-iron flap, and in the floor above is an iron grating. During that part of the day in which the studio is in use the grating is kept uncovered, the heat from the stove ascending and warming the studio. At dusk the grating is covered with a rug, and the sheet-iron flap in work-room opened, whereby the heat is directed to this lower apartment. All the stoking and clearing out is done independently of the studio, and a large cast-iron boiler on the top of the stove, with a tap, provides a supply of many gallons of boiling water in the course of the day. Having had this system in use in three different studios since 1878, I have never regretted adopting it.—Yours faithfully,

WM. SALMON.

The Studio, 103, High Street, Bedford,
October 13, 1905.

THE REMOVAL OF BLACK MARKINGS FROM BROMIDE PRINTS.

To the Editors.

Gentlemen,—Having like many other people suffered much from the black markings so commonly found on glossy bromide prints, I venture to send you a remedy which I have found much quicker and more efficacious in removing them than the methylated spirit often recommended. It is, briefly, soap and warm water. I find that if a piece of cotton wool be well soaked with warm (not hot) water, then thoroughly soaped and rubbed on the prints, that it not only quickly removes the markings, but also improves the appearance of the print materially. It is well to treat the prints with alum before rubbing, and after so doing I find there is no risk of abrasion to the surface if reasonable care be exercised. If it is required to squeeze the prints, care must be taken to thoroughly wash them after the treatment with soap. I do not know of anyone who has tried this method; but it is quite possible that many of your readers know of it, and I only venture to send these few particulars thinking that possibly it might be of use to some.—Yours faithfully,

MURIEL DARTON.

6, Ribblesdale Road, Hornsey, N., October 16, 1905.

Answers to Correspondents.

- *.* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- *.* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *.* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- *.* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

F. Maudsley, 73, Queen's Park Road, Blackburn, Lancashire. Photograph of Master T. Morris and Photograph of D. Morris, both in Swimming Costume.
A. Lamb, Gowthorpe, Selby, Yorkshire. Photograph of J. O. Andrews, M. Scott, and Luke White, M.P. Photograph of G. L. Fox and Lieut.-Colonel T. Hardon.
W. Dainly, 119, Turtton Road, Bromley Cross, near Bolton, Lancashire. Photograph of the Blair's Hospital Convalescent Home, Bromley Cross.
J. H. Moody, High Street, Aberavon, Port Talbot, Glamorgan. Photograph (Combination) of a Placed Group of the Aberavon and Port Talbot Football Team, 1905-6, in a Frame.
W. Jubb, The Lodge, Harden Moss, Holmfirth. Photograph, Harden Clough, Meltham.

J. C.—We have no such intention.

INFRINGEMENT OF COPYRIGHT.—A firm of publishers has made use of the enclosed copyright photographs for reproduction. Kindly inform me as to the amount of damages I could claim, and how I should proceed in the matter. Also state if it be necessary to mark print copyright?—J. W.

It is not necessary that the print be marked "copyright." If you are a member of the Professional Photographers' Association, we should recommend you to put the matter in their hands to act for you. Failing that, you should entrust the matter to a solicitor, with instructions to take action for penalties and damages. It is possible, however, if you write to the firm of publishers telling them that they have infringed your copyright, they will come to reasonable terms with you, and thus avoid law proceedings. We cannot say what damages you should claim, as we can have no idea what damage you have sustained by the piracy. You can judge that better than anyone else.

E. B. AND SON.—The copyright in both negatives belongs to those who paid you for taking the picture, and not to you, and you had no right to use it for purposes of your own. We do not reply to correspondents by post (see notice to that effect at the heading of this column). At your request we have not published your letter.

COLOURS FOR MINIATURES.—Could you give me the address of firms who supply dyes for colouring miniatures for trade purposes, as per enclosed sample?—H. COMER.

The colours are supplied by all the large dealers, such as Fallowfield, Marion, Houghton, and others; Mawson and Swan also supply dyes for the work.

THE EYES IN PORTRAITURE.—In the "B.J." report of Mr. C. H. Hewitt's lecture to the London and Provincial P.A. on portraiture, it is stated that for correcting defects the "larger eye should be placed nearer the camera." I should be greatly obliged if Mr. Hewitt, or someone, would kindly say why—because I should have thought the reverse would have been better, for the nearer to the camera the larger an object appears. Would it not tend to equalise the eyes if the small eye was near to the camera and enlarged, and the large eye farther from and reduced?—G. H.

Mr. Hewitt writes:—"With the average size of head and

focus of lens the difference between the distance of the nearer and further eye is so slight that the actual diminishing effect of distance does not come into play. But, unconsciously, the mind associates diminution of size with greater distance, and so feels that the eye is smaller because it is further away. It is also possible that as the more distant eye will frequently be the one in shadow, its lesser size will, on that account, be less apparent.

SPOTS.—We cannot satisfactorily account for the spots, but should strongly advise you to increase the strength of the hypo bath to 3 oz. to 1 pint, and add to every pint $\frac{1}{4}$ oz. of sodium sulphite and $\frac{1}{4}$ oz. of salt. Immerse your prints before toning in a 10 per cent. solution of common salt, then wash for ten minutes, and tone with gold. Then wash for ten minutes, tone with platinum, immerse in a fresh salt bath, wash thirty minutes, and then fix. We do not think that the prints would be more permanent toned with platinum alone, and, provided your starch paste is freshly made, we should advise no change.

STRIPPING.—1. I shall be glad if you can help me. I have tried to employ the method given on July 28 last, "B.J.," p. 589, for "Saving Broken Negatives." Of course, I get all right up to putting the paper on, but I find that the film shows no tendency to stick to the paper or leave the glass, although I have well rubbed it down and kept it under pressure for some time. Of course, when dry, the paper and film and glass are closely stuck together. Nor can I raise a corner of the film as directed; my film appears quite rotten, and, if touched, comes off in small pieces. I have two broken plates which I am anxious to transfer, and any advice will be acceptable. Can the fact that my negatives are fixed in an acid bath with some chrome alum have any bearing on the matter? 2. Also, "B.J.," October 13, p. 804. Can you say what is a saturated solution of sod. sulphide? This is not given in the table in the "Almanac."—C. E. F. N.

If the film has been strongly toughened beforehand it will not be so easy to make it adhere. We have usually found a thin solution of gum, applied to the plates and the latter dried, quite sufficient. No pressure should be necessary, the film must stick of its own accord. Our stripping solution is:—Methylated spirit, 25 oz.; water, 1 oz.; glycerine, 1 oz.; to each ounce of which from 6 to 30 drops of hydrofluoric acid is added. This solution is simply spread over the dry negative, and, after a minute or two, the freedom of the film tested by running a thread of silk stretched on a cane bow. 2. The sulphide is very soluble, but we do not know of accurate figures. We should think 1 part in 2 parts of warm water will give a saturated solution on cooling.

DRY MOUNTING.—I should like to know where I can buy the dry mounting machine (French patent). I should like to know the address in French (Paris).—J. VANDER DYK (Rotterdam).

Derepas Freres, 99 and 101, Rue St. Honoré, Paris.

H. P. (Denmark Park).—Thank you, but we are unable to use.

WORKING-UP CARBON MINIATURES.—1. I should be glad to know what powder can be used to work down too heavy shadows of the carbon on ivory before commencing to work-up in water colours. 2. Also if there is any preparation to fix the colours when the miniature is finished.—WANT-TO-KNOW.

1. An artist's scapel (a retoucher's knife) is an efficient instrument, and, if skilfully used, superior to any rubbing-down method, unless the parts to be reduced are eye or mouth shadows. For rubbing-down use absolute alcohol and tripoli powder, applied with a pledget of cotton wool; or, if very small portions have to be lightened, use a flat-pointed stick

covered with two thicknesses of lint at the end. A more rapid, but less safe, method is to use cuttle-fish powder in place of tripoli. 2. If a slight enamel-like finish is not objected to, use a varnish composed of celluloid (clean film clippings) 1 drachm; amyl acetate, 8 oz. Otherwise, use same varnish one-quarter strength. Apply thinly and rapidly in one direction only with a rather large, soft brush. A second coat may be applied when the first is dry if desired.

KOHINOOR PAPER.—Can you give me the name of the firm supplying this matt paper?—GEORGE FRANKS.

We are unable to say.

T. H. DUNN AND OTHERS.—In our next.

OLD CROW.—We should call indian ink a brown-black. If you find that the m-phenylenediamine bath gives you brown-blacks we should advise a short immersion in a combined toning and fixing bath. We have never obtained blue-blacks with it, and think that if you immersed the prints in salt and water prior to toning you would get pure blacks.

L. AXWORTHY.—There is no doubt that the stains are due to the prints having been touched with hypo-contaminated fingers; in fact, so distinct are these marks that you might almost determine at once whose fault it was by comparing the "stains" with the finger prints of those who handled the prints.

CHARLES MARSHALL.—There is little to choose between the two. The maker of the former would adjust a filter to any particular plate.

J. WILLIAMS.—Usually considered 1 oz. in water to a total bulk of 9 ozs. This is equivalent to 1 gr. in 10 minims.

S. M.—We should say that the party who commissioned you to attend and photograph the group is responsible for payment. Surely you know who this was.

PERMISSION TO PHOTOGRAPH.—Should esteem it a favour if you would tell me where permission can be obtained for the photographing of Nelson relics at Greenwich.—J. J.

The Secretary of the Nelson Centenary Exhibition, now open at the Royal United Service Institution, Whitehall, will probably be able to give you full information.

DEXTRINE PASTE.—Some weeks ago you published a recipe from your correspondent "Derbyshire" for a dextrine paste. I have made it up exactly in quantities named, and found it would not keep more than about a week. I should be glad if you would kindly inform me of some more sure method.—E. J. P.

Are you quite sure you used the right materials? We have had no difficulty in keeping a paste made to this formula, for six months or more. It has to be very well boiled before setting to cool.

BURTON.—We believe the plates are still obtainable from the large dealers, such as Fallowfield. Almost any of the commercial "iso" will give similar results.

***** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

A Misnomer. What is the fading of a photograph? Is the question unnecessary? Are we not all too familiar with the "fading" of photographs? A photograph which has undergone any change whatever is said to have faded, whereas there is really no fading at all in the true sense of the term. Many gelatine prints, owing to improper washing or fixing, become yellow in the lights, yet the image itself is really as vigorous as at first. That cannot be classed as fading. Platinotypes that, from careless manipulation, have had some of the iron salts left in the paper turn yellow in the lights, and, again, they are said to have faded. They have really not done so; the image is all there in its pristine vigour, and it is only necessary to dissolve out the iron, and the picture is as good as at first. Take, again, the case of a Daguerreotype. When the image has become partially obliterated with tarnish it is usually said to have faded, while it has done nothing of the kind. The silver plate upon which it is has simply become tarnished, and if the tarnish be cleaned off, the image will be found as it was when the picture was first taken. Indeed, a Daguerreotype is the most permanent of all silver pictures. One frequently sees at railway stations and other places, where they have long been exposed to strong light, photographs that have darkened by the action of the light. The lights have become of a pale purple tint, and the image generally considerably darker than it was at first. This is often called fading, though the picture is really much darker than it was originally.

* * *

A Caution to Retouchers. We think of Mr. Henry Arthur Jones's housekeeper, who told "the absolute and entire truth—under the circumstances," when we look at many examples of the retouched portrait. In the use of the pencil and knife, the photographer is thoroughness itself. No doubt he will tell you he is obliged to be; but we prefer to think there are signs that the old ideas as to a perfect portrait being that from which all signs of age or suffering have been obliterated, are undergoing a change. One does not usually look in the ladies' columns in the daily papers for guidance in such matters photographic, yet the extract which we quote from the "Globe" of last week may have its lesson for the portrait photographer:—"Once I was shown a woman who had got rid of wrinkles—how no one knew—and a most pathetic sight she was. Her face looked old, but that wasn't the sad part: it looked flabby and characterless, and the eyes seemed as if in a mask. After all, nature is a past mistress in her own line, and the women do most wisely who trust her. If she puts a wrinkle in the face of a brave, bright woman it means

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1906.

EDITED BY GEORGE E. BROWN, F.I.C.

The forty-fifth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1st. This year's ALMANAC reached a total of 1,612 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1906 will also consist of 25,000 copies.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1906 will be modified to make it more than ever the book of universal photographic reference. The editorial article will deal very completely with the important subject of

PHOTOGRAPHIC COPYRIGHT,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The ALMANAC for 1906 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and wherever practicable new features of an informative nature will be added.

The text and advertisement pages of the ALMANAC are now in the printers' hands, and our publishers ask us to state that proofs of all matter are being despatched day by day, and should be returned with all convenient rapidity.

something, and its artificial eradication leaves a vacuum which nature abhors inwardly and outwardly." We know we shall be told that over-retouching, if a fault at all, is a good one, and that to tell the truth in a photograph of a sitter beyond middle life is the way to drive customers from a studio. Yet we would rather take the point of view of the person who does not prefer a life-like picture "with all his imperfections on him" to the smooth nothingness of the portrait as retouched. We speak of extremes, though we know there are intermediate degrees which, without being gross violations of the truth, are not unpleasing to the sitter. We would wish to see the tendency towards a minimum of retouching grow stronger in every rank of professional portraiture.

* * *

A Show-case Hint.

One thing which seems to be much neglected in this country is the seasonableness of the specimens exhibited in show-cases. The weather we have had during the last week or two has been sufficient to remind us that winter is at hand, and it seems a little incongruous to see show-cases filled with pictures of persons clad in light summer costumes. We recently saw some large show-cases filled with really good pictures; but the whole of them were persons in summer garb, while those who stopped to look at them were clad in furs, or quite winter clothing. The specimens, good as they were, seemed quite out of keeping with the season. Had they been in autumn or winter costumes, such as people are now wearing, they would, doubtless, have attracted far more attention. Those who exhibit specimens in show-cases and shop windows will do well, just now, to replace any of the description just alluded to, by others in winter attire. Furs, and winter clothing generally, lend themselves well to photography, and favour the production of a good winter specimen case.

* * *

The Responsibilities of Owners of Photographic Premises.

A case which was briefly reported in our last issue serves to illustrate the responsibilities of those who occupy the upper portions of premises. It seems that a tap in one of the defendant's rooms was left running, while the outlet pipe from the sink was choked up, and, as a consequence, the floor below became flooded, and much damage was done. For this the photographer was sued in the County Court, and had to pay some sixteen or seventeen pounds by way of damages, and costs in addition. For the defence it was urged that the stoppage of the sink pipe was caused by the act of a caretaker who emptied some dirty water in the sink. That defence did not, of course, avail, as the tenant of the rooms is responsible for what occurs in them. It is no defence to say that the owner is only liable for what he or his employees may do, he is also responsible for what anyone else, to whom he gives access to his rooms, may do, and it is right that such should be the case. The owner is responsible for anything that may be done in his premises, and it is his business to see that nothing in the shape of injury is done to the property of those living underneath. For example, if the roof of the studio is in such a leaky condition that the water comes through, and does injury in the floor below he is liable to make the damage good. It is his business to see that his part of the premises causes no injury to others. Those whose workrooms are situated at the top of the house should see that the outlets from the sinks are always clear when water is left running for any length of time, or flooding and other troubles may arise. Where prints are left unattended in running water it is well to have a wire-guard over the waste pipe so as to prevent a print

that may float out getting over the opening, and by blocking it up cause an overflow.

* * *

Cold Weather and Imperfect Fixation.

We were recently shown some prints, with yellow stains, in patches, which the producer could in no way account for though they were clearly due to imperfect fixation. It was said that the prints were left the usual time in the fixing bath, and there was no doubt that was the case, but evidently the temperature of the solution had not been taken into account. Fortunately in the fixing of negatives there is a safe guide as to the course of fixation. If the plate be left in the bath as long again as it took for the bromide to disappear, however long that may be, it may be assumed that the negative is properly fixed. With prints we have no such guide, and therefore greater care and judgment is necessary in cold weather than in warm. When hyposulphite of soda is dissolved the solution is very many degrees colder than the water used in its solution. Even if that is warmed it very soon cools down when used in a cold room, a fact which is not always taken into consideration. In weather such as we are now experiencing a much longer time must be allowed to ensure the perfect fixation of prints. In the case of weak baths, double the time given in summer will be none too long, and the prints should be kept moving all the time. When the work is entrusted to young lads or girls and the solution is unpleasantly cold, the prints are not always kept turning about, the result is yellow patches such as those on the prints which suggested this note.

* * *

Glittering Accessories.

The difficulty of keeping furniture used as an accessory in a portrait from attracting more attention than it ought to do is very frequently felt, especially by the less-experienced workers. A great deal depends on the class of furniture used and its condition. Highly polished mahogany or walnut chairs are sure to reflect the bright light used in a studio, and to produce a multitude of sparkling catch lights. Upholstery of a light colour or containing patches of light or of blue, will frequently give resulting photographs which are spotty from a pictorial point of view. The late Valentine Blanchard used to go round the studio each week, after the charwoman had beeswaxed all the furniture, and with a piece of fine sandpaper dull the polish. This suggests that furniture for a studio might be ordered unpolished, or the woodwork merely oiled and slightly waxed. Not only will there be an absence of spotty brilliant high lights, but the furniture will photograph better, roundness and detail being more easily secured. It will be within the experience of most of our readers that the effect obtained with highly-polished furniture is similar to that got when photographing polished silver articles. Such objects present the utmost contrast of light and shade. With regard not only to the upholstering of studio chairs, but also to any fabrics employed, care should be exercised in their selection, bearing in mind the photographic value of the various colours.

* * *

Photographing Furniture.

The points touched upon in the preceding paragraph naturally lead to the question of producing photographs of furniture either for advertising or catalogue purposes, or, in the case of antique furniture of special value, for record work. Where single articles or suites are photographed for illustrating catalogues, a thing frequently done nowadays, it is much better to get the manufacturer to leave the goods unfinished until the pictures are taken. If this

cannot be arranged, or if, as in the case of antique furniture, it is impossible, the most satisfactory results will usually be obtained by photographing out of doors in a rather dull light. Any strong reflections will be no brighter than they would be if the work were done in a room or studio, and the shadows will be much better illuminated by the open light. The use of orthochromatic plates is hardly necessary unless the colours of the upholstery are such as to require it. In some cases, as where furniture is inlaid with satinwood, box, or kingwood the yellow colour of the wood may need a colour sensitive plate and a light filter; but for rosewood, mahogany, and so on, the ordinary plate will answer all purposes. It may be well to point out that with wood of a very figury nature, such as the speckled and burr walnut veneer used on many pianos, the adequate rendering of the figure of the veneer is important. This figure rarely shows so well before polishing as afterwards, and the work should, at all events, be oiled or commenced polishing before the photograph is taken. The slight polish, often called wax polish, however, is sufficient to bring up the grain or the figure without producing bright reflections.

* * *

Three-colour Work and "Irradiation." The address of Mr. Howard Farmer, partially reported on another page, and to be completed in our next issue, has the laudable object of bringing the three-colour process into a state by which it may be regularly worked in the ordinary way of business. Mr. Farmer's view is that this will be done by introducing "the irradiation system" of working. If this prove to be correct we should be glad to know from Mr. Farmer, or anybody else, precisely what is meant by "working by irradiation," and precisely how this method safeguards the processes of making three-colour negatives from inaccuracy. All we can discover on the subject is the paper by Messrs. Farmer and Symons in "The Photographic Journal" of August in last year, and we must confess that in the description there given of the process for the making of screen negatives for half-tone work, we cannot discern the possibilities which appear to impress Mr. Farmer so deeply in their application to negative for tri-colour pigment printing. In half-tone work, at any rate, we have yet to be convinced that "irradiation" will do more than the well-known system of the "optical V," or is more amenable to obtaining a predetermined result.

THE ASPECT OF THE RECEPTION-ROOM.

PHOTOGRAPHY as a profession depends for success on many different factors, ranging between the two essentials of good work under the skylight, and good business management throughout. Of these—heretical though it may seem to say it—the second essential appears to be the more vital one, for while many men capable of doing high-class work have come to grief over business mismanagement, there are more than a few men who have achieved undoubted success in spite of the fact that they turn out an inferior grade of work. We do not advance this condition of things in any advocacy of a low standard of work, but rather in order to emphasise the vital necessity of a good business organisation. To those who have not experienced the benefits of a thorough business training, and many photographers unfortunately come in this category, there is something formidable in the very words "system" or "business." Such men fail to grasp the simple fact that a business system is adopted merely for the simplifying and checking of work, and not in order to

add to its difficulties. In no department of the studio is this business capacity more essential than in the reception-room, for it is here that customers receive their first impressions, and where they decide the extent and value of their orders. The photographer himself may see to the ordering of supplies, and keep a careful check against any "leakage" in plates or chemicals, but the every-day work of the reception-room must be deputed; and the man is fortunate who can place it in good hands. An interesting object lesson has recently come under our notice in the studio of a friend who used to patronise our advertising columns with an offer of a permanency to a reception-room lady who could undertake spotting and retouching. He had a constant succession of ladies, with none of whom he could agree; either they were hopelessly incompetent (his statement) or they wanted too much money, or—well there was always some reason for a break, and the advertisement was sure to reappear. Twelve months ago he grasped the fact that he was not likely to get what he wanted unless he paid fair wages; of course, he might easily have paid a good price and yet not have met with the right girl, but as luck would have it he got exactly what he required at the first attempt. She began by managing her reception-room, and gradually and quietly extended her influence until it was felt in the furthest corner of the dark room, and among the printing frames; for one of her first lessons was promptness. She saw that people were often anxious to see their proofs as soon as possible, and she promised them for some early and specific date. Some photographers like to promise for "next week," but she usually sent out rough proofs on the second day, and always did so if they were promised. Her desk was a model of neatness, and everything except the matter in hand was put away. If the books were in use they, and nothing else, were on the desk, and they always were put away before the spotting materials came from their drawer. These important matters are in a measure minor matters; the real test is the amount of cash which accrues from orders. Many of the customers who come to the studio have a fairly clear idea of what they want, but some of them come without having arrived at a decision, and in all of them there are chances of larger or smaller orders according to the manner they are dealt with. A tactful receptionist does not discriminate unpleasantly between the working woman and the woman of wealth, but is equally considerate and attentive to all. The poor person who wants six cartes, silver-prints, ought, if she cannot afford more, or more expensive prints, to go away feeling that her choice is the best one that she could possibly have made, and not with a feeling that the work which is beyond her purse is better. Even where people can afford the higher priced work it is sometimes good policy to first show them the cheaper work, and from it work up to the platinotype or carbon. Many people who cannot afford the more expensive processes may be persuaded to pay an extra price for fancy mounts, which are usually good value, and have the advantage of giving good appearance for their cost. It is easy for people to drift into a studio and decide that they like the work and will call again to arrange a sitting, but such callers have a knack of forgetting; and so the smart receptionist always endeavours to book an order and arrange for a sitting at the time. Wherever it is possible—and always in the case of a stranger—she secures the cash with the order. A vexed question is the one of resittings, for some photographers hold somewhat strong views on it. Some customers are unreasonable, but there are many reasonable people who honestly think that the proofs submitted to them are unsatisfactory. It is often both pleasanter and better business to please the customer

with a resitting rather than to alienate support by standing up for rights too rigidly. We have based these remarks on a specific reception-room, and they should be read as suggestive rather than absolute, but enough has been said to emphasise the importance of a too often neglected side of business. In a future article we will

probably return to the business aspect of photography more particularly the question of needless waste; for the present we have achieved our purpose if we have clearly pointed out that business may be either helped or hindered in the reception-room, before ever the sitter gets under the skylight.

A METHOD OF COMBINING SEVERAL FIGURES IN ONE NEGATIVE.

PROFESSIONAL photographers are asked to do some strange things at times, and one of them is to take a head or figure from one negative and put it in another. It is not so impossible as it may seem at first. But a great deal depends on whether the figures are the same size and lighting. Sometimes when several plates are exposed on a family group, in each negative there is sure to be one figure, or face, not so good as in one of the other negatives, and the client will say, "Now if you could only take the head of that child and put it into the other photograph, it would be so much better." Or perhaps it is desired to introduce the photograph of a member of the family who is on the other side of the world, into a group, and a print is supplied. Even this can be done, but it is a little more complicated. Or, perhaps in a wedding group one important figure may have moved, and must be replaced, perhaps from another negative, or perhaps a special negative has to be made. If so, great care must be taken to get the size and lighting to correspond with the other figures in the group.

The Old "Cut Out Print" Method.

The old method of introducing another figure was by combination printing, but few printers would be found nowadays who could do this work, and as bromide and carbon printing is practised so largely, in which there is no visible image, combination printing would be impossible without some elaborate method of registration. Enlargements may also have to be made from such groups, and for such things a single negative containing all the figures would be necessary. The simplest method would be to make silver prints from the negatives and mount the large group and then paste the head, or figure, to be added in it, place on the large print, and then cover the whole. Such a method is best when a large number of figures (as a composite group) has to be dealt with, and it is often used in some of the so-called "comic papers"; but, for the average portrait photograph it is not so suitable. The resulting negative produces prints that are seen at once to be copies of a composite print, while the method I am about to describe, if neatly carried out, gives prints which show no signs of any manipulation, and may be enlarged or printed in any process.

A Negative Method via Stripping.

It is, briefly, removing the head, or figure, from one negative and putting in the other. The first thing to be done is to make a good transparency from each negative to be manipulated lest anything should go wrong; then all varnish and retouching medium must be carefully removed from both negatives, and it may be advisable to toughen the film with alum—chrome alum is more effective than the common potash alum. We will call the negative to which the figure is to be added No. 1, and the negative from which the figure is to be taken No. 2, and we will suppose that the head of a child has to be changed. We take No. 1, and, with a sharp knife, cut a line round the head and neck, taking advantage of the lines at the top of the dress to conceal the joins; the film *within* the line must then be scraped away till the glass is quite clear: then a little pure thin gum is taken on a small brush and painted over the patch of clean glass, and the negative is put aside for a few minutes to dry. Now place it in a retouching desk and lay

negative No. 2 over it, so that the clear patch of No. 1 is exactly under the part of No. 2 that is to be transferred. Next cut a clean line with the sharp knife through the film of No. 2 to exactly fit the bare patch of No. 1, and scrape away the film *outside* the cut, to isolate the piece to be removed. Then mix some methylated spirit, three parts, with water, one part, and into an ebonite or guttapercha cup put a few drops, say, three or four, of hydrofluoric acid, and pour into it about half an ounce of the mixture of spirit and water. Lay negative No. 2 on a fairly flat surface, and with three small slips of wood, tapered to wedges, level the negative, and pour some of the dilute acid upon the part to be stripped.

Points in Manipulation.

In a few minutes the edges of the film may be tried with a thin slip of wood—a match shaved thin at one end will do very well. If the edges are free from the glass the film may be folded over towards the centre and laid flat again all round to ascertain whether the piece of film is quite free. If quite loose, some of the spirit should be poured over to moisten it and to wash away the acid, and a piece of thin white paper, such as foreign notepaper, is laid on the film and gently pressed upon it, and then carefully raised, when the piece of film should adhere to the paper. If it does not, the paper should be again gently pressed down and lifted at the edge again until the edge of the film can be seen. Now, a little touch of the thin slip of wood will raise a bit of the film from the glass and make it stick to the paper, which should be raised very slowly bringing the film with it. The paper with film attached is now laid down on negative No. 1, so that that piece of film fills the gap prepared for it. The top of the paper is moistened with the spirit and water and carefully raised so that the piece of film is left sticking in its place on the negative. It may need a little coaxing with the slip of wood to do this. In ten minutes the composite negative is ready for the joins to be touched up, where necessary, with scraper and spotting brush. It is important that the two negatives should be equal in printing density, but slight differences can be adjusted with matt varnish, etc.

In handling hydrofluoric acid, even when diluted, it should on no account be allowed to touch the skin, especially the tips of the fingers, because, though no pain or discomfort may be felt at the time, in a few hours the finger nails are attacked by a most horrible aching, which lasts for hours, and which nothing seems to relieve, and bad ulcers may form under the nails. The strong acid will produce very bad sores.

On one occasion I had to take a group of four generations, but the eldest member was in Australia, and only a silver print was available. I therefore arranged the other three so that a space was left for the fourth, and I then copied the print to the necessary size, and introduced the figure by the method described; but, unfortunately, the composite negative was accidentally cracked. I then stripped the whole from the glass and laid it down on a fresh one, but, unfortunately, the film refused to dry flat, and wrinkled all over in the most horrible manner. It was again stripped, and again would not go flat, so I prepared a large glass and soaked the film off in

water and floated it on to the new glass. Fortunately the gap in the film expanded to the same extent as the piece to fill it, which was coaxed into its place by the aid of small brushes, and a successful result at last attained after so many accidents. This method, of course, needs great care and exactness in

fitting the parts, and it would be a good plan to gain a little experience on waste negatives. I have seen a panoramic view made in this way, from two 15 by 12 negatives, so successfully that the joins could not be detected in the print.

HAROLD BAKER.

THE EXPOSURE IN ENLARGING.

The practical enlarger is well aware that there is scarcely any other branch of photographic work in which correct exposure is of so great importance. There is very little power of modification during development, but upon the correctness or otherwise of the interval between removing and replacing the orange cap depends the final character of the enlargement—whether it is to be flat, grey, and washed out; hard and chalky, with excessive and glaring contrasts; or, what the enlarger fervently desires, but does not invariably obtain, a vigorous and effective picture, with velvety blacks, pure whites and soft, full gradation.

Daylight Enlarging.

Enlarging by daylight has been much maligned, on the score that the continual changing of the light gives rise to great inconvenience and difficulty in estimating the exposure. The writer can at least claim to have experienced this objection at its very worst, having for a long time been obliged to use for the purpose a window where the sun shines during the greater part of the day, so that every passing cloud and temporary emergence or disappearance of the solar luminary gives rise to the most startling variations in the light. And yet, by the uniform use of an actinometer, no real trouble has been experienced in securing satisfactory results, while one marked advantage has been found, namely, the great rapidity of exposure and the ease with which even the densest negatives can be worked. The plan usually recommended, of having an inclined white reflector outside the window, was in this case, of course, impracticable. Instead, a sheet of white tissue paper, free from creases, was attached by the edges to the aperture in the window shutter, by which means a well-diffused and even light was readily obtained. The paper must be several inches away from the negative, so that no grain or fibre is focussed. Wherever the light is sufficiently strong, this, or a sheet of fine ground glass, may be strongly recommended as a great improvement on the inclined reflector, which is awkward to keep clean, and frequently gives uneven lighting.

Factors Affecting Exposure.

As a little consideration will show, there are six factors by which the exposure is regulated—the amount of light available, the character of the negative, the aperture of the lens, the size of the enlargement, the rapidity of the paper, and the constitution of the developer. By keeping the last two constant they may be eliminated as disturbing factors, although it is very easy to ascertain the relative rapidities of various makes of paper and the different peculiarities of developers, so as to allow for a change in these whenever necessary. The aperture of the lens, too, may be kept uniform as far as possible, excepting when a very thin or very dense negative seems to call for a lesser or greater amount of stopping-down, since this is practically the only means of regulating the light in daylight enlarging, unless, indeed, extra thicknesses of tissue paper are interposed between the negative and the window aperture—a plan which cannot be advised.

Testing the Light.

The great point in daylight enlarging is to be constantly testing the light, doing this also while making the actual exposure. For this purpose an actinometer is required; the watch form, with a couple of small standard tints placed against an opening in the dial, under which fresh paper can be drawn as

desired, being the most suitable. The best method of using this is to have an extra aperture in the shutter, provided with a hinged lid or sliding door. Over this is fixed a projecting bracket about a foot long, with a hook or wire arranged so that the actinometer may hang level with the aperture. The latter must be screened or curtained to prevent any light reaching the enlarging bench or easel, but in such a manner that the actinometer can be readily watched by the worker from within the room. To use this arrangement, a fresh piece of paper is brought under the opening of the actinometer, and, the sliding door of the small aperture being drawn up, the time taken by the paper to match the full tint is carefully noted. We will suppose this to be 20 sec. At or about the same time, a test strip of bromide paper is being exposed for the enlargement, and the section which gives the best result on development is, let us say, that which has received an exposure of 30 sec. When we come to exposing the actual enlargement the light has perhaps changed, but by making a fresh actinometer test, simultaneously with starting the exposure for the enlargement, no difficulty will be found in allowing for this. The actinometer this time, for instance, takes 40 sec. to reach the full tint; a simple proportion sum, therefore, gives us

$$20 : 40 :: 30 : 60 = 1 \text{ min.}$$

as the correct exposure now necessary. It is much more convenient if the enlarging objective is fitted with a pneumatic shutter and bulb, since the bulb can then be held in the hand while watching the actinometer, and the exposure given simultaneously, or instantly after. When the light is dull, the quarter-tint may be used instead of the full tint, making the necessary allowance in calculating.

Character of the Negative.

The practical worker will habitually remove many otherwise unavoidable complications from his path by classifying all his negatives, according to their destiny and other characteristics. This is readily done by testing the printing time of each with one of the simple print meters now obtainable. The information so gained should be written on the margin of the negative, or on an envelope. When enlarging, directly the correct exposure has been noted for a given negative, a reference to the "print meter number" of any other negative will at once give the exposure required for it, under the same conditions of light, tested by the actinometer as previously described. Another useful method of ascertaining the character of the negative is to make a contact print on bromide paper, preferably of the same make and rapidity as that on which the enlargement will be made. This should be done by some standard artificial light. The exposure necessary to secure a satisfactory print is carefully noted, and affords at once, by comparison with that required by other negatives, an indication of the time which must be given in making the enlargement, the calculation being arrived at as before stated. The exposure for the contact print may be conveniently called the "bromide print factor."

Size of Enlargement.

There is a very common fallacy regarding the ratio in which the exposure must be varied for different sizes of enlargement. Many workers fancy that an enlargement four times the size of the original—i.e., twice its linear dimensions—will require four times the exposure needed for a copy

of only the same size, on the theory that the light is spread over four times the area, and is consequently only one-quarter as strong. This method of reasoning, however, takes no account of the fact that the value of the lens aperture alters according to the camera extension and the distance of the easel from the objective, and is necessarily quite inaccurate. The rule for finding the relative exposures for different sizes of enlargement is as follows:—Add 1 to the number of times of enlargement (linear), and square the product. Thus, for a copy the same size as the original the figures would be $(1 + 1)^2 = 2^2 = 4$; while for an enlargement of twice the linear dimensions of the original—for example, quarter-plate to whole plate—the calculation is $(2 + 1)^2 = 3^2 = 9$. The relative exposure, therefore, for the two-times enlargement is as $9:4=2\frac{1}{4}$; that is to say, $2\frac{1}{4}$ times the exposure required for a copy the same size will be necessary. (A useful table based on this formula will be found in "The British Journal Photographic Almanac.")

Influence of Developer on Exposure.

The exposure required for an enlargement will vary with different developers; that requisite with ferrous-oxalate, for example, being considerably more than with amidol or metol and hydroquinone. It is therefore indispensable in adopting any scientific system of exposure calculation, to adhere to the same description and composition of developer, only diverging from this under exceptional circumstances and for special reasons. It will, however, be distinctly useful to make a few experiments with various developers, keeping the negatives and other conditions the same, in order to ascertain the different exposures necessary, and the ratio which these bear to each other.

Enlarging with Artificial Light.

A very large proportion of trade enlarging is done by artificial light, which is preferred on account of its greater constancy. The factors affecting exposure are here somewhat different. In the first place, great care must be taken to keep the

illuminant, whatever it may be, as far as possible at a fixed brilliancy—and this is by no means so easy as might be thought. With the arc light, it is a question of properly regulating the carbons; with incandescent gas, of replacing worn-out or broken mantles, and trying to secure a regular pressure; with paraffin of turning the wicks to a given height and seeing that they are periodically trimmed and cleaned. The Nernst-Paul electric lamp, the mercury vapour light, acetylene, spirit, limelight, and other forms of artificial illumination have all their special characteristics, which must be thoroughly studied and understood, in order to avoid any difficulties in exposure calculations, which would inevitably arise through any great variations in the strength or actinic quality of the light. It is worth while mentioning that the exposure with an incandescent gas mantle will differ good deal according to the blueness or yellowness of the light given by the latter—a matter which should be seen to in chasing. It must be borne in mind that if a condenser is used the diaphragm will no longer have the same effect in reducing the illumination, as in daylight enlarging, but may or may not cut off part of the image, according to the position of the point where the converging rays from the condenser cross and spread out again.

Testing Artificial Light.

In conclusion, it may be remarked that the actinic strength of any artificial light may be tested, without removing it from the lantern, by opening the door and making a contact print in bromide from a standard negative, which must be kept for the purpose, at a given distance from the light; keeping the paper and developer constant. The print is exposed in sections and the time of exposure for the best-exposed portion noted. By doing this every time the lantern is lighted up, using the same negative, distance, etc., the information obtained from the resulting sectional print, compared with that first made, will show if the light is above or below the standard, and a suitable allowance may be made accordingly.

A. LOCKETT.

THE WEEK IN HISTORY.

Talbot's Photographic Engraving.

It is exactly fifty-three years ago that Fox-Talbot applied for the patent (No. 565) in his process of photo-engraving. His specification is of historical importance because, as I pointed out a week or two ago, it is apparently the first published statement of the behaviour of gelatine when exposed to light with bichromate. Talbot's patent claim is for the above as a new process, although he does not appear to have discerned the importance of the reaction in other directions. His photo-engraving process was practically the modern photogravure. He coated a steel plate with gelatine and potassium bichromate, exposed it under a positive, and after development and drying etched the plate with bichloride of potassium. An important part of his process was the breaking up of the image into a grain with a piece of crape or gauze, exposing the plate behind this latter before or after the usual printing from the object. He also mentions the laying on the plate of an aquatint ground with resin powder.

The Last Phase in Carbon Printing.

I have already chronicled in these notes the two important steps in the carbon process following the early work of Poitevin, and one or two others, the first phase was inaugurated by Sir Joseph Swan, whose patented process of 1862 ("The Week in History," February 24, page 146) provided for the development of the tissue from the back by transferring the print to paper coated with indiarubber, the collodionised surface of the tissue itself having been likewise rubber-coated.

Phase 2.—In 1869 Mr. J. R. Johnson ("The Week in History," February 3, page 86) found that the cementing with rubber was unnecessary. If the wetted tissue were laid on a glass or paper support, it sticks of itself and permits the soluble part to be removed by development in hot water. But the picture was thus inevitably reversed, and hence Phase 3, which commenced exactly thirty-one years ago on Sunday next, when Mr. J. R. Sawyer patented his "temporary support" to which the print was transferred for development, and from which it was afterwards transferred, unreversed, to its final support of glass, paper, etc.

The essential feature of Mr. Sawyer's temporary support was the combination of insoluble gelatine with lac and similar substances to form a bed on which the detail of the picture was held whilst in a moist condition and during development.

Mr. Sawyer's method of preparing the flexible support, as described in his specification, is as follows:—A solution of French gelatine is made, 5 per cent. or less for matt, 10 per cent. or more for a highly glazed surface. To this solution chrome alum is added as largely as possible, short of the gelatine becoming ropy, and the mixture coated on to paper by floating or from a machine. After drying and, preferably, hydraulic pressing, the gelatinised paper is coated with a solution of lac (the best button lac) in soda carbonate solution and again dried. It is lastly rubbed over with a preparation to make its surface repellent of water—viz., a solution of resin and white wax in turpentine.

HISTORICUS.

A NOTE ON ORTHOCHROMATIC PLATES FOR ASTRONOMICAL WORK.*

The usual spectrographic tests made for the purpose of determining the sensitiveness of "orthochromatic" plates are in general very much in error, owing to the means adopted for obtaining the negatives. The prismatic spectrum is altogether unsuited as a "standard"; first, because of the selective absorption in the ultra-violet (and even in the visible violet) when prisms of dense flint, or direct vision spectroscopes, are used; while, second, the irrationality of the particular prism employed must be determined before any correct comparative estimate of the spectrograms can be made.

In the use of reflection gratings there is likewise an element of uncertainty on account of the selective absorption—no two gratings

for which the plate has been specially sensitised. Consequently, there exists a considerable discrepancy in the curve of sensitiveness (even of the same plate) by different observers, no due allowance having been made for the increase in density towards the red, and decrease in the violet, consequent upon the prismatic irrationality already mentioned. It is, therefore, obvious that if the opacity of the red or yellow region be increased, while that in the violet be weakened, then due consideration must be given to this effect.

In the "sensitiveness-curves" appended to this paper, use was made of a transparent replica grating and the spectrum of the first order utilised. By means of a plate-holder furnished with rack and

Light-Units

1575

1024

giving spectra directly comparable with one another in so far as luminosity is concerned—and it is this point which chiefly concerns the photographic plate.

Prism and Grating Spectrum Tests.

The conditions governing a "standard" dispersion-piece are easily met by the adoption of a transparent diffraction grating manufactured as described by the writer [Mr. Wallace sends us this paper, which we shall shortly reprint.—Eds., B.J.P.], which is obviously free from abnormality due to differences in the material of which it is formed, or to the process employed in its preparation.

Estimates based upon the negatives of the prismatic spectrum are very misleading on account of the crowding together of the colours in the red end and the elongation in the violet, thereby giving an apparently greater proportionate action in the least refrangible hues,

pinion consecutive exposures were made upon various plates with duration as follows:—2, 5, 15, 30 seconds, 1, 2, 4, 8, and 16 minutes.

In some cases a supplementary exposure of 25 to 30 minutes was given in order that the action of prolonged exposure might also be noted. A reproduction of one such plate is shown herewith.

The Method of Plotting the Results.

In plotting the sensitiveness-curve a print was first made on Solio paper from one of the plates and that exposure selected which represented the highest allowable printing opacity—that is to say, that spectrum which was so opaque in the region of greatest sensitiveness that it was only with difficulty that the Fraunhofer lines would show on the print. This opacity was found to be represented by a light action of 256 units on a negative obtained from exposure behind a revolving Hurter and Driffield sector-disc, on the same plate, developed for the same length of time. On every other plate, therefore, that spectrum was selected for estimation whose greatest region of

* This paper from the "Astro-Physical Journal" reaches us, as a reprint, from the author, who holds the position of photo-physicist in the Yerkes Observatory.—Eds. B.J.P.

opacity corresponded to 256 light units on a similar plate exposed by disk. The curve was then plotted on squared paper, where the ordinates represent amount of light action (in units), and the abscissæ, wave-lengths; the variations in opacity throughout the length of the spectrum being estimated by small patches isolated by an opaque screen and in juxtaposition with the various opacities of the sector negative, the aperture ratio of which is accurately known.

Comparative Values of "Selective Sensitiveness."

It will be noted that two of the curves rise above the limit of the squared field. This was rendered necessary owing to the very slight action in the red end of the spectrum as compared with normal exposure in the blue-violet. The heights of the blue-violet curves in these cases were estimated simply by the ratio between that spectrum whose exposure time equalled normal exposure (= 256 light units) and the time of the one selected for plotting, the opacity being much too intense for measurement.

It should be understood that these curves are representative only of

"selective sensitiveness," no consideration whatever being given to the relative speeds. Tests were made from the standpoint of the "Schwelenwerth" as being best suited to astronomical needs, where the principal point is to obtain developable action with the smallest light value. These tests for the plates plotted may be tabulated in the following results:—

Cramer "Instantaneous Isochromatic" ..	= 1
Seed "Landscape Orthochromatic"	= 3 per cent. less.
Lumière "Ortho A" }	= 7 per cent. less.
Lumière "Ortho C" }	
Lumière "Ortho B"	= 14 per cent. less.
Cramer "Trichromatic"	= 40 per cent. less.

Acknowledgments are due to Mr. H. B. Lemon for able assistance in this work, and also to Messrs. Lumière, Cramer, and Seed, who kindly furnished the necessary plates.

ROBERT JAMES WALLACE, F.R.A.P.

THE ABSORPTION SPECTRUM AND FLUORESCENCE OF MERCURY VAPOUR.

[A Paper communicated to the Royal Society, and printed in the "Chemical News."]

HAVING undertaken the investigation of the absorption spectra of metals in a state of vapour, the first substance examined was mercury, and as the results are interesting I have deemed it advisable to make them a separate communication to the Society. F. P. le Roux describes the vapour of mercury as having a bluish colour ("Comptes Rendus," 1860, vol. li., p. 171), and, according to R. J. Strutt, it transmits a feeble steel-blue colour, but the absorption coefficient is small ("Phil. Mag.," 1902, [6], vol. iv., p. 596; and 1903, vol. vi., p. 76).

Experimental.

The substance to be volatilised was contained in a flask of Heraeus' quartz-glass, with a side tube to the neck from which the metal may be distilled and condensed. To the side tube a water-jacket is fitted, through which a constant stream of water may be passed if necessary. The rays from the condensed spark of a pair of lead-cadmium and tin-cadmium electrodes were passed through the flask and on to a cylindrical condensing lens of quartz which focussed the rays on to the slit of a quartz spectrograph.

The mercury to be used was first purified by distillation. The photographic plates used were various, such as "Rainbow Fast" Warwick plates, Lumière isochromatic yellow-green sensitive, and Cadett and Neall's "Lightning Spectrum" plates. The mercury vapour in the flask was at a pressure of 847 m.m., the barometer standing at 763 m.m., but the vapour was under a pressure of a column of 84 m.m. of mercury above that of the atmosphere. The temperature was about 360 deg. C., the boiling-point at 760 m.m. being 357 deg. The volume of the vapour was 31 c.c., and its weight was calculated to be 0.133 grm. The thickness of the layer of vapour was 37 m.m.

Several photographs were taken and particular care was exercised so as to have both ends of the spectrum as well as the central part in accurate focus. The developer used was imogen sulphite.

The Absorption Spectrum.

The whole rays were transmitted from the red to a point in the ultra-violet where there is a tin-line at λ 2571.67. From there to λ 2526.8 there is a very sharply defined and intense absorption band, somewhat degraded on the side towards the red; beyond that the rays are transmitted with full intensity to a wave-length about 2000.

The Fluorescence.

When the mercury was boiling briskly the whole side of the flask nearest to the spark was lighted up with a green fluorescence; this penetrated about one-third of the space within the flask, and lighted up the interior. The quartz-glass itself was not fluorescent in the slightest degree.

When all the liquid mercury had become converted into vapour, the temperature no doubt rose above that of the boiling mercury, the vapour was quiescent, and the fluorescence ceased. The interior of the flask was then quite dark. By shaking some of the condensed cold mercury down into the flask, the fluorescence was resumed directly the liquid boiled again, but the dropping of cold mercury into the heated vapour caused condensation, and only after the flask had again become filled with the mercury vapour was the fluorescence fully displayed.

When the vapour was rising from the boiling globule of mercury after the cold metal had condensed all within the flask, the vapour could be seen by its fluorescence to undergo condensation in the upper part of the vessel and descend to the hotter space below.

It occurred to me that the actual fluorescence might be associated with oxidation of the vapour, and that it appeared only when such chemical action was taking place, but subsequent observations showed that this could not be the case, because the temperature was above that when oxidation could occur at the time when the fluorescence was most brilliant, and when it most completely filled the vessel, and also when the mercury vapour had expelled all the air. When the temperature rose above the boiling-point of mercury and excess of liquid mercury and vapour had been expelled from the flask, the fluorescence ceased.

This fact leads to the inference that the fluorescence occurs only between a lower and a higher limit of temperature. What these small differences really are I had no means of determining. Having established the fact that the property of selective absorption is possessed by small quantities of mercury vapour, it was resolved to ascertain whether the band showed itself in solutions of mercury compounds. As a rule the absorption spectra of compounds differ from those of the elements entering into their composition entirely, as in the case of the halogen compounds of the alkali metals; sometimes it is a question of degree, as in the case of the compounds

of the rare earth metals, in which similar bands are observed in different salts of the same metal, but in different positions, which vary with the molecular weight of the salts; and there are, still further, other instances where the absorption bands of the solutions are distinctly the properties of the salts, as in the case of the chlorides, bromides, and iodides of cobalt. The salt chosen for examination, because it is the most definite and most soluble, was mercuric chloride. It was examined in cells of 40 m.m. thick, diminishing to 1 m.m. in thickness. The solution contained in the same volume ten times as much mercury as the vapour which filled the flask, or 1.8 grms. of mercuric chloride in 31 c.c. of water; more dilute solutions were examined containing 0.18 grm. and 0.018 grm. No absorption band was visible on any of the spectra photographed, but there was a continuous absorption at the more refrangible end of the spectrum which regularly diminished as the quantity of mercuric chloride in the solution decreased.

Further details are as follows:—

1.8 grms. of mercuric chloride in a cell 40 m.m. thick transmitted all rays to λ 2702, in 1 m.m. to λ 2572; 0.18 grm. in a cell 2 m.m.

thick, transmitted all rays to λ 2265; and 0.018 grm. in similar circumstances transmitted very feebly to λ 2145.

The absorption band in the vapour of mercury belongs to the vapour and is accompanied by strong fluorescence between a certain maximum and minimum of temperature lying very near to the boiling-point.

In studying the fluorescence of solutions of organic compounds I have shown that it is necessary to use the ultra-violet rays and quartz apparatus, as it was found that fluorescence was associated very generally with a powerful absorption of rays in the ultra-violet ("Observations on the Origin of Colour and Fluorescence," "Chem. Soc. Trans.," 1893, vol. lxxiii., p. 245-256). It is a question still undecided whether the rays absorbed by mercury vapour as shown by the band I have measured reappear with a lowered refrangibility as yellowish-green light in accordance with the law of Stokes.

The spectra were photographed with all due care by my assistant, Mr. Douglas Mellon, A.R.C.Sc.I.

W. N. HARTLEY, D.Sc., F.R.S.

A CRITICISM OF THREE-COLOUR PHOTOGRAPHY.

[The following introductory lectures, by Mr. Howard Farmer, on the opening of the twenty-third session of the Polytechnic School of Photography on Tuesday in last week was delivered under the title, "Dots, or Coming Events Cast their Shadows Before." In substituting the description at the head of this page, we have kept still close to the lecturer's intention, which is an indictment of three-colour photographic processes, so far as they are intended for commercial use by professional photographers.—EDS., B.J.P.]

The object of my opening lecture this evening is to put before you certain truths in connection with the problem of photography in natural colours, and in speaking to an audience nearly the whole of whom are professional workers, let me say that the aspects of the subject to which I shall refer are exclusively those from the professional side. Colour photography has been theoretically possible for nearly half a century, and a great deal has also been accomplished from the practical side; but, speaking in the professional sense, which requires the production, with certainty and success, of so many copies of any subject brought to the studio, though many explorers are engaged in the search, they are still in darkness, and success, like a will-o'-the-wisp, continually evades them.

The Simplicity of Reproduction of Movement.

You have just seen, by means of animated pictures, various scenes and incidents as they appear in motion. You know as well as I do that these pictures are ordinary photographs, and that the means by which they become endowed with apparent life consists in taking a number of separate photographs, with very short intervals of time between each, and then projecting them, with similar intervals of time, one over the other and one after the other, upon the screen. Now the actual motions these photographs so admirably reproduce are infinite in their complexity—up and down, to and fro, in and out, round and round—with endless variations of speed and direction the objects move. You look with wonder at these moving and apparently sentient beings, but is not the simplicity of the means which enables them to be reproduced equally wonderful?

Let us examine for a moment the fundamentals on which the success of these reproductions are based. They are two in number:

Firstly, owing to what is called persistence of vision, it is not necessary for us to see every phase of a given motion. If we present to the eye sufficiently close steps or stages of the movement we do not recognise the gaps which are missing, and the motion appears continuous and complete.

Secondly, there is "the accuracy of the photographic image." By suitable mechanism, easy of operation, we can swiftly impress with accurately-timed sequence our thousands of images, in which

all the motionless objects are in absolutely identical drawing, and register with one another; and only the moving objects change, exactly as we see them in nature. I will ask you to fix in your memories for a short period these two things—(1) that the reproductions are possible by comparatively simple means; (2) that an essential element of success is the absolute fidelity, geometrically speaking, of the photographic image.

The Simplicity of Reproduction of Solidity.

Let us take another example. Here is a stereoscope, in which we have the presentation to the eye of solidity and relief—wonderful when first seen. Still more wonderful to me is the simplicity of the means employed. Imagine, if you can, the complexity of the form of a tree, with its leaves—of a cathedral interior with its carvings and mouldings—or of a crowd of people, and how are they reproduced? Simply by taking two photographs, from slightly different positions, and mounting them, so that they are presented to the eye as one picture—an inconceivable thing before you know something of the mechanism of vision—simplicity itself in practice. As in animated photography, there are two fundamentals upon which the success of the stereoscope depends: Firstly, upon binocular vision, which requires only two views, of the most intricate subject, to give it complete shape and solidity; secondly, the accuracy, geometrically speaking, of the photographic image. Again, may I ask you to remember for a short period these two things: (1) That a perfect rendering of relief is possible by means exceedingly simple in comparison with the original; (2) that an essential element of success is the absolute fidelity of the photographic image.

The Simplicity of Reproduction of Sound.

One lovely evening this summer I was sailing with friends up a beautiful river. There still exist on the South Coast one or two rivers practically in their original natural condition—no noise, no dirt, no houses, no traffic, no accessibility even except by water, beautiful forest trees on either bank, rushes, and wild birds. Such a river as this is the Beaulieu River in the New Forest. Imagine yourselves gliding along through such a fairyland of peacefulness, with nothing in sight but trees, water, and sky, and suddenly the

air is suffused with music, from a hundred instruments and with absolute loneliness yet surrounding us, there is the strain of music from the most gifted performers in the kingdom: Nature in her wild state, yet music which we inseparably associate with the highest centres of organisation and culture. Not all the wonders of the fairy tales which you read, in the "Arabian Nights," of your childhood surpass the magic of the effect, and the source of the music, as you already will have guessed, was a phonograph. Wretched thing, musicians will say, but if heard under the conditions I have stated they would also have been enchanted. When first heard we were fully a mile from the instrument, the sound being carried by the water, and we discovered it later on the deck of a large yacht, anchored several windings further up the river. But what has this to do with the subject of this lecture? It is another example showing that the means by which your senses convey to us infinite complexity and variableness may be extremely simple. The phonograph which had been used to record the music of the orchestra had simply cut a groove on a wax cylinder, the depth of which was proportional to the force of impact of the total of the sound waves from all the instruments at any moment. Can you conceive anything more complex than the mass of sound vibration from 100 instruments, with perhaps human voices added, and yet the little wax cylinder, quietly revolving on its spiral thread, allows without resistance the pointer of the vibrating diaphragm to cut a groove, the sinuosities of whose depth record the music? Nothing but a simple line forms a marvellously accurate record, and on reversing the action, by causing the waxed cylinder to itself excite the drum, the music is reproduced. I do not think it would be possible to find a better example illustrating by what simple means the effect of these complex actions can be recorded and reproduced for the gratification of our senses.

The efficiency of the phonograph depends also, like the cinematograph and stereoscope, upon two fundamentals: Firstly, upon the simplicity of the mechanism of the ear; secondly, upon the accuracy of the waxen record. The wax cylinder, soft and inelastic, allows the cutter to perfectly record the vibrations of the drum. The same sound, and position of instrument, *always* the same identical cut; just as with the camera, the *same* object, and position of camera, *always* the same identical image.

E. HOWARD FARMER.

[The conclusion of this paper will appear next week.—Eds. B.J.P.]

CATALOGUES AND TRADE NOTICES.

HARRINGTON'S CATALOGUE, the production of the well-known house of 386, George Street, Sydney, reaches our table as a bulky volume of 340 pages. Messrs. Harrington handle the current apparatus and materials, and their list evidences the inclusiveness of their stocks.

THE RUSSO-JAPANESE WAR.—Messrs. Sanders and Crowhurst, 71, Shaftesbury Avenue, London, W., announce the publication of lantern slides from the unique series of negatives made by Mr. J. Ricalton, for Underwood and Underwood. The set includes 200 subjects, obtainable as plain slides, at 2s. 6d. each.

The Service Photographic Society have extended their premises to include a show room directly on Holborn, immediately adjoining their present show rooms. Their new number is 293, High Holborn. In this show room they will periodically arrange a show of photographic goods. They are now showing during the present week an assortment of seasonable novelties.

"*Fotographia per Dilettanti*," By G. Muffone. An elementary text-book of photography, published by the firm of Ulrico Hoepli, Milan.

Exhibitions.

GRANGEMOUTH.

An exhibition under the auspices of the Grangemouth Amateur Photographic Association was opened last week in the Y.M.C.A. Hall, Grangemouth. The awards were as follows:—Gold medal in championship class—A. W. Hill. In landscape and seascape section, silver medal—James Burns; bronze medal—P. D. Nairn and R. Robinson. In the portraiture and genre work, silver medal—A. W. Hill; bronze medal—Jas. Hamilton. Flowers, architecture, etc., section, silver medal—S. G. Kimber; bronze medal—James Dunlop. In lantern slide section, silver medal—Rev. H. W. Dick; bronze medal—Robert Marshall. The judges were James Patrick, Edinburgh, and Archd. Campbell, Broughty Ferry.

ROTHERHAM PHOTOGRAPHIC SOCIETY.

The sixteenth annual exhibition of the Rotherham Photographic Society was held on Wednesday, Thursday, Friday, and Saturday, October 18-21, and attracted an increased number of entries, and very liberal patronage. In the open classes there were 237 entries. Messrs. C. Barrow, Keene, F.R.P.S., and T. A. Scotton, of Derby, again acted as judges, and made the following awards:—Class A, champion class (any photograph previously medalled in open competition)—silver plaque, William Clayden, "Tugging Home." Class B, portraiture and figure studies—bronze plaque, Thomas Heaps, Keighley, "The Artist"; bronze plaque, William H. Foxall, Tunstall, "A Jovial Monk"; bronze plaque, A. E. Coleman, Plymouth, "Binding the Wheel." Class C, landscape, seascape, and river scenery—silver plaque, John S. Atherton, Todmorden, "June"; bronze plaque, A. W. Cooper, Preston, "Autumn Mist"; bronze plaque, Fred Judge, Hastings, "September." Class D, architecture—bronze plaque, Alfred Roffey, Birmingham, "The Chapter House Entrance"; bronze plaque, J. Dunlop, Motherwell, "Peacefully the Shadows Guard Their Tomb." Class E, flowers, fruit, still-life, or other subject not included in the foregoing classes—bronze plaque, S. G. Kimber, Southampton, "Grasses"; bronze plaque, D. W. Kyle, Glasgow, "Crysanthemums"; bronze plaque, E. Seymour, Watford, "Hops." Class F, lantern slides—silver plaque, Rev. H. W. Dick, Manchester; bronze plaque, F. G. Tryhorn, Wavertree; bronze plaque, W. H. Goy, Battersea Rise; bronze plaque, E. Seymour, Watford. Members' section:—Class G, landscape, seascape, and river scenery—bronze plaque, F. A. Jordan, Doncaster, "On the Don"; bronze plaque, J. C. Cox, Rotherham, "By the Side of the Stream"; bronze plaque, H. C. Hemmingway, Rotherham, "Loch Fad." Class H, architecture—bronze plaque, J. C. Cox, Rotherham, "Beverley Minster"; bronze plaque, W. Firth, Rotherham, "To the Cloisters, Kirkstall." Class J, miscellaneous subjects, not included in the foregoing classes—award withheld. Class K, lantern slides (sets of four)—award withheld. Class L, best board of exhibits—J. C. Cox, Rotherham (withheld); bronze plaque, S. A. Carr, Rotherham. President's silver plaque for best picture by a member (negatives taken during 1905)—Miss Tillotson, Rotherham.

ISLE OF WIGHT PHOTOGRAPHIC SOCIETY.

The third exhibition of the Isle of Wight Photographic Society was opened at the Medina Hall, Newport, on Tuesday of last week. In the absence of the president, Professor Milne, F.R.S., Mr. Michael Maybrick, J.P., of Ryde, presided. The awards in the open classes were as follows:—Open class, landscape, seascape, and

river scenery—gold medal, "A Dusty Day," Arthur Marshall; bronze medal, "Tugging Home," Wm. Claydon; hon. mention, "The Old Parish Church," Fred Judge. Class B, portraiture, figure studies, and animals—silver medal, Dudley Hoyt; bronze medal, Bernard Moore; hon. mention, J. Patrick. Class C, architecture—silver medal, W. A. Clark; bronze medal, Victor E. Morris; hon. mention, S. G. Kimber. Class D (still-life, flowers, and fruit)—silver medal, E. Seymour; bronze medal, R. Burnie; hon. mention, Frank W. Beken. Postcards—bronze medal, Rev. C. T. Clark; hon. mention, A. W. Cooper. Lantern slides—silver medal, H. Wormleighton; bronze medal, V. E. Morris; hon. mention, S. G. Kimber.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes.

The following applications for Patents were made between October 9 to 14:—

CATATYPE PRINTING.—No. 20,372. Improvements in the reproduction of pictures, with aid of catalysis. Neue Photographische Gesellschaft, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London.

DEVELOPING.—No. 20,502. An improved apparatus for storing and developing photographic plates. Silvius Jean Stefaneson, 79, Frithville Gardens, Shepherd's Bush, London.

FOCAL PLANE SHUTTERS.—No. 20,528. Improvements in focal plane shutters. Magnus Niell, 88, High Holborn, London.

PRINTING FRAMES.—No. 20,563. Improvements in photographic printing frames. Ernest Christopher Alderton, 137, Osbaldeston Road, Stoke Newington, London.

APPARATUS.—No. 20,570. Improvements in photographic apparatus. James William Anderson, 60, Queen Victoria Street, London.

CURVE DRAWING.—No. 20,579. Improvements in photographic curve drawing apparatus. Siemens and Halske, Akt-Ges., Birkbeck Bank Chambers, London.

SHUTTERS.—No. 20,588. Improvements in photographic shutters. A. G. Boulton, 111, Hatton Garden, London, for Gustav Fischer, Germany.

COLOUR PHOTOGRAPHY.—No. 20,662. Improvements in colour photography. John Hutchinson P. wrie, 1, Broad Street Buildings, Liverpool Street, London.

SHUTTER.—No. 20,745. Roller blind shutter, with variable exposure slit, in which one portion of the blind is mounted on the supporting tapes of the other portion of the blind. Carl Sasse, 73, Cheapside, London.

APPARATUS.—No. 20,787. Improvements in photographic apparatus. Thomas Cumming Hinchlough and Harry Charles Moore, 6, Lord Street, Liverpool.

SHUTTERS.—No. 20,800. Improvements in photographic shutters. The Thornton-Pickard Manufacturing Co., Ltd., George Arthur Pickard and Frank Stringer, 5, Bank Street, Manchester.

FOCAL PLANE SHUTTERS.—No. 20,835. Improvements in focal plane shutters. Thomas Samuel Meldrum, 51, Deansgate Arcade, Manchester.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

ROLLER BLIND SHUTTERS.—No. 22,134, 1904. The patent is for a system of controlling the width of slit and motion of the blind of the shutter by an endless chain moving over the ends of the blind rollers. The blind is mounted on rollers fitted into

the casing A. Its lower portion, C., is attached to a roller B., which contains a spiral driving spring, and the upper portion C¹. is attached to the roller D. The two parts of the blind are connected by tapes E. and E¹, each of which is secured at one end to the edge of the upper part of the blind C¹, and, after passing through loops, or eyes, C². or C³, provided in the edge of the portion C., is continued on to a third roller F., to which it is fastened at F¹. or F². The rollers D. and F. are made to revolve in unison by means of the chain G., which engages with teeth formed on edges of drums H. and H¹, attached to ends of the rollers. A suitable clutch is fitted between the drum H. and the roller F., and when this is put out of gear with the roller the latter may be revolved by means of the milled head I.,

without at the same time turning roller D. The revolving of the roller F. causes the tapes E. and E¹. to be wound round the roller, and as a consequence draws the lower part C. of the blind nearer to the part C¹. The intervening space between the two portions of the blind may, by winding the tapes on, or off, the roller F., be made as large or as small as desired, and so alter the duration of an exposure. The roller D. is furnished with a toothed wheel or drum J., and a similar wheel J¹. is fitted to the lower roller B., but in such a manner that it may revolve quite freely. An endless chain K., on which are formed stops as K¹, intended to be arrested by another part of the shutter mechanism when it is desired to check the motion of the blind. The shutter is set ready for an exposure by winding, by means of knob L., the blind C¹, and part of the tapes around the roller D. To make the exposure the lever N. is moved about its fulcrum, so as to disengage the pawl M¹. from the ratchet wheel M., and the blind is drawn down by the spring of the roller B., and as it becomes wound round this latter roller causes the opening between the two portions of the blind to pass across the shutter opening, and thus exposing the plate. William Frederick Giles, 15, Bulmers Road, Reading.

FOCAL-PLANE SHUTTER.—No. 22,318, 1904. The claims are for a construction of a focal-plane shutter occupying little space, and made for ready adjustment from the outside. Also for a camera of more compact form. The focal-plane blind or shutter is provided with a compound roller comprising two tubular end sections and a tubular intermediate section, all mounted upon a central longitudinally movable spring-controlled stem furnished with bosses or collars with which the adjacent ends of the tubular sections engage and with which they normally turn, one of the collars having arms with which a spring bolt on the body of the camera is adapted to engage for preventing the intermediate portion of the tubular sections from revolving while the end portions revolve. The mechanism requires reference to the drawings for its proper explanation. Benjamin Joseph Edwards, Wistowe, Hayes.

A DEVELOPING BOX.—No. 22,429, 1904. The claim is for a box provided with window, sleeves, etc., and with an aperture to receive a camera or lens. Development is to be done in the box, which may be made of two hinged compartments like a Gladstone bag. Jethro Marsh, 61, King Edward Road, South Hackney, London.

COATING PAPER, ETC.—No. 1,290, 1905. The claim is for a new medium or vehicle for sensitive silver and other preparations to be used in the place of gelatine for gaslight paper, printing-out, and self-toning papers, etc. A mucilage of bassora, tragacanth, marsh mallow root, linseed, seeds of the plantain or plantago psyllium, quince seeds, is combined with a solution of agar-agar. In this combination the setting or gelatinising properties of the agar-agar are combined with the special plastic qualities of the bassorine or bassorine-like mucilage, the resulting product being a medium, vehicle, or coating composition which is soft and plastic, yet sufficiently insoluble, when dry. James Harris Paul Gillard, 2, Beaufort Villas, Sandycroft Road, Kew Gardens, and Henry Hearn Molyneux, Rathleigh Gate, West End Lane, West Hampstead.

News and Notes.

Mr. F. C. HART has resigned the position of hon. secretary to the West London Photographic Society, and his place has been taken by Mr. G. F. Perrins, 20, Rockley Road, West Kensington.

A FOCUSING Screen for Use in Photographing Ultra-violet Spectra.—Prof. W. N. Hartley writes to "Nature": "The sensitive surface upon which Stokes projected the ultra-violet rays when observing metallic lines and absorption spectra consisted of a plate of plaster of Paris moistened with a paste of uranium phosphate acidified with phosphoric acid ('Journ. Chem. Soc.' vol. xvii., 1864). Soret used uranium glass and solutions of fluorescent substances, such as asculine in liquid cells. I have found that the most convenient and effective screen for examining spectra with a quartz spectrograph is one such as is used for the X-rays. It may be made as follows: A photographic plate is first cleared of silver bromide by fixing and washing, and when the film is partly dry, but the gelatin still soft, it is dusted over with a powder of barium platinocyanide crystals, so as to be somewhat thickly coated with the salt. This is fixed in the dark slide of the camera. To focus a spectrum, the slide is tilted to the necessary angle, and a somewhat powerful focussing glass with a flat field is applied to the uncoated surface of the plate, when both the visible and ultra-violet spark spectra may be plainly seen by transmission, the latter by reason of the fluorescence excited. The focussing glass should be first carefully adjusted for any visible object on the other side of a plain glass plate, such as a fine hair fastened upon it, and the position of the eye-piece is then fixed. Suitable focussing glasses are those made by Dallmeyer and by Taylor, Taylor, and Hobson. When the spectrograph has been adjusted by means of the screen, the ultra-violet lines appear quite as sharp as those in the red and yellow, even the details in the group of cadmium lines between wave lengths 2,100 and 2,400 are well defined, and a very fair photograph may be obtained; but for the most accurate focussing photography must be resorted to.

A PHOTOGRAPHIC Section is announced for the forthcoming Armagh Agricultural Association. Particulars can be obtained from the Secretary, Albert E. Craddock, 10, College Street, Armagh.

THE Late Sir Henry Irving's Photograph.—Mr. William Crooke has appealed against Lord Ardwell's decision assailing the defenders

in the action against the Scots Pictorial Publishing Company, Ltd., with reference to the copyright of a photograph of the late Sir Henry Irving.

LOUGHTON Photographic Society.—At a meeting held at the Club, Loughton, on Friday, October 20, it was decided to form a photographic society for Loughton and district. Mr. J. T. Ashby, F.R.P.S., was elected president, Mr. Ernest Marriage, F.R.P.S., treasurer, and a committee of six members, with Mr. H. B. Peck as hon. sec. Ladies and gentlemen interested can obtain all particulars from the hon. sec. at Beverley, Church Hill, Loughton, Essex.

HOUGHTONS LTD. ask us to announce that they are giving demonstrations of their "Ideal Flash Lamp" at 88-89, High Holborn, on Tuesday mornings at eleven o'clock and Thursday afternoons at six o'clock. The Ideal Flash Lamp is particularly adapted for use in the studio, and all professionals who are in town should endeavour to call and inspect it. Absence of smoke, large area of lighting, and rapidity and brilliance of the flash are some of the chief attributes of this apparatus.

Commercial & Legal Intelligence

CLAIM for Non-delivery.—At the Burton County Court on Wednesday, Albert Kinsey, of Church Gresley, sued Messrs. A. G. Taylor, photographers, of Derby, for £1 17s. 6d., claim for non-delivery of a picture. For the plaintiff it was stated that the picture was ordered some considerable time ago, and though some cabinet photographs, ordered at the same time, were sent, the picture had not been forwarded. Defendants' representative admitted that the picture was not sent, as it was not completed when some premises were taken over. The value of the cabinet photographs was 5s. 6d. Judgment was given for plaintiff for £1 12s. and costs, the balance after deducting the value of the cabinet photographs.

FALSE Pretences.—A young man named Leopold Pitt appeared before the Cardiff magistrates on Saturday on a charge of obtaining 3s. 6d. by false pretences from Sam Smith, of the London Artistic Photographic Company, 134, Castle Road, Cardiff. On October 3 he had been appointed agent for the prosecutor to canvass for enlargement orders at Abertridwr at a salary of 10s. a week and 15 per cent. commission on orders. He was alleged to have obtained commission on spurious orders. Prisoner was fined £1; in default, seven days.

A Bogus Photographic Canvasser.—At the West London Police-court on Monday, before Mr. Lane, K.C., Ernest Hopper, 28, a traveller, living at 79, Simmerston Street, Chelsea, was charged, on remand, with obtaining 7s. 6d. by false pretences from Miss Jean Williams, of 40, Kensington Park Gardens. The prisoner called at the house on the pretence that he was a canvasser in the employment of Mr. Mallia, an Oxford Street photographer, and obtained an order and the money therefor. He declared at the last hearing that he took that and other orders for a man named Davis, who was in Mr. Mallia's employment. Evidence was given by Charles Davis, commission agent, living at 27, Darling Street, Walworth, who stated that he was formerly employed by Mr. Mallia, and he used to engage the prisoner as sub-agent to bring him orders. He had not seen him since August 22, and never gave him authority to get orders for him since then. Prisoner: If the witness had met me this would not have happened. We used to meet twice a day, and then I gave him the orders and he gave me the commission. He suddenly disappeared, and I had to use his name to get the orders. I could not find him so as to give him the orders and the money. Miss Netta

Thomas, boarding-house keeper, of 62, Margaret Street, W., stated that on February 9 the prisoner called, and, representing that he was canvasser for Mme. Lintot, of Bond Street (photographer), she agreed to have six photographs of her sister taken and to pay 2s. 6d. deposit. For that purpose she handed him a sovereign, and he promised to get change. He went out and never returned. Leah Keridge, a servant at 12, Hill Street, Mayfair, said the prisoner called on October 9, and obtained an order for six small photographs and one large one. She agreed to pay him 6s. 6d., and gave him a sovereign. He went away to get change and never returned. Prisoner said he would plead guilty to all three charges, and he pleaded that he had a delicate wife to support. Detective-Sergeant Burnie said that thirty other cases of a similar nature could be brought against the prisoner. Detective-Sergeant Ebbage, "W" Division, stated that in 1903 the prisoner was sentenced at Lambeth to six months' hard labour for stealing a ring and embezzlement. Two previous convictions were then proved against him. Mr. Lane sentenced him to three months' hard labour on each charge, making nine months' imprisonment, with hard labour, in all.

DUROLITE, LIMITED.—Registered October 17, by F. H. Faram, 86, Leadenhall Street, E.C. Capital, £30,000, in £1 shares. Objects: To carry on the business of manufacturers of glass, durolite, china, tiles, pottery and earthenware, designers, artists, engravers, embossers, painters, photographers, stainers and decorators of such substances as aforesaid. Registered office, 86, Leadenhall Street, E.C.

AN INFRINGEMENT OF COPYRIGHT.—Before his Honour Judge Lush-Wilson, K.C., at Stonehouse County Court, on Monday, John Abrahams, 39, Catherine Street, Devonport, brought an action for £10 against J. Easden, Army and Navy Studio, 21, Union Street, Stonehouse, in regard to an infringement of copyright in a photograph memorial of Submarine A8, with portraits of the victims and survivors, the funeral procession, and the graves combined, and registered on June 21, 1905. Plaintiff stated that on June 16 he took a photograph of the grave in Plymouth cemetery of the victims of the disaster to Submarine A8. Shortly after he bought a pictorial postcard, which was a reproduction of a portion of his photograph, and the copyright of which he registered. The sale of his photograph was adversely affected by the sale of the picture postcard. William Henry Waterfield, a photographer, said he had compared defendant's postcard with plaintiff's picture, and had come to the conclusion that it was a reproduction. That was proved principally by the perspective, which could not possibly be exactly the same in two different photographs. Defendant stated that on June 15 he took several photographs of the funeral procession. He photographed the grave on the morning of June 17 between five and half-past five. He developed the negative on the same morning, and during the same day sold prints taken from it. About a fortnight later the negative was broken and the pieces thrown away. He took one print from the original negative, but did not know what had become of it. Defendant, cross-examined by Mr. Akaster as to why, when writing him on the matter, he said he took the photograph on the day of the funeral, he replied that he did so because he trespassed in the cemetery on the Saturday morning. He got in by climbing over the railings. Plaintiff recalled, said he took his photograph at 5 p.m. on the day of the funeral, and it was not published until the 21st. Mr. Akaster asked defendant whether he had ever infringed anyone else's copyright. He did not reply, and Mr. Prance said he understood there were proceedings pending against his client. Mrs. Easden corroborated her husband's evidence. Mrs. Venn, stewardess, Stonehouse Constitutional Club, said on the evening of June 17, defendant gave her a pictorial postcard of the grave, and

said he took the photograph early that morning. She produced the postcard. Mr. Browning, salesman to defendant, stated that he was sent out with postcards of the grave on the 19th. Mr. Waterfield, recalled, said if the picture had been taken at 5 a.m. the light on the subject would come from the quarter opposite to that from which it came on the previous evening. His Honour, giving judgment, said he had no doubt that defendant's picture was a reproduction of a portion of the photograph taken by plaintiff on June 16. He could not get over the evidence of his own eye-sight. He could not believe that the postcard was the result of an independent negative, taken not at the same time as plaintiff's picture, five o'clock in the afternoon, when the sun was in the west, but five o'clock in the early morning, when the sun was in the east, and when, therefore, if the photograph was taken, the sun must have been pointing directly towards the lens. If that was true, was it possible to reconcile the acknowledged production in those circumstances? There was an extraordinarily accurate similarity between the postcard and plaintiff's picture. He was sure Mrs. Venn believed herself to be speaking the truth absolutely, but about four months elapsed before either she or Mr. Browning was questioned about the matter, and it was quite possible their memories were at fault. Defendant's answer to the claim was unsatisfactory, and he could not accept it. The documents spoke for themselves. He therefore, gave judgment for plaintiff for the injunction and damages claimed, with costs.

At the Burton Bankruptcy Court on Wednesday last, George Renwick, who had carried on the business of a photographer in Station Street, Burton, for many years, came up for examination, his liabilities being returned at £99 2s., and assets £19 7s. 7d., less £5 7s. for preferential creditors, leaving a net deficiency of £85 1s. 5d. An adjournment for a month, was granted.

ALLEGED PHOTOGRAPHIC FRAUD.—At Chelmsford, George Ash, alias J. Roberts, described as a canvasser, of Brixton, was charged last week with obtaining various sums of money by fraudulent means, at Springfield, Great Baddow, etc. According to the prosecution, the prisoner appeared to have called at various houses, offering to have any photograph enlarged for a small sum, on the purchase of a frame, and it was alleged that he received sums on deposit, and failed to execute the orders. Prisoner was committed for trial at the Essex Quarter Sessions.

CERIO PHOTO PRINTING COMPANY, LIMITED.—Registered October 13. Capital £15,000, in £1 shares. Object, to acquire the sole right to purchase, use, and photographically print on certain paper and other materials prepared by a special process, to adopt an agreement with the Ceriotype Company, Limited, and to carry on the business of photographic printers, photographers, stationers, etc. No initial public issue. The first directors (to number not less than three nor more than seven) are B. Fell, J. C. Mengel, E. Goddard, E. L. White, T. K. Grant, and C. Fitch. Qualification, £100. Remuneration as fixed by the company. Registered office: 23, Moorfields, E.C.

RE CHARLES HENRY BURNABY, 1, Chepstow Road, Croydon.—The above-named debtor appeared for his public examination at the last sitting of the Croydon Bankruptcy Court before the Registrar. The statement of affairs filed by the debtor disclosed liabilities amounting to £1,734, of which £219 was expected to rank, and a deficiency of £189. In reply to questions put by the Official Receiver, debtor said he was formerly in the employ of two photographic manufacturing companies as manager. Both those companies had now gone into liquidation. One of the companies was indebted to him in respect of services rendered to the extent of £118. His wife had a small private income. The examination was adjourned until November 8.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Oct.	Name of Society.	Subject.
27.....	Barrow Naturalists' Field Club	"The System of the Stars," Double Stars. Illustrated. Rev. T. E. B. Phillips, M.A.
27.....	Colne Camera Club.....	"Velox and its New Applications." Mr. A. Webb.
28.....	Sheffield Photographic Society	Third Annual Exhibition at the Montgomerie Hall.
30.....	Wallasey Amat. Photo. Soc.....	"Carbon Prints," Mr. J. H. Ormrod.
30.....	Widnes Photographic Society...	"Photography and the Press," Mr. Tomlin.
30.....	Barrow Naturalists' Field Club	"Marine Life." Illustrated by Microscopic and Lantern Slides. Mr. A. Scott, A. I. S.
30.....	Dewsbury Photo. Society.....	"Through Canada from the Atlantic to the Pacific." Mr. Ernest E. Slater.
30.....	Luton Camera Club	Demonstration. Messrs. Burroughes Wellcome & Co.
30.....	South London Photo. Society ..	"The Carbon Process," Mr. H. Creighton Beckett.
31.....	Barrow Naturalists' Field Club	Question Night. Members.
31.....	Halifax Camera Club	Conversational Evening with Demonstrations. 1. "Solo P.O.P." Mr. J. Peel. 2. "Passe Partout." Mr. G. R. Ryley. 3. "Lantern Slides by Contact." Mr. H. Lightowler.
31.....	Sunderland Camera Club	Beginners Night. 1. "How to Develop a Plate." Mr. K. S. Yeaman. 2. Gaslight Papers." Mr. C. B. Pinkney.
31.....	Darlington Camera Club	"Stories Without Words." Focus Prize Lectures.
31.....	Otley & Dis. Cam. & Art. Soc.	Demonstration. Mr. G. T. Woodley.
31.....	Gateshead Camera Club	"What Can be Done with a Hand Camera." Goetz Lecture, with Lantern Slide Illustrations. Messrs. Davidson and Miller.
31.....	Birmingham Photo. Society. ...	R.P.S. Affiliation Lecture.
31.....	Nelson Photographic Society	"Printing Processes." Demonstrated.
31.....	Jersey Photographic Society ..	"The English Lake District." Mr. P. H. Grandin.
31.....	Bristol Photographic Club	"Gum-Bichromatic Printing." Mr. C. H. Hewitt.
31.....	St. Helens Camera Club	"Gum-Bichromatic." Mr. J. Leyland.
31.....	Glasgow Eastern A.P.A	Visit to Glasgow Southern Photographic Association.
31.....	Thornton Heath Photo. Soc. ...	"Bromide Enlarging on Barnet Paper." The President.
Nov.		
1.....	Redhill and Dis. Camera Club.	"Landscape Photography." Mr. G. T. Harris.
1.....	Coventry Photo. Club	"Practical Enlarging." Mr. W. Riley.
1.....	Leeds Camera Club.....	"On the Fringe of the Austrian Alps." Illustrated. Mr. Charles B. Howdill.
1.....	North Middlesex Photo. Soc. ...	A.R.I.B.A.
1.....	Cricklewood Photo. Society.....	Lantern Slide (Architecture) and Print Competitions.
1.....	Edmonton and Dis. Ph. Soc.....	"Practical Photography." Messrs. Bridger, Carter, Ponsford, and Woolcott.
1.....	Croydon Camera Club	"Portraiture." Mr. Harold Baker.
1.....	G.E.R. Mechanics' Institution...	Competition: "Still Life."
1 to 4 ..	Hackney Photographic Society	"A New Bromide Printing Machine. Sulphide Toning of Bromide Prints" (Wellington & Ward). Mr. J. H. Avery.
2.....	Thornton Heath Photo. Society	R.P.S. Affiliation Competition Lantern Slides for 1905.
2.....	London and Prov. Photo. As...	Annual Exhibition.
2.....	Harrogate Camera Club	Solree Dansante.
2.....	Hull Photographic Society	"History of Gelatine Emulsion Plates." Mr. J. Burgess.
2.....	Balham Camera Club	Photography Prize Slides.
2.....	Chelsea and District Ph. Soc. ...	"Enlarged Negatives." Demonstrated. Mr. J. T. Dyson.
2.....	Liverpool Amateur Ph. Assn...	Members' Night.
2.....	Richmond Camera Club.....	"Photographs of Japan and the Japanese." Mr. E. J. Horniman, L.C.C.
2.....	Rodley Farsley & Calverley Dis.	"Six Hundred Miles up the Nile." Mr. G. E. Thompson.
2.....	Wimbledon and Dist. Cam. Club	Lantern Evening. Members' Slides.
2.....	Southport Photographic Soc.....	"Bromide Re-touching." Mr. J. Way.
2.....	Glasgow Eastern A.P.A.	"Stories without Words." Focus Prize Slides.
2.....		"A Visit to Spain to See the Solar Eclipse." D. E. Benson, A.M.I.C.E.
2.....		"Bromide Printing and Toning." Mr. J. Gillespie.

ROYAL PHOTOGRAPHIC SOCIETY.

On the 24th inst., at the New Gallery, 121, Regent Street, Mr. Chapman Jones, F.I.C., F.C.S., delivered the eighth Traill Taylor memorial lecture, entitled "Photography, the Servant of Science." The lecturer began with a brief and appreciative reference to the late J. Traill Taylor, who, he thought, had a distinct leaning

towards the use of photography for definitely useful or scientific purposes rather than for picture-making or empirical shots at the theories of photographic processes. The kind of photography the lecturer had in view, he said, was such as the student of architecture, the spectroscopist, the microscopist, and others ought to practise when they intend to give perfect renderings of the subjects with which they had to deal. He intended to treat of matters of fundamental importance, and considered that the lens should claim attention first. The matters that immediately concern the user of the lens are truth of outline, covering powers, definition, depth of definition, and the absence of false images and lights. To test for curvilinear distortion, he recommended that an equally divided scale line or lath be photographed, so that the image crossed the centre of the field, when, if the spaces were equally divided, distortion was absent. Errors in other directions might require special tests, though for general purposes there was no better test object than a flat wall covered with designs of the kind well known. As a test for definition he used a sheet of white card having on it groups of lines drawn with Indian ink, and having, in addition, fine holes pierced through. The lecturer challenged the statement that depth of definition depended absolutely on focal length and aperture. Theoretically no doubt it was so, but theory and practice only agreed so far as the axial rays were concerned. With regard to cameras, he considered that those of modern make were in many instances less reliable in holding the plate, so that its surface was perpendicular to the axis of the lens, than some of older type, and it was unfortunate that the deterioration of cameras should be contemporaneous with the improvement in lenses. In the estimation of plate speeds, while recognising the value of the work of Dr. Hurter and Mr. Driffell, he thought it was unfortunate that the object of it was the getting of an exact method of estimating general sensitiveness. He had found ordinary plates more sensitive to red than plates said to be red-sensitive and slow isochromatic plates more sensitive to green than other isochromatic plates labelled "specially rapid," etc. Under definite conditions, he said, every plate has a definite sensitiveness, though not to so minute a degree as many suppose. Want of permanency in a negative he considered to be want of truth, and emphasised the statement he had made long ago that a perfect negative must consist of pure silver in clean gelatine. Of development, he said that while variations in the negative can be made by development, few, he thought, made them when they thought they did. For most work he considered that a single solution (say, of metol) was all-sufficient. Acid fixing baths he condemned, and recommended a bath that contained sulphite and an alkali. For intensification, he considered the only reliable method was to bleach in mercuric chloride, and follow on with ferrous oxalate. Reducers, the lecturer thought, should not be used, since none can be depended upon to act proportionately. As to printing, he thought the best advice to a scientific worker was to avoid it. In a print the errors of the printing process are added to those of the negative.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEMBERS' meeting was held at the Royal Photographic Society on Friday, October 13, the President, Mr. T. C. Turner, in the chair.

The subject of discussion was the relationship of photographers with the Press. Reference was made to a newspaper paragraph in which a photographer at Rothesay was reported to have claimed £10 a copy from a Glasgow journal for an infringement of his copyright. The Judge dismissed the case on the ground that it could never have been intended by the law that a Court of Summary Jurisdiction—from the decision of which there was no appeal—should be competent to deal with a claim amounting to £250,000. The Presi-

dent strongly deprecated such claims for excessive damages, and thought the association should do all in its power to discourage such. At the same time it was necessary to assert one's rights, and to show newspaper proprietors that they could not help themselves to any photograph they pleased without reference to the owner.

Mr. Alfred Ellis said the daily Press had a grievance, for which there was some show of justification. They often wanted to reproduce a portrait of a person whom some event of the moment had brought into prominence. They complained that there was often no time to ask and obtain formal permission, and in some cases it was not possible to communicate with the owner of the copyright at once, because his address was not known, or for some such reason, and that on publishing the picture, intending in good faith to pay the usual fee as soon as opportunity occurred, the fee was declined, and they were treated as wilful infringers. There was, Mr. Ellis thought, hardship in some cases, but the difficulty was to find a system by which such cases might be met without giving those papers which had no such honest intentions the opportunity of sheltering themselves under the dispensation when found out. It had been suggested that if the newspapers would agree all to send a copy of the paper immediately upon publication to an official, whose duty it would be to look them over and note the copyright photographs published, it might meet the case.

The Assistant Secretary said the association, in dealing with infringements of copyright on behalf of its members, was very careful to distinguish between cases where there was no excuse for the infringement, and cases where there were extenuating circumstances. He then gave the particulars of three cases which the association had been able to settle during the past three months on terms which were satisfactory to the members involved, and which should be satisfactory to the other parties, as the amount accepted was only so much in excess of the usual fee as to mark the difference between the ordinary transaction and the settlement of a case where the right to recover a substantial penalty had been incurred. There were no law costs when the association dealt with the matter, so that the offending parties were not put to the usual expense which attends circumstances of the kind.

Mr. H. E. Hull thought it would promote harmony in the dealings between the Press and photographers if there existed a general agreement that all matters in dispute with regard to copyright should be referred to arbitration.

MEETING OF THE COMMITTEE.

A committee meeting was held on Friday, 13th inst., at the Royal Photographic Society, 66, Russell Square, W.C., previous to the members' meeting. Present: Messrs. T. C. Turner (Hull), A. Ellis, Wm. Grove, F. A. Bridge, Martin Jacolette, A. Mackie, S. Herbert Fry, H. E. Hull, H. S. Mendelssohn, D. Prodger, E. Scammell, Lang Sims, R. Fellows Willson, Wm. Gill (Colchester), H. A. Chapman (Swansea), and H. C. Spink (Brighton).

Mr. T. C. Turner (President) in the chair.

The President was invested with the gold presidential badge, subscribed for by the members of the committee.

The Secretary referred in sympathetic terms to Mr. A. England, of Barnet, a member who had been a constant attendant at the gatherings of the association, who had met with a severe accident, and stated that he had written in the name of the committee expressing their regret.

The publication of the first number of the "P.P.A. Circular," as authorised by the committee, was officially reported to the committee. The President expressed his opinion of its great usefulness, and said the publication of the steps taken by himself in Hull to circumvent the wiles of a firm of free portrait dodgers had led to a member in

another town adopting the same method, and, he believed, with complete success.

The Assistant Secretary reported that a circular had been drawn up briefly, setting forth the particulars of the association and its work and the advantages of membership. These were being distributed in likely quarters with a view of inducing photographers who were not members to join. The settlement of several cases of infringement of copyright and other disputes was reported. A discussion took place upon the certificate scheme, a year having elapsed since the institution of the system, and was adjourned to the next meeting.

The desirability of continuing the subscriptions of the three members representing the Association to the Artistic Copyright Society was considered, and it was decided to receive the subscriptions.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

Mr. J. C. S. MUMMERY, at the meeting held October 12, demonstrated the gum-bichromate process. In opening, he gave the history of the process, mentioning Pouncey's work, Swan's carbon process, and the resurrection of Pouncey's work in 1894. There were two methods of working—the single coating used by French workers, and the multiple coating used by German and British workers chiefly. Care must be taken in choice of paper, to select one which stretches and shrinks evenly. By previous wetting one can ensure correct register of subsequent printings. Either potassium or ammonium bichromate could be used for sensitising, the potassium salt being best for automatic development, and the ammonium bichromate better for brush work. A large range of colours could be employed, but for warm tones he used a mixture of black and red, rather than the browns. For coating he used gum 35 to 50 per cent., taking 40 grs. lampblack to the ounce, grinding in with a muller, and adding an equal quantity of saturated solution of bichromate. The coating had to be done rapidly, as the solution soon set. The paper was dried quickly, but must not be heated. The lecturer then showed his method of registering his prints. He used a drawing-board, with fillets on two sides, against which the paper was pushed, face up. Then two strips of carefully cut card were placed inside to give a white gauge, the negative then placed film down, the requisite pressure given by a sheet of $\frac{3}{4}$ -in. plate glass. Development was done either automatically by floating face down in cold water, or by laying sawdust soup, as in the Artigue process, with cotton wool or with a spray. Development should take only five to ten minutes, and it was better to let the print dry before using the alum to discharge the colour of the bichromate. The prints must be laid on blotting-paper to dry, as if they are hung up the paper stretches unevenly and destroys register for subsequent printing.

Mr. Teape asked what means the lecturer employed to avoid the coarse grain seen in so many exhibition prints. Mr. Mummery said under-exposure would cause it, as the print could not be developed right out, and over-exposure, in which case it would be due to friction. Mr. Teape asked how to remove undesirable obstacles in the picture. The answer was to block out and print in by the stencil method or dry after development, then soak and work with either sharpened match, brush, or stump. Mr. Bailey asked if it were possible to remove details with the spray, and was told that light detail could be removed, but dark parts always left a stain of the bichromate. Mr. Holding asked if greater depth could not be obtained by twice coating before printing. Answer: Probably not, as the first coating dissolved immediately; in any case, better to print twice or use a thicker coating. Very clear spots could be made by using more gum and taking out with brush, while the print was wet. To take out thin patches, the method was to coat locally, softening the edge with a dry brush, and print again. Asked how the effect was gained in two prints shown, one having light spots, the other not,

and yet showing detail in heavy shadows, Mr. Mummery said it was by carefully avoiding the part with the spray. The chairman proposed a hearty vote of thanks to Mr. Mummery for his demonstration, a proposition which was carried with acclamation.

CROYDON CAMERA CLUB.—A demonstration on the carbon process was given before the members of this club on Wednesday of last week by J. M. Sellors. The lecturer rather favoured commercial drawing-papers as single transfer, owing to the variety of surfaces obtainable. All drawing-papers, however, required a preliminary coating, the one recommended being: Nelson's No. 1 gelatine, 160 grains; water, 9 oz. Allow to swell, and dissolve over a water bath. A chrome-alum solution (9 grains in 3 oz.) is then gradually added, stirring vigorously the while. One coating, applied warm with a stiff brush for the smooth papers, and two for the rough, will be found sufficient. As regards transparencies, the special tissue should be employed, but if the negative were extremely hard, the ordinary tissue, he said, would be found to work best. Glasses with a thin insoluble substratum could be purchased from the Autotype Co., but a very good substratum could be easily made by adding the white of one egg well beaten up to a pint of water. Any sediment formed should be allowed to settle, and the clear portion decanted. The glasses could be dipped bodily into this solution, drained, and dried. In the discussion which followed, it was suggested that methylated spirits would advantageously be utilised for quickly drying carbon tissue. Mr. F. W. Hicks, however, was of a different opinion; the ordinary commercial spirit was so charged with foreign matter that its employment for this purpose was almost out of the question. Mr. H. P. C. Harpur stated that he would judge when printing was complete by breathing on the tissue, and inspecting a transient appearance of the image on its surface. The president, Mr. W. H. Smith, in answer to a question, stated that the "single tint" print-meters were undeniably more accurate in working than those depending upon figures or letters successively printing out.

HULL PHOTOGRAPHIC SOCIETY.—C. B. Howdill, A.R.I.B.A., who lectured last week before this Society on "Yorkshire Minsters," said it was not necessary for amateurs to go abroad to photograph architectural subjects with such delightful and beautiful examples so near home as Ripon, York, and Beverley. Mr. Godfrey Bingley, also lecturing on Warwickshire, Gloucestershire, and the Wye Valley, proved this district to be an ideal spot for both a holiday and the camera.

HEREFORDSHIRE PHOTOGRAPHIC SOCIETY.—The annual meeting of the members of this Society was held at Clarence House, Hereford, on Wednesday evening of last week. Mr. J. S. Arkwright, M.P., was elected president, and Messrs. Alfred Watkins, J. Parker, Mr. J. Humfrys, H. H. Parry, and Foster Shaw vice-presidents. Mr. W. E. Haines was re-elected treasurer, and Mr. Cecil Gethen secretary; Mr. W. Davies, librarian, and Mr. E. Horth, lanternist. On the council there were appointed Messrs. W. A. Roberts, Gus Edwards, W. T. Carless, S. Beeson, Marshall Q. Millar, Akast, W. W. Robinson, Derry, W. Williams, and E. Davies. The treasurer produced the accounts, showing a balance in hand, and the secretary gave a satisfactory report.

BLACKBURN CAMERA CLUB.—At a meeting of this club, held in the club rooms, Church Street, on Friday night, October 20, "The Gum Bichromate Process" was demonstrated by Dr. Ivatts.

WIMBLEDON AND DISTRICT CAMERA CLUB.—On October 19 a lecture on "Hampton Court Palace," illustrated by a large number of lantern slides, was given by the hon. secretary, Mr. J. Munro.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—Mr. F. Rust, of the Leeds Camera Club, gave a practical demon-

stration before the members of this society last week of his method of making enlarged negatives from an untuned P.O.P. print by reflected light. The lecturer's apparatus consisted of a large camera (to take a 15 by 12 negative) clamped on to a fairly long board. At one end of the board opposite the lens of the camera was fixed a 10 by 8 printing frame. This frame was fixed rigidly, with side struts so that it stood at right angles to the base board. In the frame a sheet of thin plate glass was used, and the untuned P.O.P. print from which the enlarged negative was to be made was held flat and central in the frame in contact with the glass in the ordinary way. Mr. Rust explained that an expensive camera was unnecessary for his method, and pointed out that a serviceable apparatus to take its place could be easily constructed out of an ordinary box, and himself used a dark slide made of picture frame moulding and cardboard. In using a box of this description the user's camera could be fixed to the front and thus supply the optical and focussing arrangements. After the print had been focussed to the desired size on the ground glass by the light of a taper or candle the plate was inserted and the exposure made. This was effected by burning magnesium ribbon. For an enlargement from half-plate to 15 by 12 in., using stop $f/11$, 15 in. of ribbon were burnt on both sides of the printing frame. An ingenious way of doing this was demonstrated. Two ordinary long steel hatpins were fixed at an angle of 45 deg. to the surface of the frame by sticking them into the woodwork so that the heads were well in front. Suspended from the ends of the pins were the strips of ribbon, but as these would be too long if held straight they were coiled round a piece of stick or lead pencil and released. They thus formed a sort of helical spiral and burnt very evenly. Pieces of card protected the lens from the glare of the light. Mr. Rust used "Castle" plates, well backed, and developed his exposures with Rodinal. The negatives produced were of excellent quality, retaining all the gradations of the original print. The lecturer claimed that this method was not only far more economical than producing enlarged negatives via a glass transparency, but that far more control was possible in the paper positive in the way of sunning down or printing in clouds, etc. Moreover, by always printing the P.O.P. to just the right depth required for the finished result the exposures necessary for making the enlarged negative were always the same, and by using the same stop, same degree of enlargement, and same length of magnesium ribbon, no error of judgment could creep in, and good results were to be depended upon in every case.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.—A demonstration of oil printing was given on October 17 by Mr. James Gale, of Wolverhampton. Mr. Gale referred to the possibilities of the process as a means of expressing personal feeling. In this respect it may be classed with gum bichromate. There is, however, an essential difference, for in gum we start with a pigmented surface in which also is the image, but in oil printing we apply the pigment to the image. In developing the image is not broken up as in gum, and unlimited alterations may be made in the layer of pigment without altering the image. Further, if we do not like the colour, the whole can be washed off and the image repigmented. As regards history, as early as 1855 Poitevin took out a patent for a process by which he obtained pictures by taking an exposed, chromated gelatinised film, and it is interesting to note that his patent also covered gum-bichromate. In 1904 Mr. G. E. H. Rawlins revived the process. As regards theory, a specially gelatinised basis is needed. This one can prepare oneself, though Mr. Gale did not recommend doing so—a paper has been recently introduced by Elliott and Son which gives good results. It can be had sensitive or insensitive. Sensitising is the same as for carbon tissue. This sensitive surface is then exposed under the negative (which should have good contrast) until the

details are visible, showing as a brownish image on a yellow ground. Printing is very rapid, and should not be carried too far. By exposure, the gelatine surface in those parts acted on by light—e.g., the shadows—becomes hard and insoluble, while the protected parts—e.g., the high lights—remain soft and absorbent. If the print is allowed to soak in water, the soft parts will absorb water, the hard parts will not. This soaking is best done in cold water for two or three hours; though warm water may be used for a shorter time. Soaking should continue until the image shows distinctly in relief. The print is then removed, and superfluous water taken off with a soft cloth. Then it is ready for pigmenting, which may be done at once, or any time afterwards; if allowed to become dry, preliminary soaking is necessary before pigmenting. The pigment may be either tube oil-colours or printers' ink of various colours. This costs about 2s. per lb., and a few ounces will do a great number of prints. A small quantity is taken on a piece of glass, and thinned with turpentine by means of a palette knife. The print is covered evenly with pigment by dabbing with a piece of cotton wool, the whole surface must be covered, and then it is rolled with a roller squeegee. What happens is that the parts saturated with water will throw off the pigment, leaving it only on the hard parts. In this way a picture is formed of any desired pigment held in position by oil, and having the gradation of the original negative. Rolling is best done on a slab of plate glass to ensure perfect flatness; before rolling, the turpentine must be allowed to evaporate. The paint may also be applied with a stencil brush, which is held perpendicularly and dropped lightly on the print, leaving behind each time a certain amount of pigment. The amount taken up is always proportional to the light action, which fact should be carefully borne in mind.

SOUTHAMPTON CAMERA CLUB.—Mr. V. E. Morris, of East Grinstead, lectured on and demonstrated the "Art of Lantern-Slide Making" to the members of the above on Monday, the 23rd inst., and was warmly welcomed by a good attendance. Among the many points urged by Mr. Morris were the following:—That the making of lantern slides must not be looked upon as a sort of by-product of photography, since it was possible in the best slides to obtain better tone gradation than in any print. He pointed out that the slightest defect in the slide was magnified on the screen to a serious blemish, and mentioned that in spotting black slides or negatives he had found, in spite of advice to the contrary, that a soft lead pencil, preferably a B.B., was the best means, since it enabled him to deal with the defect without the usual medium. In matters of exposure and development many hints were given. It was suggested that a negative of which correct exposure was to be found should be exposed in sections, 10 seconds one strip, the next 20, up to 40 for the fourth strip, and then, under normal conditions, the right exposure would be ascertained. In development, it was recommended that for black tones sufficient progress had been made when high lights began to veil, and warning was given that in warm-tone slide-making over-development was easily reached. When reduction was needed in the slide, great care was to be taken that slide be quite cleared of reducer before being held to light for examination. In the matter of putting in cloud negatives, which Mr. Morris fully demonstrated, the method recommended was to have the development done on the slide itself when making warm-toned slides for the consideration of getting proper tones, and on the cover glass when making black-toned slides. Mr. Morris illustrated his lecture from his own slides, producing special slides for the purpose of illustrating faults and varieties of masking. The lecture was listened to with marked interest, and the lecturer was most heartily thanked by those present.

The concluding article by "Hon. Sec." on "Photographic Societies," is crowded out from our columns this week for lack of space.
